- 2.* MFT uses a few features of the local Pascal compiler that may need to be changed in other installations:
 - 1) Case statements have a default.
 - 2) Input-output routines may need to be adapted for use with a particular character set and/or for printing messages on the user's terminal.

These features are also present in the Pascal version of T_EX , where they are used in a similar (but more complex) way. System-dependent portions of MFT can be identified by looking at the entries for 'system dependencies' in the index below.

The "banner line" defined here should be changed whenever MFT is modified.

```
define banner ≡ 'This, is, MFT, C, Version, 2.0'
```

3.* The program begins with a fairly normal header, made up of pieces that will mostly be filled in later. The MF input comes from files mf_file , $change_file$, and $style_file$; the TFX output goes to file tex_file .

If it is necessary to abort the job because of a fatal error, the program calls the ' $jump_out$ ' procedure, which goes to the label end_of_MFT .

```
⟨Compiler directives 4*⟩

program MFT;

const ⟨Constants in the outer block 8⟩

type ⟨Types in the outer block 12⟩

var ⟨Globals in the outer block 9⟩

⟨Error handling procedures 29⟩

⟨scan_args procedure 115*⟩

procedure initialize;

var ⟨Local variables for initialization 14⟩

begin ⟨Set initial values 10⟩

end;
```

4.* The Pascal compiler used to develop this system has "compiler directives" that can appear in comments whose first character is a dollar sign. In our case these directives tell the compiler to detect things that are out of range.

```
\langle Compiler directives 4^*\rangle \equiv This code is used in section 3^*.
```

The original Pascal compiler was designed in the late 60s, when six-bit character sets were common, so it did not make provision for lowercase letters. Nowadays, of course, we need to deal with both capital and small letters in a convenient way, especially in a program for font design; so the present specification of MFT has been written under the assumption that the Pascal compiler and run-time system permit the use of text files with more than 64 distinguishable characters. More precisely, we assume that the character set contains at least the letters and symbols associated with ASCII codes '40 through '176. If additional characters are present, MFT can be configured to work with them too.

Since we are dealing with more characters than were present in the first Pascal compilers, we have to decide what to call the associated data type. Some Pascals use the original name char for the characters in text files, even though there now are more than 64 such characters, while other Pascals consider char to be a 64-element subrange of a larger data type that has some other name.

In order to accommodate this difference, we shall use the name text_char to stand for the data type of the characters that are converted to and from ASCII_code when they are input and output. We shall also assume that text_char consists of the elements $chr(first_text_char)$ through $chr(last_text_char)$, inclusive. The following definitions should be adjusted if necessary.

```
define text\_char \equiv ASCII\_code { the data type of characters in text files }
  define first\_text\_char = 0 { ordinal number of the smallest element of text\_char }
  define last\_text\_char = 255 {ordinal number of the largest element of text\_char}
\langle \text{Types in the outer block } 12 \rangle + \equiv
  text\_file = packed file of text\_char;
```

17. The ASCII code is "standard" only to a certain extent, since many computer installations have found it advantageous to have ready access to more than 94 printing characters. If MFT is being used on a gardenvariety Pascal for which only standard ASCII codes will appear in the input and output files, it doesn't really matter what codes are specified in xchr[0...'37], but the safest policy is to blank everything out by using the code shown below.

However, other settings of xchr will make MFT more friendly on computers that have an extended character set, so that users can type things like '\(\frac{1}{2}\) instead of '<>', and so that MFT can echo the page breaks found in its input. People with extended character sets can assign codes arbitrarily, giving an xchr equivalent to whatever characters the users of MFT are allowed to have in their input files. Appropriate changes to MFT's char_class table should then be made. (Unlike TFX, each installation of METAFONT has a fixed assignment of category codes, called the *char_class*.) Such changes make portability of programs more difficult, so they should be introduced cautiously if at all.

```
\langle \text{ Set initial values } 10 \rangle + \equiv
   for i \leftarrow 1 to '37 do xchr[i] \leftarrow chr(i);
   for i \leftarrow 177 to 377 do xchr[i] \leftarrow chr(i);
```

20* Terminal output is done by writing on file $term_out$, which is assumed to consist of characters of type $text_char$:

```
 \begin{array}{l} \textbf{define} \ \ term\_out \equiv stdout \\ \textbf{define} \ \ print(\texttt{\#}) \equiv write(term\_out,\texttt{\#}) \quad \{ \ \ \ 'print' \ \  \, \text{means write on the terminal} \} \\ \textbf{define} \ \ print\_ln(\texttt{\#}) \equiv write\_ln(term\_out,\texttt{\#}) \quad \{ \ \ \ \ 'print' \ \  \, \text{and then start new line} \} \\ \textbf{define} \ \ new\_line \equiv write\_ln(term\_out) \quad \{ \ \  \, \text{start new line on the terminal} \} \\ \textbf{define} \ \ print\_nl(\texttt{\#}) \equiv \quad \{ \ \  \, \text{print information starting on a new line} \} \\ \textbf{begin} \ \ new\_line; \ \ print(\texttt{\#}); \\ \textbf{end} \\ \end{array}
```

21.* Different systems have different ways of specifying that the output on a certain file will appear on the user's terminal.

```
\langle \text{ Set initial values 10} \rangle + \equiv \{ \text{ nothing need be done } \}
```

22.* The *update_terminal* procedure is called when we want to make sure that everything we have output to the terminal so far has actually left the computer's internal buffers and been sent.

```
define update\_terminal \equiv flush(term\_out) { empty the terminal output buffer }
```

24.* The following code opens the input files. This is called after *scan_args* has set the file name variables appropriately.

```
procedure open_input; { prepare to read inputs }
  begin if test_read_access(mf_file_name, MF_INPUT_PATH) then reset(mf_file, mf_file_name)
  else begin print_pascal_string(mf_file_name); print(`:\_Metafont\_source\_file\_not\_found`); uexit(1);
  end;
  reset(change_file, change_file_name);
  if test_read_access(style_file_name, TEX_INPUT_PATH) then reset(style_file, style_file_name)
  else begin print_pascal_string(style_file_name); print(`:\_Style\_file\_file\_not\_found`); uexit(1);
  end;
  end;
```

26* The following code opens tex_file . The $scan_args$ procedure is used to set up tex_file_name as required. \langle Set initial values 10 \rangle + \equiv $scan_args$; $rewrite(tex_file, tex_file_name)$;

28* The $input_ln$ procedure brings the next line of input from the specified file into the buffer array and returns the value true, unless the file has already been entirely read, in which case it returns false. The conventions of T_EX are followed; i.e., $ASCII_code$ numbers representing the next line of the file are input into buffer[0], buffer[1], ..., buffer[limit-1]; trailing blanks are ignored; and the global variable limit is set to the length of the line. The value of limit must be strictly less than buf_size .

```
function input\_ln(\mathbf{var}\ f : text\_file): boolean; {inputs a line or returns false }
  var final_limit: 0 .. buf_size; { limit without trailing blanks }
  begin limit \leftarrow 0; final\_limit \leftarrow 0;
  if eof(f) then input\_ln \leftarrow false
  else begin while \neg eoln(f) do
        begin buffer[limit] \leftarrow xord[getc(f)]; incr(limit);
        if buffer[limit-1] \neq " \sqcup " then final\_limit \leftarrow limit;
        if limit = buf\_size then
           begin while \neg eoln(f) do vgetc(f);
           decr(limit); { keep buffer[buf_size] empty }
           if final\_limit > limit then final\_limit \leftarrow limit;
           print\_nl(`! \sqcup Input \sqcup line \sqcup too \sqcup long`); loc \leftarrow 0; error;
           end;
        end;
     read\_ln(f); limit \leftarrow final\_limit; input\_ln \leftarrow true;
  end;
```

31.* The $jump_out$ procedure cleans up, prints appropriate messages, and exits back to the operating system.

112* The main program. Let's put it all together now: MFT starts and ends here.

```
begin initialize; { beginning of the main program } print_ln(banner); { print a "banner line" } 
 \langle Store all the primitives 65\rangle; \langle Store all the translations 73\rangle; \langle Initialize the input system 44\rangle; do\_the\_translation; \langle Check that all changes have been read 49\rangle; \langle Print the job history 113\rangle; new\_line; if (history \neq spotless) \land (history \neq harmless\_message) then uexit(1) else uexit(0); end.
```

114* System-dependent changes.

The user calls MFT with arguments on the command line. These are either file names or flags (beginning with '-'). The following globals are for communicating the user's desires to the rest of the program. The various file_name variables contain strings with the full names of those files, as UNIX knows them.

The flags that affect MFT are -c and -s, whose statuses is kept in *no_change* and *no_style*, respectively. \langle Globals in the outer block $9 \rangle +\equiv$

mf_file_name, change_file_name, style_file_name, tex_file_name: packed array [1 .. FILENAMESIZE] of char:

no_change, no_style: boolean;

This code is used in section 3*.

The scan_args procedure looks at the command line arguments and sets the file_name variables accordingly.

At least one file name must be present as the first argument: the mf file. It may have an extension, or it may omit it to get '.mf' added. If there is only one file name, the output file name is formed by replacing the mf file name extension by '.tex'. Thus, the command line mf foo implies the use of the METAFONT input file foo.mf and the output file foo.tex. If this style of command line, with only one argument is used, the default style file, *plain.mft*, will be used to provide basic formatting.

An argument beginning with a hyphen is a flag. Any letters following the minus sign may cause global flag variables to be set. Currently, a c means that there is a change file, and an s means that there is a style file. The auxiliary files must of course appear in the same order as the flags. For example, the flag -sc must be followed by the name of the *style_file* first, and then the name of the *change_file*.

```
\langle scan\_args \text{ procedure } 115^* \rangle \equiv
procedure scan_args;
  var dot_pos, slash_pos, i, a: integer; { indices }
     which_file_next: char; fname: array [1...FILENAMESIZE] of char; { temporary argument holder }
     found_mf, found_change, found_style: boolean; { true when those file names have been seen }

     else \langle Handle flag argument in fname 121*\rangle;
  if \neg found\_mf then \langle Print usage error message and quit <math>122^* \rangle;
  end;
```

116.* Use all of fname for the mf_file_name if there is a ´.´ in it, otherwise add ´.mf´. The TEX file name comes from adding things after the dot. The argv procedure will not put more than FILENAMESIZE - 5 characters into fname, and this leaves enough room in the file_name variables to add the extensions. We declared fname to be of size FILENAMESIZE instead of FILENAMESIZE - 5 because the latter implies FILENAMESIZE must be a numeric constant—and we don't want to repeat the value from site.h just to save five bytes of memory.

The end of a file name is marked with a 'u', the convention assumed by the reset and rewrite procedures.

\langle Assign the default value to ilk[p] 63\rangle Used in section 62.
Branch on the class, scan the token; return directly if the token is special, or goto found if it needs to
    be looked up 81 \rangle Used in section 80.
(Bring in a new line of input; return if the file has ended 85) Used in section 80.
 Cases that translate primitive tokens 100, 101, 102, 103 \ Used in section 97.
 Change the translation format of tokens, and goto restart or reswitch 111 \( \) Used in section 97.
 Check that all changes have been read 49 \ Used in section 112*.
 Compare name p with current token, goto found if equal 61 \rangle Used in section 60.
 Compiler directives 4^* Used in section 3^*.
 Compute the hash code h 59 \ Used in section 58.
 Compute the name location p 60 \rangle Used in section 58.
 Constants in the outer block 8 \ Used in section 3*.
 Copy the rest of the current input line to the output, then goto restart 109 \> Used in section 97.
 Decry the invalid character and goto switch 84 \ Used in section 81.
 Decry the missing string delimiter and goto switch 83 \ Used in section 82.
 Do special actions at the start of a line 98 \ Used in section 97.
 Enter a new name into the table at position p 62 \quad Used in section 58.
 Error handling procedures 29, 31* \ Used in section 3*.
 Get a string token and return 82 \ Used in section 81.
 Get change_file_name from fname 117* Used in section 115*.
 Get mf\_file\_name from fname, and set up tex\_file\_name 116* \rightarrow Used in section 115*.
 Get style\_file\_name from fname 118* Used in sections 115* and 115*.
 Globals in the outer block 9, 15, 23, 25, 27, 34, 36, 51, 53, 55, 72, 74, 75, 77, 78, 86, 114* Used in section 3*.
 Handle flag argument in fname 121^* Used in section 115^*.
 If the current line starts with @y, report any discrepancies and return 43 \) Used in section 42.
 Initialize the input system 44 \rangle Used in section 112*.
 Local variables for initialization 14, 56 \ Used in section 3*.
 Move buffer and limit to change_buffer and change_limit 41 \ Used in sections 38 and 42.
 Print error location based on input buffer 30 \ Used in section 29.
 Print the job history 113 \rightarrow Used in sections 31^* and 112^*.
 Print usage error message and quit 122*) Used in sections 115* and 115*.
 Print warning message, break the line, return 92 \ Used in section 91.
 Read from change_file and maybe turn off changing 48 \rangle Used in section 45.
 Read from mf_file and maybe turn on changing 46 \) Used in section 45.
 Read from style_file and maybe turn off styling 47 \> Used in section 45.
 Scan the file name and output it in typewriter type 104 \ Used in section 103.
 Set initial values 10, 16, 17*, 18, 21*, 26*, 54, 57, 76, 79, 88, 90 \ Used in section 3*.
 Set up null change file 119* \rightarrow Used in section 115*.
 Set up plain style file 120* Used in section 115*.
 Skip over comment lines in the change file; return if end of file 39 \ Used in section 38.
 Skip to the next nonblank line; return if end of file 40 \) Used in section 38.
 Store all the primitives 65, 66, 67, 68, 69, 70, 71 \ Used in section 112*.
 Store all the translations 73 \ Used in section 112*.
 Translate a comment and goto restart, unless there's a | ... | segment 108 \rangle Used in section 97.
 Translate a numeric token or a fraction 105 \ Used in section 97.
 Translate a string token 99 \ Used in section 97.
 Translate a subscript 107 \rangle Used in section 106.
 Translate a tag and possible subscript 106 \ Used in section 97.
 Types in the outer block 12, 13^*, 50, 52 Used in section 3^*.
(Wind up a line of translation and goto restart, or finish a | ... | segment and goto reswitch 110)
    Used in section 97.
\langle scan\_args \text{ procedure } 115^* \rangle Used in section 3*.
```

The MFT processor

(Version 2.0, October 1989)

	Section	on Page
Introduction		
The character set	1	11 403
Input and output	1	19 404
Reporting errors to the user		
Inserting the changes	3	34 407
Data structures	5	50 407
Initializing the primitive tokens	6	63 - 407
Inputting the next token	7	75 407
Low-level output routines	8	86 407
Translation	9	97 407
The main program		
System-dependent changes	11	14 408
Index	12	23 413
