texi.info

1.1   texi.info

```
                Texinfo
*******

   Texinfo is a documentation system that uses a single source file to
produce both on-line information and printed output.

   The first part of this master menu lists the major nodes in this Info
document, including the @-command and concept indices.  The rest of the
menu lists all the lower level nodes in the document.

   This is Edition 2.18 of the Texinfo documentation, 26 March 1993,
for Texinfo Version 2.

1.2 texi.info/Copying

Texinfo Copying Conditions
****

   The programs currently being distributed that relate to Texinfo
include portions of GNU Emacs, plus other separate programs (including
makeinfo, info, texindex, and texinfo.tex). These programs are free;
this means that everyone is free to use them and free to redistribute
them on a free basis. The Texinfo-related programs are not in the
public domain; they are copyrighted and there are restrictions on their
distribution, but these restrictions are designed to permit everything
that a good cooperating citizen would want to do. What is not allowed
is to try to prevent others from further sharing any version of these

programs that they might get from you.

   Specifically, we want to make sure that you have the right to give
away copies of the programs that relate to Texinfo, that you receive
source code or else can get it if you want it, that you can change these
programs or use pieces of them in new free programs, and that you know
you can do these things.

   To make sure that everyone has such rights, we have to forbid you to
deprive anyone else of these rights. For example, if you distribute
copies of the Texinfo related programs, you must give the recipients all
the rights that you have. You must make sure that they, too, receive or
can get the source code. And you must tell them their rights.

   Also, for our own protection, we must make certain that everyone
finds out that there is no warranty for the programs that relate to
Texinfo. If these programs are modified by someone else and passed on,
we want their recipients to know that what they have is not what we
distributed, so that any problems introduced by others will not reflect
on our reputation.

   The precise conditions of the licenses for the programs currently
being distributed that relate to Texinfo are found in the General Public
Licenses that accompany them.

1.3 texi.info/Overview

                   Overview of Texinfo
****

   Texinfo (1) is a documentation system that uses a single source file
to produce both on-line information and printed output. This means
that instead of writing two different documents, one for the on-line
help or other on-line information and the other for a typeset manual or
other printed work, you need write only one document. When the work is
revised, you need revise only one document. (You can read the on-line
information, known as an Info file, with an Info documentation-reading
program.)

                  Using Texinfo
                              Create a conventional printed book
                                or an Info file.

                  Info Files
                                   What is an Info file?

                  Printed Books
                              Characteristics of a printed book or manual.

                  Formatting Commands
                            @-commands are used for formatting.

               Conventions

                         General rules for writing a Texinfo file.

               Comments

                           How to write comments and mark regions that
                         the formatting commands will ignore.

               Minimum

                          What a Texinfo file must have.

               Six Parts

                         Usually, a Texinfo file has six parts.

               Short Sample
                         A short sample Texinfo file.

               Acknowledgements
                  ---------- Footnotes ----------

   (1) Note that the first syllable of "Texinfo" is pronounced like
"speck", not "hex". This odd pronunciation is derived from, but is not
the same as, the pronunciation of TeX. In the word TeX, the X is
actually the Greek letter "chi" rather than the English letter "ex".
Pronounce TeX as if the X were the last sound in the name 'Bach'; but
pronounce Texinfo as if the x were a 'k'. Spell "Texinfo" with a
capital "T" and write the other letters in lower case.

1.4 texi.info/Using Texinfo

               Using Texinfo
=============

   Using Texinfo, you can create a printed document with the normal
features of a book, including chapters, sections, cross references, and
indices. From the same Texinfo source file, you can create a
menu-driven, on-line Info file with nodes, menus, cross references, and
indices. You can, if you wish, make the chapters and sections of the
printed document correspond to the nodes of the on-line information;
and you use the same cross references and indices for both the Info
file and the printed work. 'The GNU Emacs Manual' is a good example of
a Texinfo file, as is this manual.

   To make a printed document, you process a Texinfo source file with
the TeX typesetting program. This creates a DVI file that you can
typeset and print as a book or report. (Note that the Texinfo language
is completely different from TeX's usual language, PlainTeX, which
Texinfo replaces.) If you do not have TeX, but do have troff or nroff,
you can use the texi2roff program instead.

   To make an Info file, you process a Texinfo source file with the
makeinfo utility or Emacs's texinfo-format-buffer command; this creates
an Info file that you can install on-line.

   TeX and texi2roff work with many types of printer; similarly, Info
works with almost every type of computer terminal. This power makes
Texinfo a general purpose system, but brings with it a constraint,
which is that a Texinfo file may contain only the customary
"typewriter" characters (letters, numbers, spaces, and punctuation
marks) but no special graphics.

   A Texinfo file is a plain ASCII file containing text and @-commands
(words preceded by an @) that tell the typesetting and formatting
programs what to do. You may edit a Texinfo file with any text editor;
but it is especially convenient to use GNU Emacs since that editor has
a special mode, called Texinfo mode, that provides various
Texinfo-related features. (See
                Texinfo Mode
                .)

   Before writing a Texinfo source file, you should become familiar with
the Info documentation reading program and learn about nodes, menus,
cross references, and the rest. (See info, for more information.)

   You can use Texinfo to create both on-line help and printed manuals;
moreover, Texinfo is freely redistributable. For these reasons, Texinfo
is the format in which documentation for GNU utilities and libraries is
written.

1.5   texi.info/Info Files

Info files
==========

   An Info file is a Texinfo file formatted so that the Info
documentation reading program can operate on it. (makeinfo and
texinfo-format-buffer are two commands that convert a Texinfo file into
an Info file.)

   Info files are divided into pieces called nodes, each of which
contains the discussion of one topic. Each node has a name, and
contains both text for the user to read and pointers to other nodes,
which are identified by their names. The Info program displays one node
at a time, and provides commands with which the user can move to other
related nodes.

   See info, for more information about using Info.

   Each node of an Info file may have any number of child nodes that
describe subtopics of the node's topic. The names of child nodes are
listed in a menu within the parent node; this allows you to use certain
Info commands to move to one of the child nodes. Generally, an Info
file is organized like a book. If a node is at the logical level of a
chapter, its child nodes are at the level of sections; likewise, the
child nodes of sections are at the level of subsections.

   All the children of any one parent are linked together in a

bidirectional chain of 'Next' and 'Previous' pointers. The 'Next'
pointer provides a link to the next section, and the 'Previous' pointer
provides a link to the previous section. This means that all the nodes
that are at the level of sections within a chapter are linked together.
Normally the order in this chain is the same as the order of the
children in the parent's menu. Each child node records the parent node
name as its 'Up' pointer. The last child has no 'Next' pointer, and the
first child has the parent both as its 'Previous' and as its 'Up'
pointer.(1)

   The book-like structuring of an Info file into nodes that correspond
to chapters, sections, and the like is a matter of convention, not a
requirement. The 'Up', 'Previous', and 'Next' pointers of a node can
point to any other nodes, and a menu can contain any other nodes.
Thus, the node structure can be any directed graph. But it is usually
more comprehensible to follow a structure that corresponds to the
structure of chapters and sections in a printed book or report.

   In addition to menus and to 'Next', 'Previous', and 'Up' pointers,
Info provides pointers of another kind, called references, that can be
sprinkled throughout the text. This is usually the best way to
represent links that do not fit a hierarchical structure.

   Usually, you will design a document so that its nodes match the
structure of chapters and sections in the printed output. But there
are times when this is not right for the material being discussed.
Therefore, Texinfo uses separate commands to specify the node structure
for the Info file and the section structure for the printed output.

   Generally, you enter an Info file through a node that by convention
is called Top. This node normally contains just a brief summary of the
file's purpose, and a large menu through which the rest of the file is
reached. From this node, you can either traverse the file
systematically by going from node to node, or you can go to a specific
node listed in the main menu, or you can search the index menus and
then go directly to the node that has the information you want.

   If you want to read through an Info file in sequence, as if it were a
printed manual, you can get the whole file with the advanced Info
command g* RET. (See Advanced Info commands.)

   The dir file in the info directory serves as the departure point for
the whole Info system. From it, you can reach the 'Top' nodes of each
of the documents in a complete Info system.

   ---------- Footnotes ----------

   (1) In some documents, the first child has no 'Previous' pointer.
Occasionally, the last child has the node name of the next following
higher level node as its 'Next' pointer.

1.6   texi.info/Printed Books

                    Printed Books
=============

   A Texinfo file can be formatted and typeset as a printed book or
manual. To do this, you need TeX, a powerful, sophisticated typesetting
program written by Donald Knuth.(1)

   A Texinfo-based book is similar to any other typeset, printed work:
it can have a title page, copyright page, table of contents, and
preface, as well as chapters, numbered or unnumbered sections and
subsections, page headers, cross references, footnotes, and indices.

   You can use Texinfo to write a book without ever having the intention
of converting it into on-line information. You can use Texinfo for
writing a printed novel, and even to write a printed memo, although
this latter application is not recommended since electronic mail is so
much easier.

   TeX is a general purpose typesetting program. Texinfo provides a
file called texinfo.tex that contains information (definitions or
macros) that TeX uses when it typesets a Texinfo file.
(texinfo.tex tells TeX how to convert the Texinfo @-commands
to TeX commands, which TeX can then process to create the typeset
document.) texinfo.tex contains the specifications for printing a
document.

   Most often, documents are printed on 8.5 inch by 11 inch pages
(216mm by 280mm; this is the default size), but you can also print for
7 inch by 9.25 inch pages (178mm by 235mm; the @smallbook size) or on
European A4 size paper (@afourpaper). (See Printing .
Also, see
                    Printing on A4 Paper
                    .)

   By changing the parameters in texinfo.tex, you can change the size
of the printed document. In addition, you can change the style in
which the printed document is formatted; for example, you can change the
sizes and fonts used, the amount of indentation for each paragraph, the
degree to which words are hyphenated, and the like. By changing the
specifications, you can make a book look dignified, old and serious, or
light-hearted, young and cheery.

   TeX is freely distributable. It is written in a dialect of Pascal
called WEB and can be compiled either in Pascal or (by using a
conversion program that comes with the TeX distribution) in C. (See
TeX Mode, for information about TeX.)

   TeX is very powerful and has a great many features. Because a
Texinfo file must be able to present information both on a
character-only terminal in Info form and in a typeset book, the
formatting commands that Texinfo supports are necessarily limited.

   See
                    How to Obtain TeX
                    .

   ---------- Footnotes ----------

(1)   You can also use the texi2roff program if you do not have TeX;
since Texinfo is designed for use with TeX, texi2roff is not described
here.   texi2roff is part of the standard GNU distribution.

1.7 texi.info/Formatting Commands

                              ==========

   In a Texinfo file, the commands that tell TeX how to typeset the
printed manual and tell makeinfo and texinfo-format-buffer how to
create an Info file are preceded by @; they are called @-commands.
For example, @node is the command to indicate a node and @chapter is
the command to indicate the start of a chapter.

     Please note: All the @-commands, with the exception of the @TeX{}
     command, must be written entirely in lower case.

   The Texinfo @-commands are a strictly limited set of constructs. The
strict limits make it possible for Texinfo files to be understood both by
TeX and by the code that converts them into Info files. You can
display Info files on any terminal that displays alphabetic and numeric
characters. Similarly, you can print the output generated by TeX on a
wide variety of printers.

   Depending on what they do or what arguments(1) they take, you need
to write @-commands on lines of their own or as part of sentences:

   * Write a command such as @noindent at the beginning of a line as
     the only text on the line. (@noindent prevents the beginning of
     the next line from being indented as the beginning of a paragraph.)

   * Write a command such as @chapter at the beginning of a line
     followed by the command's arguments, in this case the chapter
     title, on the rest of the line. (@chapter creates chapter
     titles.)

   * Write a command such as @dots{} wherever you wish but usually
     within a sentence. (@dots{} creates dots ...)

   * Write a command such as @code{sample-code } wherever you wish
     (but usually within a sentence) with its argument, sample-code in
     this example, between the braces. (@code marks text as being
     code.)

   * Write a command such as @example at the beginning of a line of
     its own; write the body-text on following lines; and write the
     matching @end command, @end example in this case, at the
     beginning of a line of its own after the body-text. (@example ...
      @end example indents and typesets body-text as an example.)

As a general rule, a command requires braces if it mingles among other
text; but it does not need braces if it starts a line of its own. The

non-alphabetic commands, such as @:, are exceptions to the rule; they
do not need braces.

   As you gain experience with Texinfo, you will rapidly learn how to
write the different commands: the different ways to write commands make
it easier to write and read Texinfo files than if all commands followed
exactly the same syntax. (For details about @-command syntax, see

              @-Command Syntax
              .)

   ---------- Footnotes ----------

   (1) The word argument comes from the way it is used in mathematics
and does not refer to a disputation between two people; it refers to the
information presented to the command. According to the 'Oxford English
Dictionary', the word derives from the Latin for to make clear, prove;
thus it came to mean 'the evidence offered as proof', which is to say,
'the information offered', which led to its mathematical meaning. In
its other thread of derivation, the word came to mean 'to assert in a
manner against which others may make counter assertions', which led to
the meaning of 'argument' as a disputation.

1.8 texi.info/Conventions

                    General Syntactic Conventions
==============================

   All ASCII printing characters except @, { and } can appear in a
Texinfo file and stand for themselves.   @ is the escape character
which introduces commands. { and } should be used only to surround
arguments to certain commands. To put one of these special characters
into the document, put an @ character in front of it, like this: @@,
, and @}.

   It is customary in TeX to use doubled single-quote characters to
begin and end quotations: ' ' and ' ' (but without a space between the
two single-quote characters). This convention should be followed in
Texinfo files. TeX converts doubled single-quote characters to left-
and right-hand doubled quotation marks and Info converts doubled
single-quote characters to ASCII double-quotes: ' ' and ' ' to " .

   Use three hyphens in a row, --, for a dash--like this. In TeX, a
single or even a double hyphen produces a printed dash that is shorter
than the usual typeset dash. Info reduces three hyphens to two for
display on the screen.

   To prevent a paragraph from being indented in the printed manual, put
the command @noindent on a line by itself before the paragraph.

   If you mark off a region of the Texinfo file with the @iftex and
 @end iftex commands, that region will appear only in the printed copy;
in that region, you can use certain commands borrowed from PlainTeX

that you cannot use in Info. Likewise, if you mark off a region with
the @ifinfo and @end ifinfo commands, that region will appear only in
the Info file; in that region, you can use Info commands that you
cannot use in TeX. (See
                Conditionals
                .)

    Caution: Do not use tabs in a Texinfo file! TeX uses
    variable-width fonts, which means that it cannot predefine a tab
    to work in all circumstances. Consequently, TeX treats tabs like
    single spaces, and that is not what they look like.

    To avoid this problem, Texinfo mode causes GNU Emacs to insert
    multiple spaces when you press the TAB key.

    Also, you can run untabify in Emacs to convert tabs in a region to
    multiple spaces.

1.9   texi.info/Comments

```
Comments
========
```

    You can write comments in a Texinfo file that will not appear in
either the Info file or the printed manual by using the @comment
command (which may be abbreviated to @c). Such comments are for the
person who reads the Texinfo file. All the text on a line that follows
either @comment or @c is a comment; the rest of the line does not
appear in either the Info file or the printed manual. (Often, you can
write the @comment or @c in the middle of a line, and only the text
that follows after the @comment or @c command does not appear; but
some commands, such as @settitle and @setfilename, work on a whole
line. You cannot use @comment or @c in a line beginning with such a
command.)

    You can write long stretches of text that will not appear in either
the Info file or the printed manual by using the @ignore and @end
ignore commands. Write each of these commands on a line of its own,
starting each command at the beginning of the line. Text between these
two commands does not appear in the processed output. You can use
applies to the Texinfo source file of a document, but not to the Info
or printed version of the document.

1.10   texi.info/Minimum

```
                What a Texinfo File Must Have
=============================
```

    By convention, the names of Texinfo files end with one of the

extensions .texinfo, .texi, or .tex. The longer extension is preferred
since it describes more clearly to a human reader the nature of the
file. The shorter extensions are for operating systems that cannot
handle long file names.

    In order to be made into a printed manual and an Info file, a
Texinfo file must begin with lines like this:

        \input texinfo
        @setfilename info-file-name
        @settitle name-of-manual

The contents of the file follow this beginning, and then you must end a
Texinfo file with a line like this:

        @bye

The \input texinfo line tells TeX to use the texinfo.tex file, which
tells TeX how to translate the Texinfo @-commands into TeX typesetting
commands. (Note the use of the backslash, \ ; this is correct for
TeX.) The @setfilename line provides a name for the Info file and the
 @settitle line specifies a title for the page headers (or footers) of
the printed manual.

    The @bye line at the end of the file on a line of its own tells the
formatters that the file is ended and to stop formatting.

    Usually, you will not use quite such a spare format, but will include
mode setting and start-of-header and end-of-header lines at the
beginning of a Texinfo file, like this:

        \input texinfo   @c -*-texinfo-*-
        @c %**start of header
        @setfilename info-file-name
        @settitle name-of-manual
        @c %**end of header

In the first line, -*-texinfo-*- causes Emacs to switch into Texinfo
mode when you edit the file.

    The @c lines which surround the @setfilename and @settitle lines
are optional, but you need them in order to run TeX or Info on just
part of the file. (See
                  Start of Header
                  , for more information.)

    Furthermore, you will usually provide a Texinfo file with a title
page, indices, and the like. But the minimum, which can be useful for
short documents, is just the three lines at the beginning and the one
line at the end.

1.11   texi.info/Six Parts

```
Six Parts of a Texinfo File
===========================
```

   Generally, a Texinfo file contains more than the minimal beginning
and end--it usually contains six parts:

1. Header
     The Header names the file, tells TeX which definitions' file to
     use, and performs other "housekeeping" tasks.

2. Summary Description and Copyright
     The Summary Description and Copyright segment describes the
     document and contains the copyright notice and copying permissions
     for the Info file. The segment must be enclosed between @ifinfo
     and @end ifinfo commands so that the formatters place it only in
     the Info file.

3. Title and Copyright
     The Title and Copyright segment contains the title and copyright
     pages and copying permissions for the printed manual. The segment
     must be enclosed between @titlepage and @end titlepage commands.
     The title and copyright page appear only in the printed manual.

4. 'Top' Node and Master Menu
     The Master Menu contains a complete menu of all the nodes in the
     whole Info file. It appears only in the Info file, in the 'Top'
     node.

5. Body
     The Body of the document may be structured like a traditional book
     or encyclopedia or it may be free form.

6. End
     The End contains commands for printing indices and generating the
     table of contents, and the @bye command on a line of its own.

1.12   texi.info/Short Sample

```
                A Short Sample Texinfo File
===========================
```

   Here is a complete but very short Texinfo file, in 6 parts. The
first three parts of the file, from \input texinfo through to @end
titlepage, look more intimidating than they are. Most of the material
is standard boilerplate; when you write a manual, simply insert the
names for your own manual in this segment. (See
                Beginning a File
                .)

In the following, the sample text is indented; comments on it are not.
The complete file, without any comments, is shown in

                Sample Texinfo File

.

```
Part 1: Header
--------------

The header does not appear in either the Info file or the
printed output.  It sets various parameters, including the
name of the Info file and the title used in the header.

     \input texinfo   @c -*-texinfo-*-
     @c %**start of header
     @setfilename sample.info
     @settitle Sample Document
     @c %**end of header

     @setchapternewpage odd

Part 2: Summary Description and Copyright
-----------------------------------------

The summary description and copyright segment does not
appear in the printed document.

     @ifinfo
     This is a short example of a complete Texinfo file.

     Copyright @copyright{} 1990 Free Software Foundation, Inc.
     @end ifinfo

Part 3: Titlepage and Copyright
-------------------------------

The titlepage segment does not appear in the Info file.

     @titlepage
     @sp 10
     @comment The title is printed in a large font.
     @center @titlefont{Sample Title}

     @c The following two commands start the copyright page.
     @page
     @vskip 0pt plus 1filll
     Copyright @copyright{} 1990 Free Software Foundation, Inc.
     @end titlepage

Part 4: 'Top' Node and Master Menu
----------------------------------

The 'Top' node contains the master menu for the Info file.
Since a printed manual uses a table of contents rather than
a menu, the master menu appears only in the Info file.

     @node    Top,       First Chapter, (dir),    (dir)
     @comment node-name, next,          previous, up

     @menu
     * First Chapter::    The first chapter is the
```

```
                          only chapter in this sample.
     * Concept Index::    This index has two entries.
     @end menu

Part 5:  The Body of the Document
---------------------------------

The body segment contains all the text of the document, but not the
indices or table of contents.  This example illustrates a node and a
chapter containing an enumerated list.

     @node    First Chapter, Concept Index, Top,     Top
     @comment node-name,    next,          previous, up
     @chapter First Chapter
     @cindex Sample index entry

     This is the contents of the first chapter.
     @cindex Another sample index entry

     Here is a numbered list.

     @enumerate
     @item
     This is the first item.

     @item
     This is the second item.
     @end enumerate

     The @code{makeinfo} and @code{texinfo-format-buffer}
     commands transform a Texinfo file such as this into
     an Info file; and @TeX{} typesets it for a printed
     manual.

Part 6: The End of the Document
-------------------------------

The end segment contains commands both for generating an index in a node
and unnumbered chapter of its own and for generating the table of
contents; and it contains the  @bye command that marks the end of the
document.

     @node    Concept Index,    , First Chapter, Top
     @comment node-name,    next, previous,      up
     @unnumbered Concept Index

     @printindex cp

     @contents
     @bye

The Results
-----------

   Here is what the contents of the first chapter of the sample look
like:
```

```
   This is the contents of the first chapter.

   Here is a numbered list.

      1. This is the first item.

      2. This is the second item.

   The makeinfo and texinfo-format-buffer commands transform a
   Texinfo file such as this into an Info file; and TeX typesets it
   for a printed manual.
```

1.13   texi.info/Acknowledgements

```
Acknowledgements
================
```

   Richard M. Stallman wrote Edition 1.0 of this manual.
Robert J. Chassell revised and extended it, starting with Edition 1.1.

   Our thanks go out to all who helped improve this work, particularly
to Francois Pinard and David D. Zuhn, who tirelessly recorded and
reported mistakes and obscurities; our special thanks go to
Melissa Weisshaus for her frequent and often tedious reviews of nearly
similar editions. Our mistakes are our own.

1.14   texi.info/Texinfo Mode

```
                  Using Texinfo Mode
******************
```

   You may edit a Texinfo file with any text editor you choose. A
Texinfo file is no different from any other ASCII file. However, GNU
Emacs comes with a special mode, called Texinfo mode, that provides
Emacs commands and tools to help ease your work.

   This chapter describes features of GNU Emacs' Texinfo mode but not
any features of the Texinfo formatting language. If you are reading
this manual straight through from the beginning, you may want to skim
through this chapter briefly and come back to it after reading
succeeding chapters which describe the Texinfo formatting language in
detail.

```
                  Texinfo Mode Overview
                        How Texinfo mode can help you.

                  Emacs Editing
```

1.15   texi.info/Texinfo Mode Overview

```
Texinfo Mode Overview
=====================
```

Texinfo mode provides special features for working with Texinfo
files:

   * Insert frequently used @commands.

   * Automatically create @node lines.

   * Show the structure of a Texinfo source file.

   * Automatically create or update the 'Next',
     'Previous', and 'Up' pointers of a node.

   * Automatically create or update menus.

   * Automatically create a master menu.

   * Format a part or all of a file for Info.

   * Typeset and print part or all of a file.

   Perhaps the two most helpful features are those for inserting
frequently used @-commands and for creating node pointers and menus.

1.16 texi.info/Emacs Editing

```
The Usual GNU Emacs Editing Commands
====================================
```

   In most cases, the usual Text mode commands work the same in Texinfo
mode as they do in Text mode. Texinfo mode adds new editing commands
and tools to GNU Emacs' general purpose editing features. The major
difference concerns filling. In Texinfo mode, the paragraph separation
variable and syntax table are redefined so that Texinfo commands that
should be on lines of their own are not inadvertently included in
paragraphs. Thus, the M-q (fill-paragraph) command will refill a
paragraph but not mix an indexing command on a line adjacent to it into
the paragraph.

   In addition, Texinfo mode sets the page-delimiter variable to the
value of texinfo-chapter-level-regexp; by default, this is a regular
expression matching the commands for chapters and their equivalents,
such as appendices. With this value for the page delimiter, you can
jump from chapter title to chapter title with the C-x] (forward-page)
and C-x [(backward-page) commands and narrow to a chapter with the C-x
p (narrow-to-page) command. (See Pages, for details about the page
commands.)

   You may name a Texinfo file however you wish, but the convention is
to end a Texinfo file name with one of the three extensions .texinfo,
.texi, or .tex. A longer extension is preferred, since it is explicit,
but a shorter extension may be necessary for operating systems that
limit the length of file names. GNU Emacs automatically enters Texinfo
mode when you visit a file with a .texinfo or .texi extension. Also,
Emacs switches to Texinfo mode when you visit a file that has
-*-texinfo-*- in its first line. If ever you are in another mode and
wish to switch to Texinfo mode, type M-x texinfo-mode.

   Like all other Emacs features, you can customize or enhance Texinfo
mode as you wish. In particular, the keybindings are very easy to
change. The keybindings described here are the default or standard
ones.

1.17 texi.info/Inserting

```
              Inserting Frequently Used Commands
==================================
```

   Texinfo mode provides commands to insert various frequently used
keystrokes.

   The insert commands are invoked by typing C-c twice and then the
first letter of the @-command:

```
C-c C-c c
M-x texinfo-insert-@code
     Insert  @code{} and put the cursor between the braces.
```

```
C-c C-c d
M-x texinfo-insert-@dfn
     Insert  @dfn{} and put the cursor between the braces.

C-c C-c e
M-x texinfo-insert-@end
     Insert  @end and attempt to insert the correct following word,
     such as example or table.  (This command does not handle nested
     lists correctly, but inserts the word appropriate to the
     immediately preceding list.)

C-c C-c i
M-x texinfo-insert-@item
     Insert  @item and put the cursor at the beginning of the next line.

C-c C-c k
M-x texinfo-insert-@kbd
     Insert  @kbd{} and put the cursor between the braces.

C-c C-c n
M-x texinfo-insert-@node
     Insert  @node and a comment line listing the sequence for the
     'Next', 'Previous', and 'Up' nodes.  Leave point after the  @node.

C-c C-c o
M-x texinfo-insert-@noindent
     Insert  @noindent and put the cursor at the beginning of the next
     line.

C-c C-c s
M-x texinfo-insert-@samp
     Insert  @samp{} and put the cursor between the braces.

C-c C-c t
M-x texinfo-insert-@table
     Insert  @table followed by a SPC and leave the cursor after the
     SPC.

C-c C-c v
M-x texinfo-insert-@var
     Insert  @var{} and put the cursor between the braces.

C-c C-c x
M-x texinfo-insert-@example
     Insert  @example and put the cursor at the beginning of the next
     line.

C-c C-c {
M-x texinfo-insert-braces
     Insert {} and put the cursor between the braces.

C-c C-c }
C-c C-c ]
M-x up-list
     Move from between a pair of braces forward past the closing brace.
     Typing C-c C-c ] is easier than typing C-c C-c }, which is,
```

   however, more mnemonic; hence the two keybindings. (Also, you can
   move out from between braces by typing C-f.)

   To put a command such as @code{...} around an existing word,
position the cursor in front of the word and type C-u 1 C-c C-c c.
This makes it easy to edit existing plain text. The value of the
prefix argument tells Emacs how many words following point to include
between braces--1 for one word, 2 for two words, and so on. Use a
negative argument to enclose the previous word or words. If you do not
specify a prefix argument, Emacs inserts the @-command string and
positions the cursor between the braces. This feature works only for
those @-commands that operate on a word or words within one line, such
as @kbd and @var.

   This set of insert commands was created after analyzing the frequency
with which different @-commands are used in the 'GNU Emacs Manual' and
the 'GDB Manual'. If you wish to add your own insert commands, you can
bind a keyboard macro to a key, use abbreviations, or extend the code
in texinfo.el.

   C-c C-c C-d (texinfo-start-menu-description) is an insert command
that works differently from the other insert commands. It inserts a
node's section or chapter title in the space for the description in a
menu entry line. (A menu entry has three parts, the entry name, the
node name, and the description. Only the node name is required, but a
description helps explain what the node is about. See

                The Parts of a Menu
                .)

   To use texinfo-start-menu-description, position point in a menu
entry line and type C-c C-c C-d. The command looks for and copies the
title that goes with the node name, and inserts the title as a
description; it positions point at beginning of the inserted text so you
can edit it. The function does not insert the title if the menu entry
line already contains a description.

   This command is only an aid to writing descriptions; it does not do
the whole job. You must edit the inserted text since a title tends to
use the same words as a node name but a useful description uses
different words.

1.18   texi.info/Showing the Structure

Showing the Section Structure of a File
=======================================

   You can show the section structure of a Texinfo file by using the
C-c C-s command (texinfo-show-structure). This command shows the
section structure of a Texinfo file by listing the lines that begin
with the @-commands for @chapter, @section, and the like. It
constructs what amounts to a table of contents. These lines are
displayed in another buffer called the *Occur* buffer. In that buffer,

you can position the cursor over one of the lines and use the C-c C-c
command (occur-mode-goto-occurrence), to jump to the corresponding spot
in the Texinfo file.

```
C-c C-s
M-x texinfo-show-structure
     Show the  @chapter,  @section, and such lines of a Texinfo file.

C-c C-c
M-x occur-mode-goto-occurrence
     Go to the line in the Texinfo file corresponding to the line under
     the cursor in the *Occur* buffer.
```

   If you call texinfo-show-structure with a prefix argument by typing
C-u C-c C-s, it will list not only those lines with the @-commands for
how the texinfo-show-structure command worked without an argument in
the first version of Texinfo. It was changed because @node lines
clutter up the *Occur* buffer and are usually not needed.) You can use
texinfo-show-structure with a prefix argument to check whether the
'Next', 'Previous', and 'Up' pointers of an @node line are correct.

   Often, when you are working on a manual, you will be interested only
in the structure of the current chapter. In this case, you can mark
off the region of the buffer that you are interested in with the C-x n
(narrow-to-region) command and texinfo-show-structure will work on
only that region. To see the whole buffer again, use C-x w (widen).
(See Narrowing, for more information about the narrowing commands.)

   In addition to providing the texinfo-show-structure command, Texinfo
mode sets the value of the page delimiter variable to match the
chapter-level @-commands. This enables you to use the C-x]
(forward-page) and C-x [(backward-page) commands to move forward
and backward by chapter, and to use the C-x p (narrow-to-page) command
to narrow to a chapter. See Pages, for more information about the page
commands.

1.19   texi.info/Updating Nodes and Menus

```
                    Updating Nodes and Menus
========================
```

   Texinfo mode provides commands for automatically creating or updating
menus and node pointers. The commands are called "update" commands
because their most frequent use is for updating a Texinfo file after
you have worked on it; but you can use them to insert the 'Next',
'Previous', and 'Up' pointers into an @node line that has none and to
create menus in a file that has none.

   If you do not use the updating commands, you need to write menus and
node pointers by hand, which is a tedious task.

```
                    Updating Commands
```

                         Five major updating commands.

                Updating Requirements
                       How to structure a Texinfo file for
                               using the updating command.

                Other Updating Commands
                       How to indent descriptions, insert
                               missing nodes lines, and update
                               nodes in sequence.

1.20 texi.info/Updating Commands

                    The Updating Commands

    You can use the updating commands

    * to insert or update the 'Next', 'Previous', and 'Up' pointers of a
      node,

    * to insert or update the menu for a section, and

    * to create a master menu for a Texinfo source file.

    You can also use the commands to update all the nodes and menus in a
region or in a whole Texinfo file.

    The updating commands work only with conventional Texinfo files,
which are structured hierarchically like books. In such files, a
structuring command line must follow closely after each @node line,
except for the 'Top' @node line. (A structuring command line is a
line beginning with @chapter, @section, or other similar command.)

    You can write the structuring command line on the line that follows
immediately after an @node line or else on the line that follows after
a single @comment line or a single @ifinfo line. You cannot
interpose more than one line between the @node line and the
structuring command line; and you may interpose only an @comment line
or an @ifinfo line.

    Commands which work on a whole buffer require that the 'Top' node be
followed by a node with an @chapter or equivalent-level command. Note
that the menu updating commands will not create a main or master menu
for a Texinfo file that has only @chapter-level nodes! The menu
updating commands only create menus within nodes for lower level nodes.
To create a menu of chapters, you must provide a 'Top' node.

    The menu updating commands remove menu entries that refer to other
Info files since they do not refer to nodes within the current buffer.
This is a deficiency. Rather than use menu entries, you can use cross
references to refer to other Info files. None of the updating commands
affect cross references.

Texinfo mode has five updating commands that are used most often: two
are for updating the node pointers or menu of a single node (or a
region); two are for updating every node pointer and menu in a file;
and one, the texinfo-master-menu command, is for creating a master menu
for a complete file, and optionally, for updating every node and menu
in the whole Texinfo file.

The texinfo-master-menu command is the primary command:

C-c C-u m
M-x texinfo-master-menu
     Create or update a master menu that includes all the other menus
     (incorporating the descriptions from pre-existing menus, if any).

     With an argument (prefix argument, C-u, if interactive), first
     create or update all the nodes and all the regular menus in the
     buffer before constructing the master menu. (See

               The Top Node and Master Menu
               , for more about a master menu.)

     For texinfo-master-menu to work, the Texinfo file must have a
     'Top' node and at least one subsequent node.

     After extensively editing a Texinfo file, you can type the
     following:

          C-u M-x texinfo-master-menu
     or
          C-u C-c C-u m

     This updates all the nodes and menus completely and all at once.

   The other major updating commands do smaller jobs and are designed
for the person who updates nodes and menus as he or she writes a
Texinfo file.

   The commands are:

C-c C-u C-n
M-x texinfo-update-node
     Insert the 'Next', 'Previous', and 'Up' pointers for the node that
     point is within (i.e., for the @node line preceding point). If
     the @node line has pre-existing 'Next', 'Previous', or 'Up'
     pointers in it, the old pointers are removed and new ones inserted.
     With an argument (prefix argument, C-u, if interactive), this
     command updates all @node lines in the region (which is the text
     between point and mark).

C-c C-u C-m
M-x texinfo-make-menu
     Create or update the menu in the node that point is within. With
     an argument (C-u as prefix argument, if interactive), the command
     makes or updates menus for the nodes which are either within or a
     part of the region.

     Whenever texinfo-make-menu updates an existing menu, the
     descriptions from that menu are incorporated into the new menu.
     This is done by copying descriptions from the existing menu to the
     entries in the new menu that have the same node names. If the
     node names are different, the descriptions are not copied to the
     new menu.

C-c C-u C-e
M-x texinfo-every-node-update
     Insert or update the 'Next', 'Previous', and 'Up' pointers for
     every node in the buffer.

C-c C-u C-a
M-x texinfo-all-menus-update
     Create or update all the menus in the buffer. With an argument
     (C-u as prefix argument, if interactive), first insert or
     update all the node pointers before working on the menus.

     If a master menu exists, the texinfo-all-menus-update command
     updates it; but the command does not create a new master menu if
     none already exists. (Use the texinfo-master-menu command for
     that.)

     When working on a document that does not merit a master menu, you
     can type the following:

          C-u C-c C-u C-a
     or
          C-u M-x texinfo-all-menus-update

     This updates all the nodes and menus.

   The texinfo-column-for-description variable specifies the column to
which menu descriptions are indented. By default, the value is 32
although it is often useful to reduce it to as low as 24. You can set
the variable with the M-x edit-options command (see
Editing Variable Values) or with the M-x set-variable command (see
Examining and Setting Variables).

   Also, the texinfo-indent-menu-description command may be used to
indent existing menu descriptions to a specified column. Finally, if
you wish, you can use the texinfo-insert-node-lines command to insert
missing @node lines into a file. (See
                Other Updating Commands
                , for
more information.)

1.21   texi.info/Updating Requirements

                Updating Requirements

   To use the updating commands, you must organize the Texinfo file

hierarchically with chapters, sections, subsections, and the like.
When you construct the hierarchy of the manual, do not 'jump down' more
than one level at a time: you can follow the 'Top' node with a chapter,
but not with a section; you can follow a chapter with a section, but
not with a subsection. However, you may 'jump up' any number of levels
at one time--for example, from a subsection to a chapter.

   Each @node line, with the exception of the line for the 'Top' node,
must be followed by a line with a structuring command such as
   Each @node line/structuring-command line combination must look
either like this:

     @node   Comments, Minimum, Conventions, Overview
     @comment node-name, next,   previous,   up
     @section Comments

   or like this (without the @comment line):

     @node Comments, Minimum, Conventions, Overview
     @section Comments

In this example, 'Comments' is the name of both the node and the
section. The next node is called 'Minimum' and the previous node is
called 'Conventions'. The 'Comments' section is within the 'Overview'
node, which is specified by the 'Up' pointer. (Instead of an @comment
line, you can write an @ifinfo line.)

   If a file has a 'Top' node, it must be called top or Top and be the
first node in the file.

   The menu updating commands create a menu of sections within a
chapter, a menu of subsections within a section, and so on. This means
that you must have a 'Top' node if you want a menu of chapters.

   Incidentally, the makeinfo command will create an Info file for a
hierarchically organized Texinfo file that lacks 'Next', 'Previous' and
'Up' pointers. Thus, if you can be sure that your Texinfo file will be
formatted with makeinfo, you have no need for the 'update node'
commands. (See
                Creating an Info File
                , for more information about
makeinfo.) However, both makeinfo and the texinfo-format-... commands
require that you insert menus in the file.

1.22   texi.info/Other Updating Commands

                Other Updating Commands

   In addition to the five major updating commands, Texinfo mode
possesses several less frequently used updating commands:

M-x texinfo-insert-node-lines

Insert @node lines before the @chapter, @section, and other
sectioning commands wherever they are missing throughout a region
in a Texinfo file.

With an argument (C-u as prefix argument, if interactive), the
texinfo-insert-node-lines command not only inserts @node lines
but also inserts the chapter or section titles as the names of the
corresponding nodes. In addition, it inserts the titles as node
names in pre-existing @node lines that lack names. Since node
names should be more concise than section or chapter titles, you
must manually edit node names so inserted.

For example, the following marks a whole buffer as a region and
inserts @node lines and titles throughout:

     C-x h C-u M-x texinfo-insert-node-lines

(Note that this command inserts titles as node names in @node
lines; the texinfo-start-menu-description command (see

          Inserting Frequently Used Commands
) inserts titles as descriptions
in menu entries, a different action. However, in both cases, you
need to edit the inserted text.)

M-x texinfo-multiple-files-update
     Update nodes and menus in a document built from several separate
     files. With C-u as a prefix argument, create and insert a master
     menu in the outer file. With a numeric prefix argument, such as
     C-u 2, first update all the menus and all the 'Next', 'Previous',
     and 'Up' pointers of all the included files before creating and
     inserting a master menu in the outer file. The
     texinfo-multiple-files-update command is described in the appendix
     on @include files. See
               texinfo-multiple-files-update
               .

M-x texinfo-indent-menu-description
     Indent every description in the menu following point to the
     specified column. You can use this command to give yourself more
     space for descriptions. With an argument (C-u as prefix argument,
     if interactive), the texinfo-indent-menu-description command
     indents every description in every menu in the region. However,
     this command does not indent the second and subsequent lines of a
     multi-line description.

M-x texinfo-sequential-node-update
     Insert the names of the nodes immediately following and preceding
     the current node as the 'Next' or 'Previous' pointers regardless
     of those nodes' hierarchical level. This means that the 'Next'
     node of a subsection may well be the next chapter. Sequentially
     ordered nodes are useful for novels and other documents that you
     read through sequentially. (However, in Info, the g* RET command
     lets you look through the file sequentially, so sequentially
     ordered nodes are not strictly necessary.) With an argument
     (prefix argument, if interactive), the
     texinfo-sequential-node-update command sequentially updates all

        the nodes in the region.

1.23 texi.info/Info Formatting

                Formatting for Info
==================

   Texinfo mode provides several commands for formatting part or all of
a Texinfo file for Info. Often, when you are writing a document, you
want to format only part of a file--that is, a region.

   You can use either the texinfo-format-region or the makeinfo-region
command to format a region:

C-c C-e C-r
M-x texinfo-format-region
C-c C-m C-r
M-x makeinfo-region
     Format the current region for Info.

   You can use either the texinfo-format-buffer or the makeinfo-buffer
command to format a whole buffer:

C-c C-e C-b
M-x texinfo-format-buffer
C-c C-m C-b
M-x makeinfo-buffer
     Format the current buffer for Info.

   For example, after writing a Texinfo file, you can type the
following:

     C-u C-c C-u m
or
     C-u M-x texinfo-master-menu

This updates all the nodes and menus. Then type the following to create
an Info file:

     C-c C-m C-b
or
     M-x makeinfo-buffer

   For the Info formatting commands to work, the file must include a
line that has @setfilename in its header.

   Not all systems support the makeinfo-based formatting commands.

   See
                Create an Info File
                , for details about Info formatting.

1.24   texi.info/Printing

                    Formatting and Printing
========================

    Typesetting and printing a Texinfo file is a multi-step process in
which you first create a file for printing (called a DVI file), and then
print the file. Optionally, you may also create indices. To do this,
you must run the texindex command after first running the tex
typesetting command; and then you must run the tex command again.

    Often, when you are writing a document, you want to typeset and print
only part of a file to see what it will look like. You can use the
texinfo-tex-region and related commands for this purpose. Use the
texinfo-tex-buffer command to format all of a buffer.

C-c C-t C-r
M-x texinfo-tex-region
     Run TeX on the region.

C-c C-t C-b
M-x texinfo-tex-buffer
     Run TeX on the buffer.

C-c C-t C-i
M-x texinfo-texindex
     Run texindex to sort the indices of a Texinfo file formatted with
     texinfo-tex-region or texinfo-tex-buffer. You must run the tex
     command a second time after sorting the raw index files.

C-c C-t C-p
M-x texinfo-tex-print
     Print the file (or the part of the file) previously formatted with
     texinfo-tex-buffer or texinfo-tex-region.

   For texinfo-tex-region or texinfo-tex-buffer to work, the file must
start with a \input texinfo line and must include an @settitle line.
The file must end with @bye on a line by itself. (When you use
texinfo-tex-region, you must surround the @settitle line with
start-of-header and end-of-header lines.)

    See
              Format-Print Hardcopy
              , for a description of the other TeX related
commands, such as tex-show-print-queue.

1.25   texi.info/Texinfo Mode Summary

Texinfo Mode Summary
====================

   In Texinfo mode, each set of commands has default keybindings that
begin with the same keys. All the commands that are custom-created for
Texinfo mode begin with C-c. The keys are somewhat mnemonic.

Insert Commands

   The insert commands are invoked by typing C-c twice and then the
first letter of the @-command to be inserted. (It might make more
sense mnemonically to use C-c C-i, for 'custom insert', but C-c C-c is
quick to type.)

     C-c C-c c   Insert @code.
     C-c C-c d   Insert @dfn.
     C-c C-c e   Insert @end.
     C-c C-c i   Insert @item.
     C-c C-c n   Insert @node.
     C-c C-c s   Insert @samp.
     C-c C-c v   Insert @var.
     C-c C-c {   Insert braces.
     C-c C-c]
     C-c C-c }   Move out of enclosing braces.

     C-c C-c C-d   Insert a node's section title
                      in the space for the description
                      in a menu entry line.

Show Structure

   The texinfo-show-structure command is often used within a narrowed
region.

     C-c C-s   List all the headings.

The Master Update Command

   The texinfo-master-menu command creates a master menu; and can be
used to update every node and menu in a file as well.

     C-c C-u m
     M-x texinfo-master-menu
                      Create or update a master menu.

     C-u C-c C-u m   With C-u as a prefix argument, first
                      create or update all nodes and regular
                      menus, and then create a master menu.

Update Pointers

   The update pointer commands are invoked by typing C-c C-u and then

either typing C-n for texinfo-update-node or typing C-e for
texinfo-every-node-update.

```
    C-c C-u C-n      Update a node.
    C-c C-u C-e      Update every node in the buffer.
```

Update Menus

   Invoke the update menu commands by typing C-c C-u and then either
C-m for texinfo-make-menu or C-a for texinfo-all-menus-update. To
update both nodes and menus at the same time, precede C-c C-u C-a with
C-u.

```
    C-c C-u C-m      Make or update a menu.

    C-c C-u C-a      Make or update all
                     menus in a buffer.

    C-u C-c C-u C-a  With C-u as a prefix argument,
                     first create or update all nodes and
                     then create or update all menus.
```

Format for Info

   The Info formatting commands that are written in Emacs Lisp are
invoked by typing C-c C-e and then either C-r for a region or C-b for
the whole buffer.

   The Info formatting commands that are written in C and based on the
makeinfo program are invoked by typing C-c C-m and then either C-r for
a region or C-b for the whole buffer.

Use the texinfo-format... commands:

```
    C-c C-e C-r      Format the region.
    C-c C-e C-b      Format the buffer.
```

Use makeinfo:

```
    C-c C-m C-r      Format the region.
    C-c C-m C-b      Format the buffer.
    C-c C-m C-l      Recenter the makeinfo output buffer.
    C-c C-m C-k      Kill the makeinfo formatting job.
```

Typeset and Print

   The TeX typesetting and printing commands are invoked by typing C-c
C-t and then another control command: C-r for texinfo-tex-region, C-b
for texinfo-tex-buffer, and so on.

```
    C-c C-t C-r      Run TeX on the region.
    C-c C-t C-b      Run TeX on the buffer.
    C-c C-t C-i      Run texindex.
    C-c C-t C-p      Print the DVI file.
```

```
     C-c C-t C-q      Show the print queue.
     C-c C-t C-d      Delete a job from the print queue.
     C-c C-t C-k      Kill the current TeX formatting job.
     C-c C-t C-x      Quit a currently stopped TeX formatting job.
     C-c C-t C-l      Recenter the output buffer.

Other Updating Commands
-----------------------

   The 'other updating commands' do not have standard keybindings
because they are rarely used.

     M-x texinfo-insert-node-lines
                    Insert missing  @node lines in region.
                    With C-u as a prefix argument,
                    use section titles as node names.

     M-x texinfo-multiple-files-update
                    Update a multi-file document.
                    With C-u 2 as a prefix argument,
                    create or update all nodes and menus
                    in all included files first.

     M-x texinfo-indent-menu-description
                    Indent descriptions.

     M-x texinfo-sequential-node-update
                    Insert node pointers in strict sequence.
```

1.26   texi.info/Beginning a File

```
                 Beginning a Texinfo File
***********************

   Certain pieces of information must be provided at the beginning of a
Texinfo file, such as the name of the file and the title of the
document.
```

```
             Four Parts
                              Four parts begin a Texinfo file.

             Sample Beginning
                     Here is a sample beginning for a Texinfo file.

             Header
                              The very beginning of a Texinfo file.

             Info Summary and Permissions
               Summary and copying permissions for Info.

             Titlepage & Copyright Page
               Creating the title and copyright pages.
```

              The Top Node
                                   Creating the 'Top' node and master menu.

           Software Copying Permissions
             Ensure that you and others continue to
                                 have the right to use and share software.

1.27   texi.info/Four Parts

Four Parts Begin a File
=======================

   Generally, the beginning of a Texinfo file has four parts:

  1. The header, delimited by special comment lines, that includes the
     commands for naming the Texinfo file and telling TeX what
     definitions' file to use when processing the Texinfo file.

  2. A short statement of what the file is about, with a copyright
     notice and copying permissions. This is enclosed in @ifinfo and
     @end ifinfo commands so that the formatters place it only in the
     Info file.

  3. A title page and copyright page, with a copyright notice and
     copying permissions. This is enclosed between @titlepage and
     @end titlepage commands. The title and copyright page appear only
     in the printed manual.

  4. The 'Top' node that contains a menu for the whole Info file. The
     contents of this node appear only in the Info file.

     Also, optionally, you may include the copying conditions for a
program and a warranty disclaimer. The copying section will be
followed by an introduction or else by the first chapter of the manual.

     Since the copyright notice and copying permissions for the Texinfo
document (in contrast to the copying permissions for a program) are in
parts that appear only in the Info file or only in the printed manual,
this information must be given twice.

1.28   texi.info/Sample Beginning

Sample Texinfo File Beginning
=============================

   The following sample shows what is needed.

     \input texinfo   @c -*-texinfo-*-

```
@c %**start of header
@setfilename name-of-info-file
@settitle name-of-manual
@setchapternewpage odd
@c %**end of header

@ifinfo
This file documents ...

Copyright year copyright-owner

Permission is granted to ...
@end ifinfo

@c  This title page illustrates only one of the
@c  two methods of forming a title page.

@titlepage
@title name-of-manual-when-printed
@subtitle subtitle-if-any
@subtitle second-subtitle
@author author

@c  The following two commands
@c  start the copyright page.
@page
@vskip 0pt plus 1filll
Copyright @copyright{} year copyright-owner

Published by ...

Permission is granted to ...
@end titlepage

@node Top, Overview, (dir), (dir)

@ifinfo
This document describes ...

This document applies to version ...
of the program named ...
@end ifinfo

@menu
* Copying::          Your rights and freedoms.
* First Chapter::    Getting started ...
* Second Chapter::               ...
  ...
  ...
@end menu

@node    First Chapter, Second Chapter, top,     top
@comment node-name,      next,             previous, up
@chapter First Chapter
@cindex Index entry for First Chapter
```

1.29   texi.info/Header

```
                 The Texinfo File Header
========================

   Texinfo files start with at least three lines that provide Info and
TeX with necessary information.  These are the \input texinfo line, the
 @settitle line, and the  @setfilename line.  If you want to run TeX on
just a part of the Texinfo File, you must write the  @settitle and
   Thus, the beginning of a Texinfo file looks like this:

     \input texinfo   @c -*-texinfo-*-
     @setfilename sample.info
     @settitle Sample Document

or else like this:

     \input texinfo   @c -*-texinfo-*-
     @c %**start of header
     @setfilename sample.info
     @settitle Sample Document
     @c %**end of header
```

```
                 First Line
                                 The first line of a Texinfo file.

                 Start of Header
                           Formatting a region requires this.

                 setfilename
                                 Tell Info the name of the Info file.

                 settitle
                                  Create a title for the printed work.

                 setchapternewpage
                         Start chapters on right-hand pages.

                 paragraphindent
                               An option to specify paragraph indentation.

                 End of Header
                            Formatting a region requires this.
```

1.30   texi.info/First Line

```
The First Line of a Texinfo File
--------------------------------

   Every Texinfo file that is to be the top-level input to TeX must
```

begin with a line that looks like this:

```
\input texinfo   @c -*-texinfo-*-
```

This line serves two functions:

1. When the file is processed by TeX, the \input texinfo command
   tells TeX to load the macros needed for processing a Texinfo file.
   These are in a file called texinfo.tex, which is usually located
   in the /usr/lib/tex/macros directory. TeX uses the backslash, \ ,
   to mark the beginning of a command, just as Texinfo uses @. The
   texinfo.tex file causes the switch from \ to @; before the
   switch occurs, TeX requires \ , which is why it appears at the
   beginning of the file.

2. When the file is edited in GNU Emacs, the -*-texinfo-*- mode
   specification tells Emacs to use Texinfo mode.

1.31   texi.info/Start of Header

```
Start of Header
---------------
```

   Write a start-of-header line on the second line of a Texinfo file.
Follow the start-of-header line with @setfilename and @settitle lines
and, optionally, with other command lines, such as @smallbook or
   With these lines, you can format part of a Texinfo file for Info or
typeset part for printing.

   A start-of-header line looks like this:

```
@c %**start of header
```

   The odd string of characters, %**, is to ensure that no other
comment is accidentally taken for a start-of-header line.

1.32   texi.info/setfilename

```
              @setfilename
-------------
```

   In order to be made into an Info file, a Texinfo file must contain a
line that looks like this:

```
@setfilename info-file-name
```

   Write the @setfilename command at the beginning of a line and
follow it on the same line by the Info file name. Do not write
anything else on the line; anything on the line after the command is
considered part of the file name, including a comment.

   The @setfilename line specifies the name of the Info file to be
generated. This name should be different from the name of the Texinfo
file. The convention is to write a name with a .info extension, to
produce an Info file name such as texinfo.info.

   Some operating systems cannot handle long file names. You can run
into a problem even when the file name you specify is itself short
enough. This occurs because the Info formatters split a long Info file
into short indirect subfiles, and name them by appending '-1', '-2',
..., '-10', '-11', and so on, to the original file name. (See

                Tag Files and Split Files
                .) The subfile name texinfo.info-10, for
example, is too long for some systems; so the Info file name for this
document is actually texinfo rather than texinfo.info.

   The Info formatting commands ignore everything written before the
\input line) does not need to be commented out. The @setfilename line
is ignored when you typeset a printed manual.

1.33 texi.info/settitle

                @settitle

   In order to be made into a printed manual, a Texinfo file must
contain a line that looks like this:

     @settitle title

   Write the @settitle command at the beginning of a line and follow
it on the same line by the title. This tells TeX the title to use in a
header or footer. Do not write anything else on the line; anything on
the line after the command is considered part of the title, including a
comment.

   Conventionally, TeX formats a Texinfo file for double-sided output
so as to print the title in the left-hand (even-numbered) page headings
and the current chapter titles in the right-hand (odd-numbered) page
headings. (TeX learns the title of each chapter from each @chapter
command.) Page footers are not printed.

   Even if you are printing in a single-sided style, TeX looks for an
heading.

   The @settitle command should precede everything that generates
actual output in TeX.

   Although the title in the @settitle command is usually the same as
the title on the title page, it does not affect the title as it appears
on the title page. Thus, the two do not need not match exactly; and
the title in the @settitle command can be a shortened or expanded

version of the title as it appears on the title page. (See
                @titlepage
                .)

   TeX prints page headings only for that text that comes after the
for more information.)

   You may, if you wish, create your own, customized headings and
footings. See
                Page Headings
                , for a detailed discussion of this process.

1.34 texi.info/setchapternewpage

                @setchapternewpage

   In a book or a manual, text is usually printed on both sides of the
paper, chapters start on right-hand pages, and right-hand pages have
odd numbers. But in short reports, text often is printed only on one
side of the paper. Also in short reports, chapters sometimes do not
start on new pages, but are printed on the same page as the end of the
preceding chapter, after a small amount of vertical whitespace.

   You can use the @setchapternewpage command with various arguments
to specify how TeX should start chapters and whether it should typeset
pages for printing on one or both sides of the paper (single-sided or
double-sided printing).

   Write the @setchapternewpage command at the beginning of a line
followed by its argument.

   For example, you would write the following to cause each chapter to
start on a fresh odd-numbered page:

    @setchapternewpage odd

  You can specify one of three alternatives with the
 @setchapternewpage off
    Cause TeX to typeset a new chapter on the same page as the last
    chapter, after skipping some vertical whitespace. Also, cause TeX
    to format page headers for single-sided printing. (You can
    override the headers format with the @headings double command; see

                The @headings Command
                .)

 @setchapternewpage on
    Cause TeX to start new chapters on new pages and to typeset page
    headers for single-sided printing. This is the form most often
    used for short reports.

    This alternative is the default.

```
@setchapternewpage odd
     Cause TeX to start new chapters on new, odd-numbered pages
     (right-handed pages) and to typeset for double-sided printing.
     This is the form most often used for books and manuals.
```

Texinfo does not have an @setchapternewpage even command.

(You can countermand or modify an @setchapternewpage command with an
   At the beginning of a manual or book, pages are not numbered--for
example, the title and copyright pages of a book are not numbered. By
convention, table of contents pages are numbered with roman numerals
and not in sequence with the rest of the document.

     Since an Info file does not have pages, the @setchapternewpage
command has no effect on it.

     Usually, you do not write an @setchapternewpage command for
single-sided printing, but accept the default which is to typeset for
single-sided printing and to start new chapters on new pages. Usually,
you write an @setchapternewpage odd command for double-sided printing.

1.35   texi.info/paragraphindent

```
               Paragraph Indenting
------------------
```

   The Info formatting commands may insert spaces at the beginning of
the first line of each paragraph, thereby indenting that paragraph. You
can use the @paragraphindent command to specify the indentation.
Write an @paragraphindent command at the beginning of a line followed
by either asis or a number. The template is:

```
     @paragraphindent indent
```

   The Info formatting commands indent according to the value of indent:

   * If the value of indent is asis, the Info formatting commands do
     not change the existing indentation.

   * If the value of indent is 0, the Info formatting commands delete
     existing indentation.

   * If the value of indent is greater than 0, the Info formatting
     commands indent the paragraph by that number of spaces.

   The default value of indent is asis.

   Write the @paragraphindent command before or shortly after the
end-of-header line at the beginning of a Texinfo file. (If you write
the command between the start-of-header and end-of-header lines, the
region formatting commands indent paragraphs as specified.)

   A peculiarity of texinfo-format-buffer and texinfo-format-region is
that they do not indent (nor fill) paragraphs that contain @w or @*
commands. See
                  Refilling Paragraphs
                  , for a detailed description of what
goes on.

1.36   texi.info/End of Header

End of Header

   Follow the header lines with an end-of-header line. An
end-of-header line looks like this:

     @c %**end of header

   If you include the @setchapternewpage command between the
start-of-header and end-of-header lines, TeX will typeset a region as
that command specifies. Similarly, if you include an @smallbook
command between the start-of-header and end-of-header lines, TeX will
typeset a region in the "small" book format.

   The reason for the odd string of characters (%**) is so that the
texinfo-tex-region command does not accidentally find something that it
should not when it is looking for the header.

   The start-of-header line and the end-of-header line are Texinfo mode
variables that you can change.

1.37   texi.info/Info Summary and Permissions

                  Summary and Copying Permissions for Info
===

   The title page and the copyright page appear only in the printed
copy of the manual; therefore, the same information must be inserted in
a section that appears only in the Info file. This section usually
contains a brief description of the contents of the Info file, a
copyright notice, and copying permissions.

   The copyright notice should read:

     Copyright year copyright-owner

and be put on a line by itself.

   Standard text for the copyright permissions is contained in an
appendix to this manual; see

```
                    ifinfo Copying Permissions
                    , for the
complete text.
```

   The permissions text appears in an Info file before the first node.
This mean that a reader does not see this text when reading the file
using Info, except when using the advanced Info command g *.

1.38   texi.info/Titlepage & Copyright Page

```
                    The Title and Copyright Pages
==============================
```

   A manual's name and author are usually printed on a title page.
Sometimes copyright information is printed on the title page as well;
more often, copyright information is printed on the back of the title
page.

   The title and copyright pages appear in the printed manual, but not
in the Info file. Because of this, it is possible to use several
slightly obscure TeX typesetting commands that cannot be used in an
Info file. In addition, this part of the beginning of a Texinfo file
contains the text of the copying permissions that will appear in the
printed manual.

   See
                    Titlepage Copying Permissions
                    , for the standard text for the
copyright permissions.

```
                titlepage
                                    Create a title for the printed document.

                titlefont center sp
                        The  @titlefont,  @center,
                                and  @sp commands.

                title subtitle author
                        The  @title,  @subtitle,
                                and  @author commands.

                Copyright & Permissions
                        How to write the copyright notice and
                                    include copying permissions.

                end titlepage
                                    Turn on page headings after the title and
                                        copyright pages.

                headings on off
                                An option for turning headings on and off
```

                                    and double or single sided printing.

1.39   texi.info/titlepage

                       @titlepage

   Start the material for the title page and following copyright page
with @titlepage on a line by itself and end it with @end titlepage on
a line by itself.

   The @end titlepage command starts a new page and turns on page
numbering. (See
                    Page Headings
                    , for details about how to generate of
page headings.) All the material that you want to appear on unnumbered
pages should be put between the @titlepage and @end titlepage
commands. By using the @page command you can force a page break
within the region delineated by the @titlepage and @end titlepage
commands and thereby create more than one unnumbered page. This is how
the copyright page is produced. (The @titlepage command might perhaps
have been better named the @titleandadditionalpages command, but that
would have been rather long!)

   When you write a manual about a computer program, you should write
the version of the program to which the manual applies on the title
page. If the manual changes more frequently than the program or is
independent of it, you should also include an edition number(1) for the
manual. This helps readers keep track of which manual is for which
version of the program. (The 'Top' node should also contain this
information; see
                    @top
                    .)

   Texinfo provides two methods for creating a title page. One method
uses the @titlefont, @sp, and @center commands to generate a title
page in which the words on the page are centered.

   The second method uses the @title, @subtitle, and @author
commands to create a title page with black rules under the title and
author lines and the subtitle text set flush to the right hand side of
the page. With this method, you do not specify any of the actual
formatting of the title page. You specify the text you want, and
Texinfo does the formatting. You may use either method.

   ---------- Footnotes ----------

   (1) We have found that it is helpful to refer to versions of
manuals as 'editions' and versions of programs as 'versions';
otherwise, we find we are liable to confuse each other in conversation
by referring to both the documentation and the software with the same
words.

1.40   texi.info/titlefont center sp

                    @titlefont, @center, and @sp

   You can use the @titlefont, @sp, and @center commands to create a
title page for a printed document. (This is the first of the two
methods for creating a title page in Texinfo.)

   Use the @titlefont command to select a large font suitable for the
title itself.

   For example:

     @titlefont{Texinfo}

   Use the @center command at the beginning of a line to center the
remaining text on that line. Thus,

     @center @titlefont{Texinfo}

centers the title, which in this example is "Texinfo" printed in the
title font.

   Use the @sp command to insert vertical space. For example:

     @sp 2

This inserts two blank lines on the printed page. (See
                @sp
                , for more
information about the @sp command.)

   A template for this method looks like this:

     @titlepage
     @sp 10
     @center @titlefont{name-of-manual-when-printed }
     @sp 2
     @center subtitle-if-any
     @sp 2
     @center author
     ...
     @end titlepage

   The spacing of the example fits an 8 1/2 by 11 inch manual.

1.41   texi.info/title subtitle author

 @title, @subtitle, and @author

   You can use the @title, @subtitle, and @author commands to create
a title page in which the vertical and horizontal spacing is done for
you automatically. This contrasts with the method described in the
previous section, in which the @sp command is needed to adjust
vertical spacing.

   Write the @title, @subtitle, or @author commands at the beginning
of a line followed by the title, subtitle, or author.

   The @title command produces a line in which the title is set flush
to the left-hand side of the page in a larger than normal font. The
title is underlined with a black rule.

   The @subtitle command sets subtitles in a normal-sized font flush
to the right-hand side of the page.

   The @author command sets the names of the author or authors in a
middle-sized font flush to the left-hand side of the page on a line
near the bottom of the title page. The names are underlined with a
black rule that is thinner than the rule that underlines the title.
(The black rule only occurs if the @author command line is followed by
an @page command line.)

   There are two ways to use the @author command: you can write the
name or names on the remaining part of the line that starts with an
     @author by Jane Smith and John Doe

or you can write the names one above each other by using two (or more)
     @author Jane Smith
     @author John Doe

(Only the bottom name is underlined with a black rule.)

   A template for this method looks like this:

     @titlepage
     @title name-of-manual-when-printed
     @subtitle subtitle-if-any
     @subtitle second-subtitle
     @author author
     @page
     ...
     @end titlepage

Contrast this form with the form of a title page written using the
     @titlepage
     @sp 10
     @center @titlefont{Name of Manual When Printed}
     @sp 2
     @center Subtitle, If Any
     @sp 1
     @center Second subtitle
     @sp 2

```
    @center Author
    @page
    ...
    @end titlepage
```

1.42   texi.info/Copyright & Permissions

```
              Copyright Page and Permissions
----------------------------
```

   By international treaty, the copyright notice for a book should be
either on the title page or on the back of the title page. The
copyright notice should include the year followed by the name of the
organization or person who owns the copyright.

   When the copyright notice is on the back of the title page, that page
is customarily not numbered. Therefore, in Texinfo, the information on
the copyright page should be within @titlepage and @end titlepage
commands.

   Use the @page command to cause a page break. To push the copyright
notice and the other text on the copyright page towards the bottom of
the page, you can write a somewhat mysterious line after the @page
command that reads like this:

     @vskip 0pt plus 1filll

This is a TeX command that is not supported by the Info formatting
commands. The @vskip command inserts whitespace. The 0pt plus 1filll
means to put in zero points of mandatory whitespace, and as much
optional whitespace as needed to push the following text to the bottom
of the page. Note the use of three ls in the word filll; this is the
correct usage in TeX.

   In a printed manual, the @copyright{} command generates a c inside
a circle. (In Info, it generates (C).) The copyright notice itself
has the following legally defined sequence:

     Copyright (C) year copyright-owner

   It is customary to put information on how to get a manual after the
copyright notice, followed by the copying permissions for the manual.

   Note that permissions must be given here as well as in the summary
segment within @ifinfo and @end ifinfo that immediately follows the
header since this text appears only in the printed manual and the
ifinfo text appears only in the Info file.

   See
              Sample Permissions
              , for the standard text.

1.43 texi.info/end titlepage

               Heading Generation

   An @end titlepage command on a line by itself not only marks the
end of the title and copyright pages, but also causes TeX to start
generating page headings and page numbers.

   To repeat what is said elsewhere, Texinfo has two standard page
heading formats, one for documents which are printed on one side of
each sheet of paper (single-sided printing), and the other for
documents which are printed on both sides of each sheet (double-sided
printing). (See
               @setchapternewpage
               .) You can specify these formats in
different ways:

   * The conventional way is to write an @setchapternewpage command
      before the title page commands, and then have the @end titlepage
      command start generating page headings in the manner desired.
      (See
               @setchapternewpage
               .)

   * Alternatively, you can use the @headings command to prevent page
      headings from being generated or to start them for either single or
      double-sided printing. (Write an @headings command immediately
      after the @end titlepage command. See
               The @headings Command
               , for
      more information.)

   * Or, you may specify your own page heading and footing format. See

               Page Headings
               , for detailed information about page headings and
      footings.

   Most documents are formatted with the standard single-sided or
double-sided format, using @setchapternewpage odd for double-sided
printing and no @setchapternewpage command for single-sided printing.

1.44 texi.info/headings on off

               The @headings Command

   The @headings command is rarely used. It specifies what kind of
page headings and footings to print on each page. Usually, this is
controlled by the @setchapternewpage command. You need the @headings
command only if the @setchapternewpage command does not do what you

want, or if you want to turn off pre-defined page headings prior to
defining your own. Write an @headings command immediately after the
   There are four ways to use the @headings command:

 @headings off
     Turn off printing of page headings.

 @headings single
     Turn on page headings appropriate for single-sided printing.

 @headings double
 @headings on
     Turn on page headings appropriate for double-sided printing. The
     two commands, @headings on and @headings double, are synonymous.

   For example, suppose you write @setchapternewpage off before the
as the end of the last chapter. This command also causes TeX to
typeset page headers for single-sided printing. To cause TeX to
typeset for double sided printing, write @headings double after the
   You can stop TeX from generating any page headings at all by writing
 @headings off on a line of its own immediately after the line
containing the @end titlepage command, like this:

     @end titlepage
     @headings off

The @headings off command overrides the @end titlepage command, which
would otherwise cause TeX to print page headings.

   You can also specify your own style of page heading and footing.
See
               Page Headings
               , for more information.

1.45   texi.info/The Top Node

               The 'Top' Node and Master Menu
===============================

   The 'Top' node is the node from which you enter an Info file.

   A 'Top' node should contain a brief description of the Info file and
an extensive, master menu for the whole Info file. This helps the
reader understand what the Info file is about. Also, you should write
the version number of the program to which the Info file applies; or,
at least, the edition number.

   The contents of the 'Top' node should appear only in the Info file;
none of it should appear in printed output, so enclose it between
you are not required to enclose these parts between @ifinfo and @end
ifinfo, but it is simplest to do so. See
               Conditionally Visible Text
               .)

```
                      Title of Top Node
                            Sketch what the file is about.

                      Master Menu Parts
                            A master menu has three or more parts.
```

1.46   texi.info/Title of Top Node

```
                  'Top' Node Title
----------------
```

   Sometimes, you will want to place an @top sectioning command line
containing the title of the document immediately after the @node Top
line (see

                The @top Sectioning Command
                , for more information).

   For example, the beginning of the Top node of this manual contains an
 @top sectioning command, a short description, and edition and version
information. It looks like this:

```
    ...
    @end titlepage

    @ifinfo
    @node Top, Copying, (dir), (dir)
    @top Texinfo

    Texinfo is a documentation system...

    This is edition...
    ...
    @end ifinfo

    @menu
    * Copying::                 Texinfo is freely
                                  redistributable.
    * Overview::                What is Texinfo?
    ...
    @end menu
```

   In a 'Top' node, the 'Previous', and 'Up' nodes usually refer to the
top level directory of the whole Info system, which is called (dir).
The 'Next' node refers to the first node that follows the main or master
menu, which is usually the copying permissions, introduction, or first
chapter.

1.47   texi.info/Master Menu Parts

                    Parts of a Master Menu

   A master menu is a detailed main menu listing all the nodes in a
file.

   A master menu is enclosed in @menu and @end menu commands and does
not appear in the printed document.

   Generally, a master menu is divided into parts.

   * The first part contains the major nodes in the Texinfo file: the
     nodes for the chapters, chapter-like sections, and the appendices.

   * The second part contains nodes for the indices.

   * The third and subsequent parts contain a listing of the other,
     lower level nodes, often ordered by chapter. This way, rather
     than go through an intermediary menu, an inquirer can go directly
     to a particular node when searching for specific information.
     These menu items are not required; add them if you think they are a
     convenience.

   Each section in the menu can be introduced by a descriptive line. So
long as the line does not begin with an asterisk, it will not be
treated as a menu entry. (See
                Writing a Menu
                , for more information.)

   For example, the master menu for this manual looks like the following
(but has many more entries):

     @menu
     * Copying::   Texinfo is freely
                             redistributable.
     * Overview::   What is Texinfo?
     * Texinfo Mode::   Special features in GNU Emacs.
     ...
     ...
     * Command and Variable Index::
                             An entry for each @-command.
     * Concept Index::   An entry for each concept.

      --- The Detailed Node Listing ---

     Overview of Texinfo

     * Info Files::   What is an Info file?
     * Printed Manuals::   Characteristics of
                             a printed manual.
     ...
     ...

     Using Texinfo Mode

```
   * Info on a Region::     Formatting part of a file
                               for Info.
   ...
   ...
   @end menu
```

1.48 texi.info/Software Copying Permissions

```
               Software Copying Permissions
===============================
```

   If the Texinfo file has a section containing the "General Public
License" and the distribution information and a warranty disclaimer for
the software that is documented, this section usually follows the 'Top'
node. The General Public License is very important to Project GNU
software. It ensures that you and others will continue to have a right
to use and share the software.

   The copying and distribution information and the disclaimer are
followed by an introduction or else by the first chapter of the manual.

   Although an introduction is not a required part of a Texinfo file, it
is very helpful. Ideally, it should state clearly and concisely what
the file is about and who would be interested in reading it. In
general, an introduction would follow the licensing and distribution
information, although sometimes people put it earlier in the document.
Usually, an introduction is put in an @unnumbered section. (See

```
               The @unnumbered and @appendix Commands
               .)
```

1.49 texi.info/Ending a File

```
               Ending a Texinfo File
********************
```

   The end of a Texinfo file should include the commands that create
indices and generate detailed and summary tables of contents. And it
must include the @bye command that marks the last line processed by
TeX.

   For example:

```
   @node    Concept Index,     , Variables Index, Top
   @c         node-name,    next, previous,        up
   @unnumbered Concept Index
```

```
   @printindex cp

   @contents
   @bye
```

1.50   texi.info/Printing Indices & Menus

                 Index Menus and Printing an Index
=================================

   To print an index means to include it as part of a manual or Info
file. This does not happen automatically just because you use @cindex
or other index-entry generating commands in the Texinfo file; those
just cause the raw data for the index to be accumulated. To generate
an index, you must include the @printindex command at the place in the
document where you want the index to appear. Also, as part of the
process of creating a printed manual, you must run a program called
texindex (see
              Format-Print Hardcopy
) to sort the raw data to produce a
sorted index file. The sorted index file is what is actually used to
print the index.

   Texinfo offers six different types of predefined index: the concept
index, the function index, the variables index, the keystroke index, the
program index, and the data type index (see
              Predefined Indices
). Each index type has a two-letter name:
cp, fn, vr, ky, pg, and tp. You may merge indices, or put them into
separate sections (see
              Combining Indices
              ); or you may define your own
indices (see
              Defining New Indices
).

   The @printindex command takes a two-letter index name, reads the
corresponding sorted index file and formats it appropriately into an
index.

   The @printindex command does not generate a chapter heading for the

index. Consequently, you should precede the @printindex command with
a suitable section or chapter command (usually @unnumbered) to supply
the chapter heading and put the index into the table of contents.
Precede the @unnumbered command with an @node line.

   For example:

     @node Variable Index, Concept Index, Function Index, Top
     @comment   node-name,   next,   previous, up
     @unnumbered Variable Index

     @printindex vr

     @node   Concept Index,   , Variable Index, Top
     @comment   node-name, next,   previous, up
     @unnumbered Concept Index

     @printindex cp

     @summarycontents
     @contents
     @bye

(Readers often prefer that the concept index come last in a book, since
that makes it easiest to find.)

1.51 texi.info/Contents

Generating a Table of Contents
==============================

   The @chapter, @section, and other structuring commands supply the
information to make up a table of contents, but they do not cause an
actual table to appear in the manual. To do this, you must use the
 @contents
     Generate a table of contents in a printed manual, including all
     chapters, sections, subsections, etc., as well as appendices and
     unnumbered chapters. (Headings generated by the @heading series
     of commands do not appear in the table of contents.) The
     @contents command should be written on a line by itself.

 @shortcontents
 @summarycontents
     (@summarycontents is a synonym for @shortcontents; the two
     commands are exactly the same.)

     Generate a short or summary table of contents that lists only the
     chapters (and appendices and unnumbered chapters). Omit sections,
     subsections and subsubsections. Only a long manual needs a short
     table of contents in addition to the full table of contents.

     Write the @shortcontents command on a line by itself right before
     the @contents command.

The table of contents commands automatically generate a chapter-like heading at the top of the first table of contents page. Write the table of contents commands at the very end of a Texinfo file, just before the @bye command, following any index sections--anything in the Texinfo file after the table of contents commands will be omitted from the table of contents.

When you print a manual with a table of contents, the table of contents are printed last and numbered with roman numerals. You need to place those pages in their proper place, after the title page, yourself. (This is the only collating you need to do for a printed manual. The table of contents is printed last because it is generated after the rest of the manual is typeset.)

Here is an example of where to write table of contents commands:

```
indices ...
@shortcontents
@contents
@bye
```

Since an Info file uses menus instead of tables of contents, the Info formatting commands ignore the @contents and @shortcontents commands.

1.52   texi.info/File End

                   @bye File Ending
==================

An @bye command terminates TeX or Info formatting. None of the formatting commands see any of the file following @bye. The @bye command should be on a line by itself.

If you wish, you may follow the @bye line with notes. These notes will not be formatted and will not appear in either Info or a printed manual; it is as if text after @bye were within @ignore ... @end ignore. Also, you may follow the @bye line with a local variables list. See
                   Using Local Variables and the Compile Command
                  , for more
information.

1.53   texi.info/Structuring

                   Chapter Structuring
****

The chapter structuring commands divide a document into a hierarchy

of chapters, sections, subsections, and subsubsections. These commands
generate large headings; they also provide information for the table of
contents of a printed manual (see
                  Generating a Table of Contents
).

   The chapter structuring commands do not create an Info node
structure, so normally you should put an @node command immediately
before each chapter structuring command (see
                  Nodes
). The only time you
are likely to use the chapter structuring commands without using the
node structuring commands is if you are writing a document that
contains no cross references and will never be transformed into Info
format.

   It is unlikely that you will ever write a Texinfo file that is
intended only as an Info file and not as a printable document. If you
do, you might still use chapter structuring commands to create a
heading at the top of each node--but you don't need to.

                  Tree Structuring
                          A manual is like an upside down tree ...

                  Structuring Command Types
                     How to divide a manual into parts.

                  makeinfo top
                            The @top command, part of the 'Top' node.

                  chapter

                  unnumbered & appendix

                  majorheading & chapheading

                  section

                  unnumberedsec appendixsec heading

                  subsection

                  unnumberedsubsec appendixsubsec subheading

                  subsubsection
                            Commands for the lowest level sections.

1.54 texi.info/Tree Structuring

                  Tree Structure of Sections
==========================

A Texinfo file is usually structured like a book with chapters,
sections, subsections, and the like. This structure can be visualized
as a tree (or rather as an upside-down tree) with the root at the top
and the levels corresponding to chapters, sections, subsection, and
subsubsections.

Here is a diagram that shows a Texinfo file with three chapters,
each of which has two sections.

```
                        Top
                         |
          ------------------------------------
          |                 |                 |
      Chapter 1         Chapter 2         Chapter 3
          |                 |                 |
      --------          --------          --------
      |      |          |      |          |      |
   Section Section   Section Section   Section Section
     1.1    1.2        2.1    2.2        3.1    3.2
```
In a Texinfo file that has this structure, the beginning of Chapter 2
looks like this:

```
    @node    Chapter 2,  Chapter 3, Chapter 1, top
    @chapter Chapter 2
```

The chapter structuring commands are described in the sections that
follow; the @node and @menu commands are described in following
chapters. (See
                Nodes
                , and see
                Menus
                .)

1.55 texi.info/Structuring Command Types

```
                Types of Structuring Command
============================
```

The chapter structuring commands fall into four groups or series,
each of which contains structuring commands corresponding to the
hierarchical levels of chapters, sections, subsections, and
subsubsections.

The four groups are the @chapter series, the @unnumbered series,
the @appendix series, and the @heading series.

Each command produces titles that have a different appearance on the
printed page or Info file; only some of the commands produce titles
that are listed in the table of contents of a printed book or manual.

   * The @chapter and @appendix series of commands produce numbered

   or lettered entries both in the body of a printed work and in its
   table of contents.

 * The @unnumbered series of commands produce unnumbered entries
   both in the body of a printed work and in its table of contents.
   The @top command, which has a special use, is a member of this
   series (see
               @top
).

 * The @heading series of commands produce unnumbered headings that
   do not appear in a table of contents. The heading commands never
   start a new page.

 * The @majorheading command produces results similar to using the
   @chapheading command but generates a larger vertical whitespace
   before the heading.

 * When an @setchapternewpage command says to do so, the @chapter,
   @unnumbered, and @appendix commands start new pages in the
   printed manual; the @heading commands do not.

   Here are the four groups of chapter structuring commands:

                                                    No new pages
   Numbered   Unnumbered   Lettered and numbered Unnumbered
   In contents   In contents   In contents   Not in contents

                   @top   @majorheading
   @chapter   @unnumbered   @appendix   @chapheading
   @section   @unnumberedsec   @appendixsec   @heading
   @subsection   @unnumberedsubsec   @appendixsubsec @subheading
   @subsubsection @unnumberedsubsubsec @appendixsubsubsec @subsubheading

1.56 texi.info/makeinfo top

                  @top
=====

   The @top command is a special sectioning command that you use only
after an @node Top line at the beginning of a Texinfo file. The @top
command tells the makeinfo formatter which node is the 'Top' node. It
has the same typesetting effect as @unnumbered (see @unnumbered). For
detailed information, see
               The @top Command
                  .

1.57 texi.info/chapter

```
 @chapter
=========
```

   @chapter identifies a chapter in the document. Write the command
at the beginning of a line and follow it on the same line by the title
of the chapter.

   For example, this chapter in this manual is entitled "Chapter
Structuring"; the @chapter line looks like this:

```
    @chapter Chapter Structuring
```

   In TeX, the @chapter command creates a chapter in the document,
specifying the chapter title. The chapter is numbered automatically.

   In Info, the @chapter command causes the title to appear on a line
by itself, with a line of asterisks inserted underneath. Thus, in
Info, the above example produces the following output:

```
    Chapter Structuring
    *******************
```

1.58   texi.info/unnumbered & appendix

```
                    @unnumbered,  @appendix
========================
```

   Use the @unnumbered command to create a chapter that appears in a
printed manual without chapter numbers of any kind. Use the @appendix
command to create an appendix in a printed manual that is labelled by
letter instead of by number.

   For Info file output, the @unnumbered and @appendix commands are
equivalent to @chapter: the title is printed on a line by itself with
a line of asterisks underneath. (See
                @chapter
                .)

   To create an appendix or an unnumbered chapter, write an @appendix
or @unnumbered command at the beginning of a line and follow it on the
same line by the title, as you would if you were creating a chapter.

1.59   texi.info/majorheading & chapheading

```
                    @majorheading,  @chapheading
============================
```

   The @majorheading and @chapheading commands put chapter-like

headings in the body of a document.

   However, neither command causes TeX to produce a numbered heading or
an entry in the table of contents; and neither command causes TeX to
start a new page in a printed manual.

   In TeX, an @majorheading command generates a larger vertical
whitespace before the heading than an @chapheading command but is
otherwise the same.

   In Info, the @majorheading and @chapheading commands are
equivalent to @chapter: the title is printed on a line by itself with
a line of asterisks underneath. (See
                @chapter
                 .)

1.60   texi.info/section

 @section
=========

   In a printed manual, an @section command identifies a numbered
section within a chapter. The section title appears in the table of
contents. In Info, an @section command provides a title for a segment
of text, underlined with =.

   This section is headed with an @section command and looks like this
in the Texinfo file:

     @section @code{@@section}

   To create a section, write the @section command at the beginning of
a line and follow it on the same line by the section title.

   Thus,

     @section This is a section

produces

     This is a section
     ==================

in Info.

1.61   texi.info/unnumberedsec appendixsec heading

                @unnumberedsec, @appendixsec, @heading
==

   The @unnumberedsec, @appendixsec, and @heading commands are,
respectively, the unnumbered, appendix-like, and heading-like
equivalents of the @section command. (See
                @section
                .)

 @unnumberedsec
     The @unnumberedsec command may be used within an unnumbered
     chapter or within a regular chapter or appendix to provide an
     unnumbered section.

 @appendixsec
 @appendixsection
      @appendixsection is a longer spelling of the @appendixsec
     command; the two are synonymous.

     Conventionally, the @appendixsec or @appendixsection command is
     used only within appendices.

 @heading
     You may use the @heading command anywhere you wish for a
     section-style heading that will not appear in the table of
     contents.

1.62   texi.info/subsection

                The @subsection Command
========================

   Subsections are to sections as sections are to chapters. (See

                @section
                .) In Info, subsection titles are underlined with -. For
example,

     @subsection This is a subsection

produces

     This is a subsection

   In a printed manual, subsections are listed in the table of contents
and are numbered three levels deep.

1.63   texi.info/unnumberedsubsec appendixsubsec subheading

```
              The  @subsection-like Commands
==============================
```

   The @unnumberedsubsec, @appendixsubsec, and @subheading commands
are, respectively, the unnumbered, appendix-like, and heading-like
equivalents of the @subsection command. (See
                  @subsection
                  .)

   In Info, the @subsection-like commands generate a title underlined
with hyphens. In a printed manual, an @subheading command produces a
heading like that of a subsection except that it is not numbered and
does not appear in the table of contents. Similarly, an
subsection and an @appendixsubsec command produces a subsection-like
heading labelled with a letter and numbers; both of these commands
produce headings that appear in the table of contents.

1.64 texi.info/subsubsection

```
              The 'subsub' Commands
====================
```

   The fourth and lowest level sectioning commands in Texinfo are the
'subsub' commands. They are:

@subsubsection
     Subsubsections are to subsections as subsections are to sections.
     (See
                  @subsection
                  .) In a printed manual, subsubsection titles
     appear in the table of contents and are numbered four levels deep.

@unnumberedsubsubsec
     Unnumbered subsubsection titles appear in the table of contents of
     a printed manual, but lack numbers. Otherwise, unnumbered
     subsubsections are the same as subsubsections. In Info, unnumbered
     subsubsections look exactly like ordinary subsubsections.

@appendixsubsubsec
     Conventionally, appendix commands are used only for appendices and
     are lettered and numbered appropriately in a printed manual. They
     also appear in the table of contents. In Info, appendix
     subsubsections look exactly like ordinary subsubsections.

@subsubheading
     The @subsubheading command may be used anywhere that you need a
     small heading that will not appear in the table of contents. In
     Info, subsubheadings look exactly like ordinary subsubsection
     headings.

   In Info, 'subsub' titles are underlined with periods. For example,

```
    @subsubsection This is a subsubsection
```

produces

```
    This is a subsubsection
    .......................
```

1.65 texi.info/Nodes

```
                 Nodes
*****
```

   Nodes are the primary segments of a Texinfo file. They do not
themselves impose a hierarchic or any other kind of structure on a file.
Nodes contain node pointers that name other nodes, and can contain
menus which are lists of nodes. In Info, the movement commands can
carry you to a pointed-to node or to a node listed in a menu. Node
pointers and menus provide structure for Info files just as chapters,
sections, subsections, and the like, provide structure for printed
books.

              Two Paths
                              Different commands to structure
                              Info output and printed output.

              Node Menu Illustration
                   A diagram, and sample nodes and menus.

              node
                              How to write a node, in detail.

              makeinfo Pointer Creation
                 How to create node pointers with makeinfo.

1.66 texi.info/Two Paths

```
Two Paths
=========
```

   The node and menu commands and the chapter structuring commands are
independent of each other:

   * In Info, node and menu commands provide structure. The chapter
     structuring commands generate headings with different kinds of
     underlining--asterisks for chapters, hyphens for sections, and so
     on; they do nothing else.

   * In TeX, the chapter structuring commands generate chapter and
     section numbers and tables of contents. The node and menu
     commands provide information for cross references; they do nothing
     else.

   You can use node pointers and menus to structure an Info file any way
you want; and you can write a Texinfo file so that its Info output has a
different structure than its printed output. However, most Texinfo
files are written such that the structure for the Info output
corresponds to the structure for the printed output. It is not
convenient to do otherwise.

   Generally, printed output is structured in a tree-like hierarchy in
which the chapters are the major limbs from which the sections branch
out. Similarly, node pointers and menus are organized to create a
matching structure in the Info output.

1.67   texi.info/Node Menu Illustration

                    Node and Menu Illustration
==========================

   Here is a copy of the diagram shown earlier that illustrates a
Texinfo file with three chapters, each of which contains two sections.

   Note that the "root" is at the top of the diagram and the "leaves"
are at the bottom. This is how such a diagram is drawn conventionally;
it illustrates an upside-down tree. For this reason, the root node is
called the 'Top' node, and 'Up' node pointers carry you closer to the
root.

```
                         Top
                          |
          -----------------------------------
          |                |                 |
      Chapter 1        Chapter 2         Chapter 3
          |                |                 |
      --------         --------          --------
      |      |         |      |          |      |
   Section Section  Section Section   Section Section
     1.1     1.2      2.1     2.2       3.1     3.2
```
   Write the beginning of the node for Chapter 2 like this:

    @node   Chapter 2, Chapter 3, Chapter 1, top
    @comment   node-name, next,   previous, up

This @node line says that the name of this node is "Chapter 2", the
name of the 'Next' node is "Chapter 3", the name of the 'Previous' node
is "Chapter 1", and the name of the 'Up' node is "Top".

     Please Note: 'Next' refers to the next node at the same
     hierarchical level in the manual, not necessarily to the next node

within the Texinfo file. In the Texinfo file, the subsequent node
may be at a lower level--a section-level node may follow a
chapter-level node, and a subsection-level node may follow a
section-level node. 'Next' and 'Previous' refer to nodes at the
same hierarchical level. (The 'Top' node contains the exception
to this rule. Since the 'Top' node is the only node at that
level, 'Next' refers to the first following node, which is almost
always a chapter or chapter-level node.)

   To go to Sections 2.1 and 2.2 using Info, you need a menu inside
Chapter 2. (See
              Menus
              .) You would write the menu just before the
beginning of Section 2.1, like this:

        @menu
        * Sect. 2.1::   Description of this section.
        * Sect. 2.2::
        @end menu

   Write the node for Sect. 2.1 like this:

        @node   Sect. 2.1, Sect. 2.2, Chapter 2, Chapter 2
        @comment node-name, next,   previous, up

   In Info format, the 'Next' and 'Previous' pointers of a node usually
lead to other nodes at the same level--from chapter to chapter or from
section to section (sometimes, as shown, the 'Previous' pointer points
up); an 'Up' pointer usually leads to a node at the level above (closer
to the 'Top' node); and a 'Menu' leads to nodes at a level below (closer
to 'leaves'). (A cross reference can point to a node at any level; see

              Cross References
              .)

   Usually, an @node command and a chapter structuring command are
used in sequence, along with indexing commands. (You may follow the
   Here is the beginning of the chapter in this manual called "Ending a
Texinfo File". This shows an @node line followed by a comment line,
an @chapter line, and then by indexing lines.

   @node   Ending a File, Structuring, Beginning a File, Top
   @comment node-name,   next,   previous,   up
   @chapter Ending a Texinfo File
   @cindex Ending a Texinfo file
   @cindex Texinfo file ending
   @cindex File ending

1.68   texi.info/node

                The @node Command
==================

A node is a segment of text that begins at an @node command and
continues until the next @node command. The definition of node is
different from that for chapter or section. A chapter may contain
sections and a section may contain subsections; but a node cannot
contain subnodes; the text of a node continues only until the next
structuring command, the one that follows the @node line. On the
other hand, in printed output nodes are used only for cross references,
so a chapter or section may contain any number of nodes. Indeed, a
chapter usually contains several nodes, one for each section,
subsection, and subsubsection.

To create a node, write an @node command at the beginning of a
line, and follow it with four arguments, separated by commas, on the
rest of the same line. These arguments are the name of the node, and
the names of the 'Next', 'Previous', and 'Up' pointers, in that order.
You may insert spaces before each pointer if you wish; the spaces are
ignored. You must write the name of the node, and the names of the
'Next', 'Previous', and 'Up' pointers, all on the same line. Otherwise,
the formatters fail. (See info, for more information about nodes in
Info.)

Usually, you write one of the chapter-structuring command lines
immediately after an @node line--for example, an @section or
    Please note: The GNU Emacs Texinfo mode updating commands work
    only with Texinfo files in which @node lines are followed by
    chapter structuring lines. See
              Updating Requirements
              .

TeX uses @node lines to identify the names to use for cross
references. For this reason, you must write @node lines in a Texinfo
file that you intend to format for printing, even if you do not intend
to format it for Info. (Cross references, such as the one at the end
of this sentence, are made with @xref and its related commands; see

              Cross References
              .)

            Node Names
                            How to choose node and pointer names.

            Writing a Node

                            How to write a 'Top' node.

            makeinfo top command
                    How to use the @top command.

```
                    Top Node Summary
                              Write a brief description for readers.
```

1.69   texi.info/Node Names

```
                   Choosing Node and Pointer Names
-----------------------------
```

   The name of a node identifies the node. The pointers enable you to
reach other nodes and consist of the names of those nodes.

   Normally, a node's 'Up' pointer contains the name of the node whose
menu mentions that node. The node's 'Next' pointer contains the name
of the node that follows that node in that menu and its 'Previous'
pointer contains the name of the node that precedes it in that menu.
When a node's 'Previous' node is the same as its 'Up' node, both node
pointers name the same node.

   Usually, the first node of a Texinfo file is the 'Top' node, and its
'Up' and 'Previous' pointers point to the dir file, which contains the
main menu for all of Info.

   The 'Top' node itself contains the main or master menu for the
manual. Also, it is helpful to include a brief description of the
manual in the 'Top' node. See
                   First Node
                   , for information on how to
write the first node of a Texinfo file.

1.70   texi.info/Writing a Node

```
                   How to Write an  @node Line
-------------------------
```

   The easiest way to write an @node line is to write @node at the
beginning of a line and then the name of the node, like this:

     @node node-name

   If you are using GNU Emacs, you can use the update node commands
provided by Texinfo mode to insert the names of the pointers; or you
can leave the pointers out of the Texinfo file and let makeinfo insert
node pointers into the Info file it creates. (See
                   Texinfo Mode
                   , and

                   makeinfo Pointer Creation

.)

Alternatively, you can insert the 'Next', 'Previous', and 'Up'
pointers yourself. If you do this, you may find it helpful to use the
Texinfo mode keyboard command C-c C-c n. This command inserts @node
and a comment line listing the names of the pointers in their proper
order. The comment line helps you keep track of which arguments are
for which pointers. This comment line is especially useful if you are
not familiar with Texinfo.

The template for a node line with 'Next', 'Previous', and 'Up'
pointers looks like this:

     @node node-name, next, previous, up

If you wish, you can ignore @node lines altogether in your first
draft and then use the texinfo-insert-node-lines command to create
is better to name the node itself at the same time that you write a
segment so you can easily make cross references. A large number of
cross references are an especially important feature of a good Info
file.

After you have inserted an @node line, you should immediately write
an @-command for the chapter or section and insert its name. Next (and
this is important!), put in several index entries. Usually, you will
find at least two and often as many as four or five ways of referring
to the node in the index. Use them all. This will make it much easier
for people to find the node.

1.71 texi.info/Node Line Tips

 @node Line Tips

Here are three suggestions:

* Try to pick node names that are informative but short.

  In the Info file, the file name, node name, and pointer names are
  all inserted on one line, which may run into the right edge of the
  window. (This does not cause a problem with Info, but is ugly.)

* Try to pick node names that differ from each other near the
  beginnings of their names. This way, it is easy to use automatic
  name completion in Info.

* By convention, node names are capitalized just as they would be for
  section or chapter titles--initial and significant words are
  capitalized; others are not.

1.72   texi.info/Node Line Requirements

```
 @node Line Requirements
 -----------------------
```

   Here are several requirements for @node lines:

 * All the node names for a single Info file must be unique.

   Duplicates confuse the Info movement commands. This means, for
   example, that if you end every chapter with a summary, you must
   name each summary node differently. You cannot just call each one
   "Summary". You may, however, duplicate the titles of chapters,
   sections, and the like. Thus you can end each chapter in a book
   with a section called "Summary", so long as the node names for
   those sections are all different.

 * A pointer name must be the name of a node.

   The node to which a pointer points may come before or after the
   node containing the pointer.

 * You cannot use any of the Texinfo @-commands in a node name;
   @-commands confuse Info.

   Thus, the beginning of the section called @chapter looks like
   this:

```
       @node  chapter, unnumbered & appendix, makeinfo top, Structuring
       @comment  node-name,  next,  previous,  up
       @section @code{@@chapter}
       @findex chapter
```

 * You cannot use commas, colons, or apostrophes within a node name;
   these confuse TeX or the Info formatters.

   For example, the following is a section title:

```
       @code{@@unnumberedsec}, @code{@@appendixsec}, @code{@@heading}
```

   The corresponding node name is:

```
       unnumberedsec appendixsec heading
```

 * Case is significant.

1.73   texi.info/First Node

```
                 The First Node
 --------------
```

   The first node of a Texinfo file is the 'Top' node, except in an
included file (see

```
                    Include Files
                    ).
```

   The 'Top' node (which must be named top or Top) should have as its
'Up' and 'Previous' nodes the name of a node in another file, where
there is a menu that leads to this file. Specify the file name in
parentheses. If the file is to be installed directly in the Info
directory file, use (dir) as the parent of the 'Top' node; this is
short for (dir)top, and specifies the 'Top' node in the dir file, which
contains the main menu for Info. For example, the @node Top line of
this manual looks like this:

     @node Top, Overview, (dir), (dir)

(You may use the Texinfo updating commands or the makeinfo utility to
insert these 'Next' and (dir) pointers automatically.)

   See
                 Install an Info File
                 , for more information about installing an
Info file in the info directory.

   The 'Top' node contains the main or master menu for the document.

1.74   texi.info/makeinfo top command

```
The  @top Sectioning Command
----------------------------
```

   A special sectioning command, @top, has been created for use with
the @node Top line. The @top sectioning command tells makeinfo that
it marks the 'Top' node in the file. It provides the information that
makeinfo needs to insert node pointers automatically. Write the @top
command at the beginning of the line immediately following the @node
Top line. Write the title on the remaining part of the same line as the
 @top command.

   In Info, the @top sectioning command causes the title to appear on a
line by itself, with a line of asterisks inserted underneath.

   In TeX and texinfo-format-buffer, the @top sectioning command is
merely a synonym for @unnumbered. Neither of these formatters require
an @top command, and do nothing special with it. You can use
these formatters. Also, you can use @chapter or @unnumbered when you
use the Texinfo updating commands to create or update pointers and
menus.

   Whatever sectioning command follows an @node Top line, whether it
be @top or @chapter, the @node Top line and the immediately
following line and any additional text must be enclosed between
prevents the title and the accompanying text from appearing in printed
output. Write the @ifinfo command before the @node line and write
the @end ifinfo command after the @top or other sectioning command

and after any additional text. (You can write the @end ifinfo command
after the @end menu command if you like.)

1.75   texi.info/Top Node Summary

                    The 'Top' Node Summary

   You can help readers by writing a summary in the 'Top' node, after
the @top line, before the main or master menu. The summary should
briefly describe the Info file. You should also write the version
number of the program to which the manual applies in this section. This
helps the reader keep track of which manual is for which version of the
program. If the manual changes more frequently than the program or is
independent of it, you should also include an edition number for the
manual. (The title page should also contain this information: see

                @titlepage
                .)

   Put the whole of the 'Top' node, including the @top sectioning
command line if you have one, between @ifinfo and @end ifinfo so none
of the text appears in the printed output (see

                Conditionally Visible Text
). (You may want to repeat the brief
description from the 'Top' node within @iftex ... @end iftex at the
beginning of the first chapter, for those who read the printed manual.)

1.76   texi.info/makeinfo Pointer Creation

                Creating Pointers with makeinfo
================================

   The makeinfo program has a feature for automatically creating node
pointers for a hierarchically organized file that lacks them.

   When you take advantage of this feature, you do not need to write the
'Next', 'Previous', and 'Up' pointers after the name of a node.
However, you must write a sectioning command, such as @chapter or
You cannot write a comment line after a node line; the section line
must follow it immediately.

   In addition, you must follow the 'Top' @node line with a line
beginning with @top to mark the 'Top' node in the file. See
                @top
                .

   Finally, you must write the name of each node (except for the 'Top'

node) in a menu that is one or more hierarchical levels above the
node's hierarchical level.

   This node pointer insertion feature in makeinfo is an alternative to
the menu and pointer creation and update commands in Texinfo mode.
(See
                 Updating Nodes and Menus
                 .) It is especially helpful to people who
do not use GNU Emacs for writing Texinfo documents.

1.77 texi.info/Menus

                 Menus
*****

   Menus contain pointers to subordinate nodes.(1) In Info, you use
menus to go to such nodes. Menus have no effect in printed manuals and
do not appear in them.

   By convention, a menu is put at the end of a node since a reader who
uses the menu may not see text that follows it.

   A node that has a menu should not contain much text. If you have a
lot of text and a menu, move most of the text into a new subnode--all
but a few lines.

                 Menu Location
                                Put a menu in a short node.

                 Writing a Menu
                                What is a menu?

                 Menu Parts
                                A menu entry has three parts.

                 Less Cluttered Menu Entry
                    Two part menu entry.

                 Menu Example
                                Two and three part menu entries.

                 Other Info Files
                                How to refer to a different Info file.

   ---------- Footnotes ----------

   (1) Menus can carry you to any node, regardless of the hierarchical
structure; even to nodes in a different Info file. However, the GNU
Emacs Texinfo mode updating commands work only to create menus of
subordinate nodes. Conventionally, cross references are used to refer
to other nodes.

1.78   texi.info/Menu Location

```
Menus Need Short Nodes
======================
```

   A reader can easily see a menu that is close to the beginning of the
node. The node should be short. As a practical matter, you should
locate a menu within 20 lines of the beginning of the node. Otherwise,
a reader with a terminal that displays only a few lines may miss the
menu and its associated text.

   The short text before a menu may look awkward in a printed manual.
To avoid this, you can write a menu near the beginning of its node and
follow the menu by an @node line, and then an @heading line located
within @ifinfo and @end ifinfo. This way, the menu, @node line, and
title appear only in the Info file, not the printed document.

```
   For example, the preceding two paragraphs follow an Info-only menu,
   @menu
   * Menu Location::              Put a menu in a short node.
   * Writing a Menu::             What is a menu?
   * Menu Parts::                 A menu entry has three parts.
   * Less Cluttered Menu Entry:: Two part menu entry.
   * Menu Example::               Two and three part entries.
   * Other Info Files::           How to refer to a different
                                    Info file.
   @end menu

   @node Menu Location, Writing a Menu,  , Menus
   @ifinfo
   @heading Menus Need Short Nodes
   @end ifinfo
```

   The Texinfo file for this document contains more than a dozen
examples of this procedure. One is at the beginning of this chapter;
another is at the beginning of the "Cross References" chapter.

1.79   texi.info/Writing a Menu

```
Writing a Menu
==============
```

   A menu consists of an @menu command on a line by itself followed by
menu entry lines or menu comment lines and then by an @end menu
command on a line by itself.

   A menu looks like this:

```
    @menu
    Larger Units of Text

    * Files::                        All about handling files.
    * Multiples: Buffers.            Multiple buffers; editing
                                       several files at once.
    @end menu
```

In a menu, every line that begins with an * is a menu entry. (Note the space after the asterisk.) A line that does not start with an * may also appear in a menu. Such a line is not a menu entry but is a menu comment line that appears in the Info file. In the example above, the line Larger Units of Text is a menu comment line; the two lines starting with * are menu entries.

1.80 texi.info/Menu Parts

```
The Parts of a Menu
===================
```

A menu entry has three parts, only the second of which is required:

1. The menu entry name.

2. The name of the node (required).

3. A description of the item.

The template for a menu entry looks like this:

```
    * menu-entry-name: node-name.    description
```

Follow the menu entry name with a single colon and follow the node name with tab, comma, period, or newline.

In Info, a user selects a node with the m (Info-menu) command. The menu entry name is what the user types after the m command.

The third part of a menu entry is a descriptive phrase or sentence. Menu entry names and node names are often short; the description explains to the reader what the node is about. The description, which is optional, can spread over two or more lines. A useful description complements the node name rather than repeats it.

1.81 texi.info/Less Cluttered Menu Entry

```
Less Cluttered Menu Entry
=========================
```

When the menu entry name and node name are the same, you can write

the name immediately after the asterisk and space at the beginning of
the line and follow the name with two colons.

   For example, write

     * Name::   description

instead of

     * Name: Name.   description

   You should use the node name for the menu entry name whenever
possible, since it reduces visual clutter in the menu.

1.82   texi.info/Menu Example

                  A Menu Example
==============

   A menu looks like this in Texinfo:

     @menu
     * menu entry name: Node name.   A short description.
     * Node name::   This form is preferred.
     @end menu

This produces:

     * menu:

     * menu entry name: Node name.   A short description.
     * Node name::   This form is preferred.

   Here is an example as you might see it in a Texinfo file:

     @menu
     Larger Units of Text

     * Files::   All about handling files.
     * Multiples: Buffers.   Multiple buffers; editing
                                        several files at once.
     @end menu

This produces:

     * menu:
     Larger Units of Text

     * Files::   All about handling files.
     * Multiples: Buffers.   Multiple buffers; editing
                                        several files at once.

   In this example, the menu has two entries. Files is both a menu
entry name and the name of the node referred to by that name.

Multiples is the menu entry name; it refers to the node named
Buffers. The line Larger Units of Text is a comment; it appears in the
menu, but is not an entry.

   Since no file name is specified with either Files or Buffers, they
must be the names of nodes in the same Info file (see

                 Referring to Other Info Files
).

1.83 texi.info/Other Info Files

                 Referring to Other Info Files
==============================

   You can create a menu entry that enables a reader in Info to go to a
node in another Info file by writing the file name in parentheses just
before the node name. In this case, you should use the three-part menu
entry format, which saves the reader from having to type the file name.

   The format looks like this:

     @menu
     * first-entry-name:(filename)nodename.   description
     * second-entry-name:(filename)second-node. description
     @end menu

   For example, to refer directly to the Outlining and Rebinding nodes
in the 'Emacs Manual', you would write a menu like this:

     @menu
     * Outlining: (emacs)Outline Mode. The major mode for
                                       editing outlines.
     * Rebinding: (emacs)Rebinding.   How to redefine the
                                       meaning of a key.
     @end menu

   If you do not list the node name, but only name the file, then Info
presumes that you are referring to the 'Top' node.

   The dir file that contains the main menu for Info has menu entries
that list only file names. These take you directly to the 'Top' nodes
of each Info document. (See
                 Install an Info File
                 .)

   For example:

     * Info: (info).   Documentation browsing system.
     * Emacs: (emacs).   The extensible, self-documenting
                             text editor.

(The dir top level directory for the Info system is an Info file, not a

Texinfo file, but a menu entry looks the same in both types of file.)

   Note that the GNU Emacs Texinfo mode menu updating commands only work
with nodes within the current buffer, so you cannot use them to create
menus that refer to other files. You must write such menus by hand.

1.84 texi.info/Cross References

                   Cross References
****

   Cross references are used to refer the reader to other parts of the
same or different Texinfo files. In Texinfo, nodes are the places to
which cross references can refer.

            References
                             What cross references are for.

            Cross Reference Commands
                A summary of the different commands.

            Cross Reference Parts
                 A cross reference has several parts.

            xref
                                 Begin a reference with 'See' ...

            Top Node Naming
                     How to refer to the beginning of another file.

            ref
                                 A reference for the last part of a ←
                                     sentence.

            pxref
                                 How to write a parenthetical cross ←
                                     reference.

            inforef
                             How to refer to an Info-only file.

1.85 texi.info/References

What References Are For
=======================

Often, but not always, a printed document should be designed so that
it can be read sequentially. People tire of flipping back and forth to
find information that should be presented to them as they need it.

However, in any document, some information will be too detailed for
the current context, or incidental to it; use cross references to
provide access to such information. Also, an on-line help system or a
reference manual is not like a novel; few read such documents in
sequence from beginning to end. Instead, people look up what they
need. For this reason, such creations should contain many cross
references to help readers find other information that they may not
have read.

In a printed manual, a cross reference results in a page reference,
unless it is to another manual altogether, in which case the cross
reference names that manual.

In Info, a cross reference results in an entry that you can follow
using the Info f command. (See Some advanced Info commands.)

The various cross reference commands use nodes to define cross
reference locations. This is evident in Info, in which a cross
reference takes you to the specified node. TeX also uses nodes to
define cross reference locations, but the action is less obvious. When
TeX generates a DVI file, it records nodes' page numbers and uses the
page numbers in making references. Thus, if you are writing a manual
that will only be printed, and will not be used on-line, you must
nonetheless write @node lines to name the places to which you make
cross references.

1.86   texi.info/Cross Reference Commands

                    Different Cross Reference Commands
====================================

There are four different cross reference commands:

@xref
     Used to start a sentence in the printed manual saying 'See ...' or
     an entry in the Info file saying *Note ....

@ref
     Used within or, more often, at the end of a sentence; same as
     @xref for Info; produces just the reference in the printed manual
     without a preceding 'See'.

@pxref
     Used within parentheses to make a reference that suits both an Info
     file and a printed book. Starts with a lower case 'see' within the
     printed manual. (p is for 'parenthesis'.)

@inforef
     Used to make a reference to an Info file for which there is no
     printed manual.

(The @cite command is used to make references to books and manuals for
which there is no corresponding Info file and, therefore, no node to
which to point.   See
              @cite
              .)

1.87   texi.info/Cross Reference Parts

Parts of a Cross Reference
==========================

   A cross reference command requires only one argument, which is the
name of the node to which it refers. But a cross reference command may
contain up to four additional arguments. By using these arguments, you
can provide a cross reference name for Info, a topic description or
section title for the printed output, the name of a different Info
file, and the name of a different printed manual.

   Here is a simple cross reference example:

     @xref{Node name}.

which produces

     *Note Node name::.

and

     See Section nnn [Node name], page ppp.

   Here is an example of a full five-part cross reference:

     @xref{Node name, Cross Reference Name, Particular Topic,
     info-file-name, A Printed Manual}, for details.

which produces

     *Note Cross Reference Name: (info-file-name)Node name,
     for details.

in Info and

     See section "Particular Topic" in A Printed Manual, for details.

in a printed book.

   The five possible arguments for a cross reference are:

  1. The node name (required). This is the node to which the cross
     reference takes you. In a printed document, the location of the
     node provides the page reference only for references within the
     same document.

2. The cross reference name for the Info reference, if it is to be
   different from the node name. If you include this argument, it
   argument becomes the first part of the cross reference. It is
   usually omitted.

3. A topic description or section name. Often, this is the title of
   the section. This is used as the name of the reference in the
   printed manual. If omitted, the node name is used.

4. The name of the Info file in which the reference is located, if it
   is different from the current file.

5. The name of a printed manual from a different Texinfo file.

   The template for a full five argument cross reference looks like
this:

        @xref{node-name, cross-reference-name, title-or-topic,
        info-file-name, printed-manual-title }.

   Cross references with one, two, three, four, and five arguments are
described separately following the description of @xref.

   Write a node name in a cross reference in exactly the same way as in
the @node line, including the same capitalization; otherwise, the
formatters may not find the reference.

   You can write cross reference commands within a paragraph, but note
how Info and TeX format the output of each of the various commands:
write @xref at the beginning of a sentence; write @pxref only within
parentheses, and so on.

1.88 texi.info/xref

                      @xref

======

   The @xref command generates a cross reference for the beginning of
a sentence. The Info formatting commands convert it into an Info cross
reference, which the Info f command can use to bring you directly to
another node. The TeX typesetting commands convert it into a page
reference, or a reference to another book or manual.

                Reference Syntax
                          What a reference looks like and requires.

                One Argument
                          @xref with one argument.

                Two Arguments
                          @xref with two arguments.

```
                 Three Arguments
                           @xref with three arguments.

             Four and Five Arguments
                     @xref with four and five arguments.
```

1.89   texi.info/Reference Syntax

```
                What a Reference Looks Like and Requires
-----------------------------------------
```

   Most often, an Info cross reference looks like this:

     *Note node-name::.

or like this

     *Note cross-reference-name: node-name.

In TeX, a cross reference looks like this:

     See Section section-number [node-name], page page.

or like this

     See Section section-number [title-or-topic], page page.

   The @xref command does not generate a period or comma to end the
cross reference in either the Info file or the printed output. You
must write that period or comma yourself; otherwise, Info will not
recognize the end of the reference. (The @pxref command works
differently. See
                  @pxref
                  .)

     Please note: A period or comma must follow the closing brace of an
      @xref. It is required to terminate the cross reference. This
      period or comma will appear in the output, both in the Info file
      and in the printed manual.

     @xref must refer to an Info node by name. Use @node to define the
node (see
                  Writing a Node
).

     @xref is followed by several arguments inside braces, separated by
commas. Whitespace before and after these commas is ignored.

   A cross reference requires only the name of a node; but it may
contain up to four additional arguments. Each of these variations
produces a cross reference that looks somewhat different.

Please note: Commas separate arguments in a cross reference; avoid
including them in the title or other part lest the formatters
mistake them for separators.

1.90   texi.info/One Argument

 @xref with One Argument

   The simplest form of @xref takes one argument, the name of another
node in the same Info file.   The Info formatters produce output that
the Info readers can use to jump to the reference; TeX produces output
that specifies the page and section number for you.

For example,

     @xref{Tropical Storms}.

produces

     *Note Tropical Storms::.

and

     See Section 3.1 [Tropical Storms], page 24.

(Note that in the preceding example the closing brace is followed by a
period.)

   You can write a clause after the cross reference, like this:

     @xref{Tropical Storms}, for more info.

which produces

     *Note Tropical Storms::, for more info.

     See Section 3.1 [Tropical Storms], page 24, for more info.

(Note that in the preceding example the closing brace is followed by a
comma, and then by the clause, which is followed by a period.)

1.91   texi.info/Two Arguments

 @xref with Two Arguments

   With two arguments, the second is used as the name of the Info cross
reference, while the first is still the name of the node to which the

cross reference points.

The template is like this:

    @xref{node-name, cross-reference-name }.

For example,

    @xref{Electrical Effects, Lightning}.

produces:

    *Note Lightning: Electrical Effects.

and

    See Section 5.2 [Electrical Effects], page 57.

(Note that in the preceding example the closing brace is followed by a
period; and that the node name is printed, not the cross reference
name.)

   You can write a clause after the cross reference, like this:

    @xref{Electrical Effects, Lightning}, for more info.

which produces
    *Note Lightning: Electrical Effects, for more info.

and

    See Section 5.2 [Electrical Effects], page 57, for more info.

(Note that in the preceding example the closing brace is followed by a
comma, and then by the clause, which is followed by a period.)

1.92 texi.info/Three Arguments

 @xref with Three Arguments

   A third argument replaces the node name in the TeX output. The third
argument should be the name of the section in the printed output, or
else state the topic discussed by that section. Often, you will want to
use initial upper case letters so it will be easier to read when the
reference is printed. Use a third argument when the node name is
unsuitable because of syntax or meaning.

   Remember to avoid placing a comma within the title or topic section
of a cross reference, or within any other section. The formatters
divide cross references into arguments according to the commas; a comma
within a title or other section will divide it into two arguments. In
a reference, you need to write a title such as "Clouds, Mist, and Fog"
without the commas.

Also, remember to write a comma or period after the closing brace of
a @xref to terminate the cross reference. In the following examples,
a clause follows a terminating comma.

The template is like this:

    @xref{node-name, cross-reference-name, title-or-topic }.

For example,

    @xref{Electrical Effects, Lightning, Thunder and Lightning},
    for details.

produces

    *Note Lightning: Electrical Effects, for details.

and

    See Section 5.2 [Thunder and Lightning], page 57, for details.

   If a third argument is given and the second one is empty, then the
third argument serves both. (Note how two commas, side by side, mark
the empty second argument.)

    @xref{Electrical Effects, , Thunder and Lightning},
    for details.

produces

    *Note Thunder and Lightning: Electrical Effects, for details.

and

    See Section 5.2 [Thunder and Lightning], page 57, for details.

   As a practical matter, it is often best to write cross references
with just the first argument if the node name and the section title are
the same, and with the first and third arguments if the node name and
title are different.

   Here are several examples from 'The GAWK Manual':

    @xref{Sample Program}.
    @xref{Glossary}.
    @xref{Case-sensitivity, ,Case-sensitivity in Matching}.
    @xref{Close Output, , Closing Output Files and Pipes},
       for more information.
    @xref{Regexp, , Regular Expressions as Patterns}.

1.93   texi.info/Four and Five Arguments

 @xref with Four and Five Arguments

    In a cross reference, a fourth argument specifies the name of another
Info file, different from the file in which the reference appears, and
a fifth argument specifies its title as a printed manual.

    Remember that a comma or period must follow the closing brace of an
examples, a clause follows a terminating comma.

The template is:

      @xref{node-name, cross-reference-name, title-or-topic,
      info-file-name, printed-manual-title }.

For example,

      @xref{Electrical Effects, Lightning, Thunder and Lightning,
      weather, An Introduction to Meteorology}, for details.

produces

      *Note Lightning: (weather)Electrical Effects, for details.

The name of the Info file is enclosed in parentheses and precedes the
name of the node.

In a printed manual, the reference looks like this:

      See section "Thunder and Lightning" in An Introduction to
      Meteorology, for details.

The title of the printed manual is typeset in italics; and the
reference lacks a page number since TeX cannot know to which page a
reference refers when that reference is to another manual.

    Often, you will leave out the second argument when you use the long
version of @xref. In this case, the third argument, the topic
description, will be used as the cross reference name in Info.

The template looks like this:

      @xref{node-name, , title-or-topic, info-file-name,
      printed-manual-title }, for details.

which produces

      *Note title-or-topic: (info-file-name)node-name, for details.

and

      See section title-or-topic in printed-manual-title, for details.

For example,

      @xref{Electrical Effects, , Thunder and Lightning,
      weather, An Introduction to Meteorology}, for details.

produces

    *Note Thunder and Lightning: (weather)Electrical Effects,
    for details.

and

    See section "Thunder and Lightning" in An Introduction to
    Meteorology, for details.

   On rare occasions, you may want to refer to another Info file that
is within a single printed manual--when multiple Texinfo files are
incorporated into the same TeX run but make separate Info files. In
this case, you need to specify only the fourth argument, and not the
fifth.

1.94   texi.info/Top Node Naming

                   Naming a 'Top' Node
===================

   In a cross reference, you must always name a node. This means that
in order to refer to a whole manual, you must identify the 'Top' node by
writing it as the first argument to the @xref command. (This is
different from the way you write a menu entry; see

                   Referring to Other Info Files
                   .) At the same time, to provide a
meaningful section topic or title in the printed cross reference
(instead of the word 'Top'), you must write an appropriate entry for
the third argument to the @xref command.

Thus, to make a cross reference to 'The GNU Make Manual', write:

    @xref{Top, , Overview, make, The GNU Make Manual}.

which produces

    *Note Overview: (make)Top.

and

    See section "Overview" in The GNU Make Manual.

In this example, Top is the name of the first node, and Overview is the
name of the first section of the manual.

1.95   texi.info/ref

```
 @ref
=====
```

@ref is nearly the same as @xref except that it does not generate a 'See' in the printed output, just the reference itself. This makes it useful as the last part of a sentence.

For example,

```
     For more information, see @ref{Hurricanes}.
```

produces

```
     For more information, see *Note Hurricanes.
```

and

```
     For more information, see Section 8.2 [Hurricanes], page 123.
```

The @ref command sometimes leads writers to express themselves in a manner that is suitable for a printed manual but looks awkward in the Info format. Bear in mind that your audience will be using both the printed and the Info format.

For example,

```
     Sea surges are described in @ref{Hurricanes}.
```

produces

```
     Sea surges are described in Section 6.7 [Hurricanes], page 72.
```

in a printed document, and the following in Info:

```
     Sea surges are described in *Note Hurricanes::.

     Caution: You must write a period or comma immediately after an
     @ref command with two or more arguments.  Otherwise, Info will not
     find the end of the cross reference entry and its attempt to
     follow the cross reference will fail.  As a general rule, you
     should write a period or comma after every  @ref command.  This
     looks best in both the printed and the Info output.
```

1.96 texi.info/pxref

```
                @pxref
=======
```

The parenthetical reference command, @pxref, is nearly the same as comma or period after the command's closing brace. The command differs from @xref in two ways:

  1. TeX typesets the reference for the printed manual with a lower case

'see' rather than an upper case 'See'.

2. The Info formatting commands automatically end the reference with a
   closing colon or period.

Because one type of formatting automatically inserts closing
punctuation and the other does not, you should use @pxref only inside
parentheses as part of another sentence. Also, you yourself should not
insert punctuation after the reference, as you do with @xref.

@pxref is designed so that the output looks right and works right
between parentheses both in printed output and in an Info file. In a
printed manual, a closing comma or period should not follow a cross
reference within parentheses; such punctuation is wrong. But in an
Info file, suitable closing punctuation must follow the cross reference
so Info can recognize its end.   @pxref spares you the need to use
complicated methods to put a terminator into one form of the output and
not the other.

With one argument, a parenthetical cross reference looks like this:

        ... storms cause flooding (@pxref{Hurricanes}) ...

which produces

        ... storms cause flooding (*Note Hurricanes::) ...

and

        ... storms cause flooding (see Section 6.7 [Hurricanes], page 72)
        ...

With two arguments, a parenthetical cross reference has this
template:

        ... (@pxref{node-name, cross-reference-name }) ...

which produces

        ... (*Note cross-reference-name: node-name.) ...

and

        ... (see Section nnn [node-name], page ppp) ...

@pxref can be used with up to five arguments just like @xref (see

                @xref
).

Please note: Use @pxref only as a parenthetical reference. Do
not try to use @pxref as a clause in a sentence. It will look
bad in either the Info file, the printed output, or both.

Also, parenthetical cross references look best at the ends of
sentences. Although you may write them in the middle of a
sentence, that location breaks up the flow of text.

1.97   texi.info/inforef

                              @inforef
=========

     @inforef is used for cross references to Info files for which there
are no printed manuals. Even in a printed manual, @inforef generates
a reference directing the user to look in an Info file.

   The command takes either two or three arguments, in the following
order:

  1. The node name.

  2. The cross reference name (optional).

  3. The Info file name.

Separate the arguments with commas, as with @xref. Also, you must
terminate the reference with a comma or period after the }, as you do
with @xref.

The template is:

     @inforef{node-name, cross-reference-name, info-file-name },

Thus,

     @inforef{Expert, Advanced Info commands, info},
     for more information.

produces

     *Note Advanced Info commands: (info)Expert,
     for more information.

and

     See Info file info, node Expert, for more information.

Similarly,

     @inforef{Expert, , info}, for more information.

produces

     *Note (info)Expert::, for more information.

and

     See Info file info, node Expert, for more information.

   The converse of @inforef is @cite, which is used to refer to
printed works for which no Info form exists. See
                @cite
                      .

1.98 texi.info/Marking Text

                Marking Words and Phrases
****

   In Texinfo, you can mark words and phrases in a variety of ways.
The Texinfo formatters use this information to determine how to
highlight the text. You can specify, for example, whether a word or
phrase is a defining occurrence, a metasyntactic variable, or a symbol
used in a program. Also, you can emphasize text.

        Indicating
                          How to indicate definitions, files, etc.

        Emphasis
                          How to emphasize text.

1.99 texi.info/Indicating

                Indicating Definitions, Commands, etc.
==

   Texinfo has commands for indicating just what kind of object a piece
of text refers to. For example, metasyntactic variables are marked by
commands that tell what kind of object they are, it is easy to change
the way the Texinfo formatters prepare such text. (Texinfo is an
intentional formatting language rather than a typesetting formatting
language.)

   For example, in a printed manual, code is usually illustrated in a
typewriter font; @code tells TeX to typeset this text in this font.
But it would be easy to change the way TeX highlights code to use
another font, and this change would not effect how keystroke examples
are highlighted. If straight typesetting commands were used in the body
of the file and you wanted to make a change, you would need to check
every single occurrence to make sure that you were changing code and
not something else that should not be changed.

                Useful Highlighting

                         Highlighting provides useful information.

            code
                                How to indicate code.

            kbd
                                 How to show keyboard input.

            key
                                 How to specify keys.

            samp
                                How to show a literal sequence of ←
                                    characters.

            var
                                 How to indicate a metasyntactic variable ←
                                     .

            file
                                How to indicate the name of a file.

            dfn
                                 How to specify a definition.

            cite
                                How to refer to a book that is not in ←
                                    Info.

1.100   texi.info/Useful Highlighting

Highlighting Commands are Useful

    The highlighting commands can be used to generate useful information
from the file, such as lists of functions or file names. It is
possible, for example, to write a program in Emacs Lisp (or a keyboard
macro) to insert an index entry after every paragraph that contains
words or phrases marked by a specified command. You could do this to
construct an index of functions if you had not already made the entries.

    The commands serve a variety of purposes:

 @code{sample-code }
     Indicate text that is a literal example of a piece of a program.

 @kbd{keyboard-characters }
     Indicate keyboard input.

 @key{key-name }
     Indicate the conventional name for a key on a keyboard.

 @samp{text }

    Indicate text that is a literal example of a sequence of
    characters.

 @var{metasyntactic-variable }
    Indicate a metasyntactic variable.

 @file{file-name }
    Indicate the name of a file.

 @dfn{term }
    Indicate the introductory or defining use of a term.

 @cite{reference }
    Indicate the name of a book.

1.101 texi.info/code

 @code {sample-code }

   Use the @code command to indicate text that is a piece of a program
and which consists of entire syntactic tokens. Enclose the text in
braces.

   Thus, you should use @code for an expression in a program, for the
name of a variable or function used in a program, or for a keyword.
Also, you should use @code for the name of a program, such as diff,
that is a name used in the machine. (You should write the name of a
program in the ordinary text font if you regard it as a new English
word, such as 'Emacs' or 'Bison'.)

   Use @code for environment variables such as TEXINPUTS, and other
variables.

   Use @code for command names in command languages that resemble
programming languages, such as Texinfo or the shell. For example,
   Note, however, that you should not use @code for shell options such
as -c when such options stand alone. (Use @samp.) Also, an entire
shell command often looks better if written using @samp rather than
   It is incorrect to alter the case of a word inside an @code command
when it appears at the beginning of a sentence. Most computer
languages are case sensitive. In C, for example, Printf is different
from the identifier printf, and most likely is a misspelling of it.
Even in languages which are not case sensitive, it is confusing to a
human reader to see identifiers spelled in different ways. Pick one
spelling and always use that. If you do not want to start a sentence
with a command written all in lower case, you should rearrange the
sentence.

   Do not use the @code command for a string of characters shorter
than a syntactic token. If you are writing about TEXINPU, which is
just a part of the name for the TEXINPUTS environment variable, you
should use @samp.

In particular, you should not use the @code command when writing
about the characters used in a token; do not, for example, use @code
when you are explaining what letters or printable symbols can be used
in the names of functions. (Use @samp.) Also, you should not use
input is written in a language that is like a programming language.
For example, you should not use @code for the keystroke commands of
GNU Emacs (use @kbd instead) although you may use @code for the names
of the Emacs Lisp functions that the keystroke commands invoke.

   In the printed manual, @code causes TeX to typeset the argument in
a typewriter face. In the Info file, it causes the Info formatting
commands to use single quotation marks around the text.

   For example,

      Use @code{diff} to compare two files.

produces this in the printed manual:

      Use diff to compare two files.

1.102   texi.info/kbd

 @kbd {keyboard-characters }

   Use the @kbd command for characters of input to be typed by users.
For example, to refer to the characters M-a, write

      @kbd{M-a}

and to refer to the characters M-x shell, write

      @kbd{M-x shell}

   The @kbd command has the same effect as @code in Info, but may
produce a different font in a printed manual.

   You can embed another @-command inside the braces of an @kbd
command. Here, for example, is the way to describe a command that
would be described more verbosely as "press an r and then press the RET
key":

      @kbd{r @key{RET}}

This produces: r RET

   You also use the @kbd command if you are spelling out the letters
you type; for example:

      To give the @code{logout} command,
      type the characters @kbd{l o g o u t @key{RET}}.

This produces:

To give the logout command, type the characters l o g o u t RET.

   (Also, this example shows that you can add spaces for clarity. If
you really want to mention a space character as one of the characters of
input, write @key{SPC} for it.)

1.103 texi.info/key

 @key {key-name }

   Use the @key command for the conventional name for a key on a
keyboard, as in:

     @key{RET}

   You can use the @key command within the argument of an @kbd
command when the sequence of characters to be typed includes one or
more keys that are described by name.

   For example, to produce C-x ESC you would type:

     @kbd{C-x @key{ESC}}

   Here is a list of the recommended names for keys; they are all in
upper case:

   SPC
         Space

   RET
         Return

   LFD
         Linefeed

   TAB
         Tab

   BS
         Backspace

   ESC
         Escape

   DEL
         Delete

   SFT
         Shift

   CTL
         Control

```
     META
           Meta
```

There are subtleties to handling words like 'meta' or 'ctl' that are
names of shift keys. When mentioning a character in which the shift
key is used, such as Meta-a, use the @kbd command alone; do not use
the @key command; but when you are referring to the shift key in
isolation, use the @key command. For example, write @kbd{Meta-a} to
produce Meta-a and @key{META} to produce META. This is because Meta-a
refers to keys that you press on a keyboard, but META refers to a key
without implying that you press it. In short, use @kbd for what you
do, and use @key for what you talk about: "Press @kbd{M-a} to move
point to the beginning of the sentence. The @key{META} key is often
in the lower left of the keyboard."

1.104 texi.info/samp

```
 @samp {text }
 --------------
```

Use the @samp command to indicate text that is a literal example or
'sample' of a sequence of characters in a file, string, pattern, etc.
Enclose the text in braces. The argument appears within single
quotation marks in both the Info file and the printed manual; in
addition, it is printed in a fixed-width font.

```
     To match @samp{foo} at the end of the line,
     use the regexp @samp{foo$}.
```

produces

```
     To match foo at the end of the line, use the regexp foo$.
```

Any time you are referring to single characters, you should use
command-line options. Also, you may use @samp for entire statements
in C and for entire shell commands--in this case, @samp often looks
better than @code. Basically, @samp is a catchall for whatever is
not covered by @code, @kbd, or @key.

Only include punctuation marks within braces if they are part of the
string you are specifying. Write punctuation marks outside the braces
if those punctuation marks are part of the English text that surrounds
the string. In the following sentence, for example, the commas and
period are outside of the braces:

```
     In English, the vowels are @samp{a}, @samp{e},
     @samp{i}, @samp{o}, @samp{u}, and sometimes
     @samp{y}.
```

This produces:

```
     In English, the vowels are a, e, i, o, u,  and sometimes y.
```

1.105 texi.info/var

```
 @var {metasyntactic-variable }
-----------------------------
```

   Use the @var command to indicate metasyntactic variables. A
metasyntactic variable is something that stands for another piece of
text. For example, you should use a metasyntactic variable in the
documentation of a function to describe the arguments that are passed
to that function.

   Do not use @var for the names of particular variables in
programming languages. These are specific names from a program, so
texinfo-tex-command is not a metasyntactic variable; it is properly
formatted using @code.

   The effect of @var in the Info file is to change the case of the
argument to all upper case; in the printed manual, to italicize it.

   For example,

```
    To delete file @var{filename},
    type @code{rm @var{filename}}.
```

produces

```
    To delete file filename, type rm filename.
```

(Note that @var may appear inside @code, @samp, @file, etc.)

   Write a metasyntactic variable all in lower case without spaces, and
use hyphens to make it more readable. Thus, the Texinfo source for the
illustration of how to begin a Texinfo manual looks like this:

```
    \input texinfo
    @@setfilename @var{info-file-name}
    @@settitle @var{name-of-manual}
```

This produces:

```
    \input texinfo
    @setfilename info-file-name
    @settitle name-of-manual
```

   In some documentation styles, metasyntactic variables are shown with
angle brackets, for example:

```
    ..., type rm <filename>
```

However, that is not the style that Texinfo uses. (You can, of course,
modify the sources to TeX and the Info formatting commands to output
the <...> format if you wish.)

1.106 texi.info/file

```
 @file {file-name }
-------------------
```

   Use the @file command to indicate text that is the name of a file,
buffer, or directory, or is the name of a node in Info. You can also
use the command for file name suffixes. Do not use @file for symbols
in a programming language; use @code.

   Currently, @file is equivalent to @samp in its effects. For
example,

```
    The @file{.el} files are in
    the @file{/gnu/emacs/lisp} directory.
```

produces

```
    The .el files are in the /gnu/emacs/lisp directory.
```

1.107 texi.info/dfn

```
 @dfn {term }
-------------
```

   Use the @dfn command to identify the introductory or defining use
of a technical term. Use the command only in passages whose purpose is
to introduce a term which will be used again or which the reader ought
to know. Mere passing mention of a term for the first time does not
deserve @dfn. The command generates italics in the printed manual,
and double quotation marks in the Info file. For example:

```
    Getting rid of a file is called @dfn{deleting} it.
```

produces

```
    Getting rid of a file is called deleting it.
```

   As a general rule, a sentence containing the defining occurrence of a
term should be a definition of the term. The sentence does not need to
say explicitly that it is a definition, but it should contain the
information of a definition--it should make the meaning clear.

1.108 texi.info/cite

```
                @cite {reference }
```
_____

   Use the @cite command for the name of a book that lacks a companion
Info file. The command produces italics in the printed manual, and
quotation marks in the Info file.

   (If a book is written in Texinfo, it is better to use a cross
reference command since a reader can easily follow such a reference in
Info. See
                @xref
                .)

1.109   texi.info/Emphasis

```
                Emphasizing Text
```
================

   Usually, Texinfo changes the font to mark words in the text
according to what category the words belong to; an example is the
However, sometimes you will want to emphasize text without indicating a
category. Texinfo has two commands to do this. Also, Texinfo has
several commands that specify the font in which TeX will typeset text.
These commands have no affect on Info and only one of them, the @r
command, has any regular use.

                emph & strong
                               How to emphasize text in Texinfo.

                Smallcaps
                                 How to use the small caps font.

                Fonts
                                  Various font commands for printed output.

1.110   texi.info/emph & strong

```
 @emph {text } and  @strong {text }
```

   The @emph and @strong commands are for emphasis; @strong is
stronger. In printed output, @emph produces italics and @strong
produces bold.

   For example,

_____

```
    @quotation
    @strong{Caution:} @code{rm * .[^.]*} removes @emph{all}
    files in the directory.
    @end quotation
```

produces:

```
        *Caution*: `rm * .[^.]*' removes *all*
        files in the directory.
```

   The @strong command is seldom used except to mark what is, in
effect, a typographical element, such as the word `Caution' in the
preceding example.

   In the Info file, both @emph and @strong put asterisks around the
text.

        Caution: Do not use @emph or @strong with the word Note; Info
        will mistake the combination for a cross reference. Use a phrase
        such as Please note or Caution instead.

1.111   texi.info/Smallcaps

 @sc {text }: The Small Caps Font

   Use the @sc command to set text in the printed output in a small
caps font and set text in the Info file in upper case letters.

   Write the text between braces in lower case, like this:

        The @sc{acm} and @sc{ieee} are technical societies.

This produces:

        The ACM and IEEE are technical societies.

   TeX typesets the small caps font in a manner that prevents the
letters from `jumping out at you on the page'. This makes small caps
text easier to read than text in all upper case. The Info formatting
commands set all small caps text in upper case.

   If the text between the braces of an @sc command is upper case, TeX
typesets in full-size capitals. Use full-size capitals sparingly.

   You may also use the small caps font for a jargon word such as ATO
(a NASA word meaning `abort to orbit').

   There are subtleties to using the small caps font with a jargon word
such as CDR, a word used in Lisp programming. In this case, you should
use the small caps font when the word refers to the second and
subsequent elements of a list (the CDR of the list), but you should use
 @code when the word refers to the Lisp function of the same spelling.

1.112   texi.info/Fonts

```
Fonts for Printing, Not Info
----------------------------
```

   Texinfo provides four font commands that specify font changes in the
printed manual but have no effect in the Info file.   @i requests
italic font (in some versions of TeX, a slanted font is used), @b
requests bold face, @t requests the fixed-width, typewriter-style font
used by @code, and @r requests a roman font, which is the usual font
in which text is printed. All four commands apply to an argument that
follows, surrounded by braces.

   Only the @r command has much use: in example programs, you can use
the @r command to convert code comments from the fixed-width font to a
roman font. This looks better in printed output.

   For example,

```
      @lisp
      (+ 2 2)     ; @r{Add two plus two.}
      @end lisp
```

produces

```
      (+ 2 2)     ; Add two plus two.
```

   If possible, you should avoid using the other three font commands.
If you need to use one, it probably indicates a gap in the Texinfo
language.

1.113   texi.info/Quotations and Examples

```
                Quotations and Examples
**********************
```

   Quotations and examples are blocks of text consisting of one or more
whole paragraphs that are set off from the bulk of the text and treated
differently. They are usually indented.

   In Texinfo, you always begin a quotation or example by writing an
an @end command that is also at the beginning of a line by itself.
For instance, you begin an example by writing @example by itself at
the beginning of a line and end the example by writing @end example on
a line by itself, at the beginning of that line.

```
                Block Enclosing Commands
```

1.114   texi.info/Block Enclosing Commands

                    The Block Enclosing Commands
============================

   Here are commands for quotations and examples:

 @quotation
     Indicate text that is quoted. The text is filled, indented, and
     printed in a roman font by default.

 @example
     Illustrate code, commands, and the like. The text is printed in a
     fixed-width font, and indented but not filled.

 @lisp
     Illustrate Lisp code. The text is printed in a fixed-width font,

and indented but not filled.

@smallexample
Illustrate code, commands, and the like. Similar to @example, except that in TeX this command typesets text in a smaller font for the smaller @smallbook format than for the 8.5 by 11 inch format.

@smalllisp
Illustrate Lisp code. Similar to @lisp, except that in TeX this command typesets text in a smaller font for the smaller @smallbook format than for the 8.5 by 11 inch format.

@display
Display illustrative text. The text is indented but not filled, and no font is specified (so, by default, the font is roman).

@format
Print illustrative text. The text is not indented and not filled and no font is specified (so, by default, the font is roman).

The @exdent command is used within the above constructs to undo the indentation of a line.

The @flushleft and @flushright commands are used to line up the left or right margins of unfilled text.

The @noindent command may be used after one of the above constructs to prevent the following text from being indented as a new paragraph.

You can use the @cartouche command within one of the above constructs to highlight the example or quotation by drawing a box with rounded corners around it. (The @cartouche command affects only the printed manual; it has no effect in the Info file; see

                    Drawing Cartouches Around Examples
                    .)

1.115 texi.info/quotation

@quotation
===========

The text of a quotation is processed normally except that:

* the margins are closer to the center of the page, so the whole of the quotation is indented;

* the first lines of paragraphs are indented no more than other lines;

* in the printed output, interparagraph spacing is reduced.

       This is an example of text written between an @quotation command
       and an @end quotation command. An @quotation command is most
       often used to indicate text that is excerpted from another (real
       or hypothetical) printed work.

   Write an @quotation command as text on a line by itself. This line
will disappear from the output. Mark the end of the quotation with a
line beginning with and containing only @end quotation. The @end
quotation line will likewise disappear from the output. Thus, the
following,

       @quotation
       This is
       a foo.
       @end quotation

produces

       This is a foo.

1.116   texi.info/example

                    @example
=========

   The @example command is used to indicate an example that is not
part of the running text, such as computer input or output.

       This is an example of text written between an
        @example command
       and an @end example command.
       The text is indented but not filled.

       In the printed manual, the text is typeset in a
       fixed-width font, and extra spaces and blank lines are
       significant. In the Info file, an analogous result is
       obtained by indenting each line with five spaces.

   Write an @example command at the beginning of a line by itself.
This line will disappear from the output. Mark the end of the example
with an @end example command, also written at the beginning of a line
by itself. The @end example will disappear from the output.

       For example,

       @example
       mv foo bar
       @end example

produces

       mv foo bar

   Since the lines containing @example and @end example will

disappear, you should put a blank line before the @example and another
blank line after the @end example. (Remember that blank lines between
the beginning @example and the ending @end example will appear in the
output.)

     Caution: Do not use tabs in the lines of an example (or anywhere
     else in Texinfo, for that matter)! TeX treats tabs as single
     spaces, and that is not what they look like. This is a problem
     with TeX. (If necessary, in Emacs, you can use M-x untabify to
     convert tabs in a region to multiple spaces.)

   Examples are often, logically speaking, "in the middle" of a
paragraph, and the text continues after an example should not be
indented. The @noindent command prevents a piece of text from being
indented as if it were a new paragraph. (See
                 noindent
                 .)

   (The @code command is used for examples of code that are embedded
within sentences, not set off from preceding and following text. See

                 @code
                 .)

1.117 texi.info/noindent

                 @noindent
==========

   An example or other inclusion can break a paragraph into segments.
Ordinarily, the formatters indent text that follows an example as a new
paragraph. However, you can prevent this by writing @noindent at the
beginning of a line by itself preceding the continuation text.

   For example:

     @example
     This is an example
     @end example

     @noindent
     This line is not indented. As you can see, the
     beginning of the line is fully flush left with the line
     that follows after it. (This whole example is between
     @code{@@display} and @code{@@end display}.)

produces

          This is an example

     This line is not indented. As you can see, the
     beginning of the line is fully flush left with the line

    that follows after it. (This whole example is between
     @display and @end display.)

   To adjust the number of blank lines properly in the Info file output,
remember that the line containing @noindent does not generate a blank
line, and neither does the @end example line.

   In the Texinfo source file for this manual, each line that says
'produces' is preceded by a line containing @noindent.

   Do not put braces after an @noindent command; they are not
necessary, since @noindent is a command used outside of paragraphs
(see

                Command Syntax
).

1.118   texi.info/Lisp Example

 @lisp
======

   The @lisp command is used for Lisp code. It is synonymous with the
 @example command.

     This is an example of text written between an
      @lisp command and an @end lisp command.

   Use @lisp instead of @example so as to preserve information
regarding the nature of the example. This is useful, for example, if
you write a function that evaluates only and all the Lisp code in a
Texinfo file. Then you can use the Texinfo file as a Lisp library.(1)

   Mark the end of @lisp with @end lisp on a line by itself.

   ---------- Footnotes ----------

   (1) It would be straightforward to extend Texinfo to work in a
similar fashion for C, FORTRAN, or other languages.

1.119   texi.info/smallexample & smalllisp

 @smallexample and @smalllisp
==============================

   In addition to the regular @example and @lisp commands, Texinfo
has two other "example-style" commands. These are the @smallexample
and @smalllisp commands. Both these commands are designed for use
with the @smallbook command that causes TeX to produce a printed
manual in a 7 by 9.25 inch format rather than the regular 8.5 by 11

inch format.

   In TeX, the @smallexample and @smalllisp commands typeset text in
a smaller font for the smaller @smallbook format than for the 8.5 by
11 inch format. Consequently, many examples containing long lines fit
in a narrower, @smallbook page without needing to be shortened. Both
commands typeset in the normal font size when you format for the 8.5 by
11 inch size; indeed, in this situation, the @smallexample and
   In Info, the @smallexample and @smalllisp commands are equivalent
to the @example and @lisp commands, and work exactly the same.

   Mark the end of @smallexample or @smalllisp with @end
smallexample or @end smalllisp, respectively.

     This is an example of text written between @smallexample and
      @end smallexample. In Info and in an 8.5 by 11 inch manual,
     this text appears in its normal size; but in a 7 by 9.25 inch manual,
     this text appears in a smaller font.

   The @smallexample and @smalllisp commands make it easier to
prepare smaller format manuals without forcing you to edit examples by
hand to fit them onto narrower pages.

   As a general rule, a printed document looks better if you write all
the examples in a chapter consistently in @example or in
   See Printing , for more information about the

1.120   texi.info/display

 @display
=========

   The @display command begins a kind of example. It is like the
select the fixed-width font. In fact, it does not specify the font at
all, so that the text appears in the same font it would have appeared
in without the @display command.

     This is an example of text written between an @display command
     and an @end display command. The @display command
     indents the text, but does not fill it.

1.121   texi.info/format

 @format
========

   The @format command is similar to @example except that, in the
printed manual, @format does not select the fixed-width font and does
not narrow the margins.

This is an example of text written between an   @format command

and an @end format command. As you can see
from this example,
the @format command does not fill the text.

1.122   texi.info/exdent

 @exdent: Undoing a Line's Indentation
=======================================

    The @exdent command removes any indentation a line might have. The
command is written at the beginning of a line and applies only to the
text that follows the command that is on the same line. Do not use
braces around the text. In a printed manual, the text on an @exdent
line is printed in the roman font.

    @exdent is usually used within examples. Thus,

      @example
      This line follows an @@example command.
      @exdent This line is exdented.
      This line follows the exdented line.
      The @@end example comes on the next line.
      @end group

produces

      This line follows an @example command.
This line is exdented.
      This line follows the exdented line.
      The @end example comes on the next line.

    In practice, the @exdent command is rarely used. Usually, you
un-indent text by ending the example and returning the page to its
normal width.

1.123   texi.info/flushleft & flushright

 @flushleft and @flushright
============================

    The @flushleft and @flushright commands line up the ends of lines
on the left and right margins of a page, but do not fill the text. The
commands are written on lines of their own, without braces. The
   For example,

      @flushleft
      This text is
      written flushleft.
      @end flushleft

produces

```
    This text is
    written flushleft.
```

   Flushright produces the type of indentation often used in the return
address of letters.

For example,

```
    @flushright
    Here is an example of text written
    flushright.  The @code{@flushright} command
    right justifies every line but leaves the
    left end ragged.
    @end flushright
```

produces

```
                              Here is an example of text written
                    flushright.  The  @flushright command
                        right justifies every line but leaves the
                                              left end ragged.
```

1.124   texi.info/cartouche

```
Drawing Cartouches Around Examples
==================================
```

   In a printed manual, the @cartouche command draws a box with
rounded corners around its contents. You can use this command to
further highlight an example or quotation. For instance, you could
write a manual in which one type of example is surrounded by a cartouche
for emphasis.

   The @cartouche command affects only the printed manual; it has no
effect in the Info file.

   For example,

```
    @example
    @cartouche
    % pwd
    /gnu/lib/emacs/info
    @end cartouche
    @end example
```

surrounds the two-line example with a box with rounded corners, in the
printed manual.

1.125 texi.info/Lists and Tables

                    Making Lists and Tables
****

   Texinfo has several ways of making lists and two-column tables.
Lists can be bulleted or numbered, while two-column tables can
highlight the items in the first column.

                   Introducing Lists
                          Texinfo formats lists for you.

                   itemize
                                   How to construct a simple list.

                   enumerate
                                   How to construct a numbered list.

                   Two-column Tables
                          How to construct a two-column table.

1.126 texi.info/Introducing Lists

Introducing Lists
=================

   Texinfo automatically indents the text in lists or tables, and
numbers an enumerated list. This last feature is useful if you modify
the list, since you do not need to renumber it yourself.

   Numbered lists and tables begin with the appropriate @-command at the
beginning of a line, and end with the corresponding @end command on a
line by itself. The table and itemized-list commands also require that
you write formatting information on the same line as the beginning
   Begin an enumerated list, for example, with an @enumerate command
and end the list with an @end enumerate command. Begin an itemized
list with an @itemize command, followed on the same line by a
formatting command such as @bullet, and end the list with an @end
itemize command.

   Precede each element of a list with an @item or @itemx command.

Here is an itemized list of the different kinds of table and lists:

   * Itemized lists with and without bullets.

   * Enumerated lists, using numbers or letters.

   * Two-column tables with highlighting.

Here is an enumerated list with the same items:

  1. Itemized lists with and without bullets.

  2. Enumerated lists, using numbers or letters.

  3. Two-column tables with highlighting.

And here is a two-column table with the same items and their @-commands:

 @itemize
     Itemized lists with and without bullets.

 @enumerate
     Enumerated lists, using numbers or letters.

 @table
 @ftable
 @vtable
     Two-column tables with highlighting.

1.127   texi.info/itemize

```
Making an Itemized List
=======================
```

   The @itemize command produces sequences of indented paragraphs,
with a bullet or other mark inside the left margin at the beginning of
each paragraph for which such a mark is desired.

   Begin an itemized list by writing @itemize at the beginning of a
line. Follow the command, on the same line, with a character or a
Texinfo command that generates a mark. Usually, you will write
or any special symbol that results in a single character in the Info
file. (When you write @bullet or @minus after an @itemize command,
you may omit the {}.)

   Write the text of the indented paragraphs themselves after the
   Before each paragraph for which a mark in the margin is desired,
write a line that says just @item. Do not write any other text on this
line.

   Usually, you should put a blank line before an @item. This puts a
blank line in the Info file. (TeX inserts the proper interline
whitespace in either case.) Except when the entries are very brief,
these blank lines make the list look better.

   Here is an example of the use of @itemize, followed by the output
it produces. Note that @bullet produces an * in Info and a round dot
in TeX.

```
     @itemize @bullet
     @item
     Some text for foo.
```

```
        @item
        Some text
        for bar.
        @end itemize
```

This produces:

        * Some text for foo.

        * Some text for bar.

   Itemized lists may be embedded within other itemized lists. Here is
a list marked with dashes embedded in a list marked with bullets:

```
        @itemize @bullet
        @item
        First item.

        @itemize @minus
        @item
        Inner item.

        @item
        Second inner item.
        @end itemize

        @item
        Second outer item.
        @end itemize
```

This produces:

        * First item.

            - Inner item.

            - Second inner item.

        * Second outer item.

1.128 texi.info/enumerate

                  Making a Numbered or Lettered List
==================================

   @enumerate is like @itemize except that the marks in the left
margin contain successive integers or letters. (See
                @itemize
                .)

   Write the @enumerate command at the beginning of a line. The
command does not require an argument, but accepts either a number or a
letter as an option. Without an argument, @enumerate starts the list

with the number 1. With a numeric argument, such as 3, the command
starts the list with that number. With an upper or lower case letter,
such as a or A, the command starts the list with that letter.

   Write the text of the enumerated list in the same way you write an
itemized list: put @item on a line of its own before the start of each
paragraph that you want enumerated. Do not write any other text on the
line beginning with @item.

   You should put a blank line between entries in the list. This
generally makes it easier to read the Info file.

   Here is an example of @enumerate without an argument:

      @enumerate
      @item
      Underlying causes.

      @item
      Proximate causes.
      @end enumerate

This produces:

  1. Underlying causes.

  2. Proximate causes.

   Here is an example with an argument of 3:

      @enumerate 3
      @item
      Predisposing causes.

      @item
      Precipitating causes.

      @item
      Perpetuating causes.
      @end enumerate

This produces:

  3. Predisposing causes.

  4. Precipitating causes.

  5. Perpetuating causes.

   Here is a brief summary of the alternatives. The summary is
constructed using @enumerate with an argument of a.

   a.   @enumerate

      Without an argument, produce a numbered list, starting with the
      number 1.

   b.   @enumerate positive-integer

      With a (positive) numeric argument, start a numbered list with that
      number. You can use this to continue a list that you interrupted
      with other text.

   c.   @enumerate upper-case-letter

      With an upper case letter as argument, start a list in which each
      item is marked by a letter, beginning with that upper case letter.

   d.   @enumerate lower-case-letter

      With a lower case letter as argument, start a list in which each
      item is marked by a letter, beginning with that lower case letter.

    You can also nest enumerated lists, as in an outline.

1.129 texi.info/Two-column Tables

                   Making a Two-column Table
==========================

    @table is similar to @itemize, but the command allows you to
specify a name or heading line for each item. (See
              @itemize
              .) The
useful for glossaries and explanatory exhibits.

                 table

                                       How to construct a two-column table.

                 ftable vtable

                              How to construct a two-column table
                                with automatic indexing.

                 itemx

                                       How to put more entries in the first ←
                                         column.

1.130 texi.info/table

                   Using the @table Command

   Use the @table command to produce two-column tables.

Write the @table command at the beginning of a line and follow it
on the same line with an argument that is a Texinfo command such as
followed by arguments in braces, in this case you use the command name
without an argument because @item will supply the argument. This
command will be applied to the text that goes into the first column of
each item and determines how it will be highlighted. For example,
 @samp command.

   You may also choose to use the @asis command as an argument to
after @table, TeX and the Info formatting commands output the first
column entries without added highlighting ('as is').

   (The @table command may work with other commands besides those
listed here. However, you can only use commands that normally take
arguments in braces.)

   Begin each table entry with an @item command at the beginning of a
line. Write the first column text on the same line as the @item
command. Write the second column text on the line following the @item
line and on subsequent lines. (You do not need to type anything for an
empty second column entry.) You may write as many lines of supporting
text as you wish, even several paragraphs. But only text on the same
line as the @item will be placed in the first column.

   Normally, you should put a blank line before an @item line. This
puts a blank like in the Info file. Except when the entries are very
brief, a blank line looks better.

   The following table, for example, highlights the text in the first
column with an   @samp command:

```
    @table @samp
    @item foo
    This is the text for
    @samp{foo}.

    @item bar
    Text for @samp{bar}.
    @end table
```

This produces:

foo
    This is the text for foo.

bar
    Text for bar.

   If you want to list two or more named items with a single block of
text, use the @itemx command. (See
                  @itemx
                   .)

1.131 texi.info/ftable vtable

                    @ftable and @vtable

    The @ftable and @vtable commands are the same as the @table
command except that @ftable automatically enters each of the items in
the first column of the table into the index of functions and @vtable
automatically enters each of the items in the first column of the table
into the index of variables. This simplifies the task of creating
indices. Only the items on the same line as the @item commands are
indexed, and they are indexed in exactly the form that they appear on
that line. See
                    Creating Indices
                    , for more information about indices.

    Begin a two-column table using @ftable or @vtable by writing the
argument that is a Texinfo command such as @code, exactly as you would
for an @table command; and end the table with an @end ftable or @end
vtable command on a line by itself.

1.132 texi.info/itemx

 @itemx

    Use the @itemx command inside a table when you have two or more
first column entries for the same item, each of which should appear on
a line of its own. Use @itemx for all but the first entry. The
generate extra vertical space above the first column text.

    For example,

        @table @code
        @item upcase
        @itemx downcase
        These two functions accept a character or a string as
        argument, and return the corresponding upper case (lower
        case) character or string.
        @end table

This produces:

upcase
downcase
        These two functions accept a character or a string as argument,
        and return the corresponding upper case (lower case) character or
        string.

(Note also that this example illustrates multi-line supporting text in
a two-column table.)

1.133 texi.info/Indices

```
              Creating Indices
****************
```

   Using Texinfo, you can generate indices without having to sort and
collate entries manually. In an index, the entries are listed in
alphabetical order, together with information on how to find the
discussion of each entry. In a printed manual, this information
consists of page numbers. In an Info file, this information is a menu
entry leading to the first node referenced.

   Texinfo provides several predefined kinds of index: an index for
functions, an index for variables, an index for concepts, and so on.
You can combine indices or use them for other than their canonical
purpose. If you wish, you can define your own indices.

```
              Index Entries
                        Choose different words for index entries.

              Predefined Indices
                    Use different indices for different kinds
                         of entry.

              Indexing Commands
                     How to make an index entry.

              Combining Indices

                        How to define your own indices.
```

1.134 texi.info/Index Entries

```
              Making Index Entries
====================
```

   When you are making index entries, it is good practice to think of
the different ways people may look for something. Different people do
not think of the same words when they look something up. A helpful
index will have items indexed under all the different words that people
may use. For example, one reader may think it obvious that the
two-letter names for indices should be listed under "Indices,
two-letter names", since the word "Index" is the general concept. But
another reader may remember the specific concept of two-letter names
and search for the entry listed as "Two letter names for indices". A
good index will have both entries and will help both readers.

   Like typesetting, the construction of an index is a highly skilled,

professional art, the subtleties of which are not appreciated until you
need to do it yourself.

    See
                Printing Indices & Menus
                , for information about printing an index
at the end of a book or creating an index menu in an Info file.

1.135   texi.info/Predefined Indices

                Predefined Indices
==================

    Texinfo provides six predefined indices:

  * A concept index listing concepts that are discussed.

  * A function index listing functions (such as entry points of
    libraries).

  * A variables index listing variables (such as global variables of
    libraries).

  * A keystroke index listing keyboard commands.

  * A program index listing names of programs.

  * A data type index listing data types (such as structures defined in
    header files).

Not every manual needs all of these, and most manuals use two or three
of them. This manual has two indices: a concept index and an @-command
index (that is actually the function index but is called a command
index in the chapter heading). Two or more indices can be combined
into one using the @synindex or @syncodeindex commands. See

                Combining Indices
                .

1.136   texi.info/Indexing Commands

                Defining the Entries of an Index
================================

    The data to make an index come from many individual indexing commands
scattered throughout the Texinfo source file. Each command says to add
one entry to a particular index; after formatting, the index will give
the current page number or node name as the reference.

An index entry consists of an indexing command at the beginning of a
line followed, on the rest of the line, by the entry.

For example, this section begins with the following five entries for
the concept index:

```
@cindex Defining indexing entries
@cindex Index entries
@cindex Entries for an index
@cindex Specifying index entries
@cindex Creating index entries
```

Each predefined index has its own indexing command-- @cindex for the
concept index, @findex for the function index, and so on.

The usual convention is to capitalize the first word of each index
entry, unless that word is the name of a function, variable, or other
such entity that should not be capitalized. Thus, if you are
documenting Emacs Lisp, you should usually capitalize entries in the
concept index, but not those in the function index. However, if your
concept index entries are consistently short (one or two words each) it
may look better for each regular entry to start with a lower case
letter. Whichever convention you adapt, please be consistent!

By default, entries for a concept index are printed in a small roman
font and entries for the other indices are printed in a small @code
font. You may change the way part of an entry is printed with the
usual Texinfo commands, such as @file for file names and @emph for
emphasis (see
                    Marking Text
).

The six indexing commands for predefined indices are:

@cindex concept
    Make an entry in the concept index for concept.

@findex function
    Make an entry in the function index for function.

@vindex variable
    Make an entry in the variable index for variable.

@kindex keystroke
    Make an entry in the key index for keystroke.

@pindex program
    Make an entry in the program index for program.

@tindex data type
    Make an entry in the data type index for data type.

    Caution: Do not use a colon in an index entry. In Info, a colon
    separates the menu entry name from the node name. An extra colon
    confuses Info. See
                    The Parts of a Menu

                         , for more information
       about the structure of a menu entry.

   If you write several identical index entries in different places in a
Texinfo file, the index in the printed manual will list all the pages to
which those entries refer. However, the index in the Info file will
list only the node that references the first of those index entries.
Therefore, it is best to write indices in which each entry refers to
only one place in the Texinfo file. Fortunately, this constraint is a
feature rather than a loss since it means that the index will be easy
to use. Otherwise, you could create an index that lists several pages
for one entry and your reader would not know to which page to turn. If
you have two identical entries for one topic, change the topics
slightly, or qualify them to indicate the difference.

   You are not actually required to use the predefined indices for their
canonical purposes. For example, suppose you wish to index some C
preprocessor macros. You could put them in the function index along
with actual functions, just by writing @findex commands for them;
then, when you print the "Function Index" as an unnumbered chapter, you
could give it the title 'Function and Macro Index' and all will be
consistent for the reader. Or you could put the macros in with the
data types by writing @tindex commands for them, and give that index a
suitable title so the reader will understand. (See

                    Printing Indices & Menus
                    .)

1.137   texi.info/Combining Indices

                    Combining Indices
==================

   Sometimes you will want to combine two disparate indices such as
functions and concepts, perhaps because you have few enough of one of
them that a separate index for them would look silly.

   You could put functions into the concept index by writing @cindex
commands for them instead of @findex commands, and produce a
consistent manual by printing the concept index with the title
'Function and Concept Index' and not printing the 'Function Index' at
all; but this is not a robust procedure. It works only if your
document is never included as part of another document that is designed
to have a separate function index; if your document were to be included
with such a document, the functions from your document and those from
the other would not end up together. Also, to make your function names
appear in the right font in the concept index, you would need to
enclose every one of them between the braces of @code.

              syncodeindex
                                How to merge two indices, using @code

                                             font for the merged-from index.

                    synindex

                                        How to merge two indices, using the
                              default font of the merged-to index.

1.138 texi.info/syncodeindex

 @syncodeindex
....

   When you want to combine functions and concepts into one index, you
should index the functions with @findex and index the concepts with
index entries into the concept index.

   The @syncodeindex command takes two arguments; they are the name of
the index to redirect, and the name of the index to redirect it to.
The template looks like this:

     @syncodeindex from to

   For this purpose, the indices are given two-letter names:

cp
     concept index

fn
     function index

vr
     variable index

ky
     key index

pg
     program index

tp
     data type index

   Write an @syncodeindex command before or shortly after the
end-of-header line at the beginning of a Texinfo file. For example, to
merge a function index with a concept index, write the following:

     @syncodeindex fn cp

This will cause all entries designated for the function index to merge
in with the concept index instead.

   To merge both a variables index and a function index into a concept
index, write the following:

```
     @syncodeindex vr cp
     @syncodeindex fn cp
```

   The @syncodeindex command puts all the entries from the 'from'
index (the redirected index) into the @code font, overriding whatever
default font is used by the index to which the entries are now
directed. This way, if you direct function names from a function index
into a concept index, all the function names are printed in the @code
font as you would expect.

1.139   texi.info/synindex

                    @synindex
....

   The @synindex command is nearly the same as the @syncodeindex
command, except that it does not put the 'from' index entries into the
 @code font; rather it puts them in the roman font. Thus, you use
   See
                    Printing Indices & Menus
                    , for information about printing an index
at the end of a book or creating an index menu in an Info file.

1.140   texi.info/New Indices

                    Defining New Indices
====================

   In addition to the predefined indices, you may use the @defindex
and @defcodeindex commands to define new indices. These commands
create new indexing @-commands with which you mark index entries. The
   @defindex name

   The name of an index should be a two letter word, such as au. For
example:

     @defindex au

   This defines a new index, called the au index. At the same time, it
creates a new indexing command, @auindex, that you can use to make
index entries. Use the new indexing command just as you would use a
predefined indexing command.

   For example, here is a section heading followed by a concept index
entry and two au index entries.

     @section Cognitive Semantics
     @cindex kinesthetic image schemas
     @auindex Johnson, Mark

```
     @auindex Lakoff, George
```

(Evidently, au serves here as an abbreviation for "author".) Texinfo
constructs the new indexing command by concatenating the name of the
index with index; thus, defining an au index leads to the automatic
creation of an @auindex command.

   Use the @printindex command to print the index, as you do with the
predefined indices. For example:

```
     @node Author Index, Subject Index, , Top
     @unnumbered Author Index

     @printindex au
```

   The @defcodeindex is like the @defindex command, except that, in
the printed output, it prints entries in an @code font instead of a
roman font. Thus, it parallels the @findex command rather than the
   You should define new indices within or right after the end-of-header
line of a Texinfo file, before any @synindex or @syncodeindex
commands (see
                 Header
).

1.141   texi.info/Insertions

                  Special Insertions
****

   Texinfo provides several commands for formatting dimensions, for
inserting single characters that have special meaning in Texinfo, such
as braces, and for inserting special graphic symbols that do not
correspond to characters, such as dots and bullets.

                  Braces Atsigns Periods
                        How to insert braces, @ and periods.

                  dmn
                                         How to format a dimension.

                  Dots Bullets
                                  How to insert dots and bullets.

                  TeX and copyright
                          How to insert the TeX logo
                              and the copyright symbol.

                  minus
                                  How to insert a minus sign.
```

## 1.142 texi.info/Braces Atsigns Periods

```
                  Inserting  @, Braces, and Periods
==================================
```

   @ and curly braces are special characters in Texinfo. To insert
these characters so they appear in text, you must put an @ in front of
these characters to prevent Texinfo from misinterpreting them.

   Periods are also special. Depending on whether the period is inside
or at the end of a sentence, less or more space is inserted after a
period in a typeset manual. Since it is not always possible for
Texinfo to determine when a period ends a sentence and when it is used
in an abbreviation, special commands are needed in some circumstances.
(Usually, Texinfo can guess how to handle periods, so you do not need
to use the special commands; you just enter a period as you would if
you were using a typewriter, which means you put two spaces after the
period, question mark, or exclamation mark that ends a sentence.)

   Do not put braces after any of these commands; they are not
necessary.

```
                  Inserting An Atsign

                  Inserting Braces
                           How to insert { and }

                  Controlling Spacing
                        How to insert the right amount of space
                                 after punctuation within a sentence.
```

1.143 texi.info/Inserting An Atsign

```
Inserting  @ with @@
--------------------
```

   @@ stands for a single @ in either printed or Info output.

   Do not put braces after an @@ command.

1.144 texi.info/Inserting Braces

```
Inserting { and }with @{ and @}
-------------------------------
```

   stands for a single { in either printed or Info output.

  @} stands for a single } in either printed or Info output.

   Do not put braces after either an   or an   @} command.

1.145 texi.info/Controlling Spacing

```
Spacing After Colons and Periods
--------------------------------
```

   Use the @: command after a period, question mark, exclamation
mark, or colon that should not be followed by extra space.   For
example, use @: after periods that end abbreviations which are not at
the ends of sentences.   @: has no effect on the Info file output.

   For example,

     The s.o.p.@: has three parts ...
     The s.o.p. has three parts ...

produces

     The s.o.p. has three parts ...
     The s.o.p. has three parts ...

 @: has no effect on the Info output. (s.o.p is an acronym for
"Standard Operating Procedure".)

   Use @. instead of a period at the end of a sentence that ends with
a single capital letter. Otherwise, TeX will think the letter is an
abbreviation and will not insert the correct end-of-sentence spacing.
Here is an example:

     Give it to M.I.B. and to M.E.W@. Also, give it to R.J.C@.
     Give it to M.I.B. and to M.E.W. Also, give it to R.J.C.

produces

     Give it to M.I.B. and to M.E.W. Also, give it to R.J.C.
     Give it to M.I.B. and to M.E.W. Also, give it to R.J.C.

   In the Info file output, @. is equivalent to a simple ..

   The meanings of @: and @. in Texinfo are designed to work well
with the Emacs sentence motion commands. This made it necessary for
them to be incompatible with some other formatting systems that use
   Do not put braces after either an @: or an @. command.

1.146   texi.info/dmn

```
                    @dmn {dimension }: Format a Dimension
========================================
```

   At times, you may want to write 12pt or 8.5in with little or no
space between the number and the abbreviation for the dimension. You
can use the @dmn command to do this. On seeing the command, TeX
inserts just enough space for proper typesetting; the Info formatting
commands insert no space at all, since the Info file does not require
it.

   To use the @dmn command, write the number and then follow it
immediately, with no intervening space, by @dmn, and then by the
dimension within braces.

For example,

     A4 paper is 8.27@dmn{in} wide.

produces

     A4 paper is 8.27in wide.

   Not everyone uses this style. Instead of writing 8.27@dmn{in} in
the Texinfo file, you may write 8.27 in. or 8.27 inches. (In these
cases, the formatters may insert a line break between the number and the
dimension. Also, if you write a period after an abbreviation within a
sentence, you should write @: after the period to prevent TeX from
inserting extra whitespace. See
                    Spacing After Colons and Periods
                    .)

1.147   texi.info/Dots Bullets

```
                    Inserting Ellipsis, Dots, and Bullets
========================================
```

   An ellipsis (a line of dots) is not typeset as a string of periods,
so a special command is used for ellipsis in Texinfo. The @bullet
command is special, too. Each of these commands is followed by a pair
of braces, {}, without any whitespace between the name of the command
and the braces. (You need to use braces with these commands because
you can use them next to other text; without the braces, the formatters
would be confused. See
                    @-Command Syntax
                    , for further information.)

```
                    dots
                                        How to insert dots ...
```

1.148   texi.info/dots

```
@dots {}
---------
```

Use the @dots{} command to generate an ellipsis, which is three
dots in a row, appropriately spaced, like this: '...'. Do not simply
write three periods in the input file; that would work for the Info
file output, but would produce the wrong amount of space between the
periods in the printed manual.

1.149   texi.info/bullet

```
                @bullet {}
-----------
```

Use the @bullet{} command to generate a large round dot, or the
closest possible thing to one. In Info, an asterisk is used.

Here is a bullet: *

When you use @bullet in @itemize, you do not need to type the
braces, because @itemize supplies them. See
                itemize
                .

1.150   texi.info/TeX and copyright

```
                Inserting TeX and the Copyright Symbol
======================================
```

The logo 'TeX' is typeset in a special fashion and it needs an
these commands is followed by a pair of braces, {}, without any
whitespace between the name of the command and the braces.

```
                         How to use  @copyright {}.
```

1.151 texi.info/tex

```
 @TeX {}
--------
```

   Use the @TeX{} command to generate 'TeX'. In a printed manual,
this is a special logo that is different from three ordinary letters.
In Info, it just looks like TeX. The @TeX{} command is unique among
Texinfo commands in that the T and the X are in upper case.

1.152 texi.info/copyright symbol

```
 @copyright {}
--------------
```

   Use the @copyright{} command to generate '(C)'. In a printed
manual, this is a c inside a circle, and in Info, this is (C).

1.153 texi.info/minus

```
               @minus {}: Inserting a Minus Sign
===================================
```

   Use the @minus{} command to generate a minus sign. In a
fixed-width font, this is a single hyphen, but in a proportional font,
the symbol is the customary length for a minus sign--a little longer
than a hyphen.

   You can compare the two forms:

     - is a minus sign generated with @minus{},

     '-' is a hyphen generated with the character -.

In the fixed-width font used by Info, @minus{} is the same as a hyphen.

   You should not use @minus{} inside @code or @example because the
width distinction is not made in the fixed-width font they use.

   When you use @minus to specify the mark beginning each entry in an
itemized list, you do not need to type the braces (see
                itemize
).

1.154   texi.info/Glyphs

```
                   Glyphs for Examples
*******************
```

   In Texinfo, code is often illustrated in examples that are delimited
by @example and @end example, or by @lisp and @end lisp. In such
examples, you can indicate the results of evaluation or an expansion
using => or ==>. Likewise, there are commands to insert glyphs to
indicate printed output, error messages, equivalence of expressions,
and the location of point.

   The glyph-insertion commands do not need to be used within an
example, but most often they are. Every glyph-insertion command is
followed by a pair of left- and right-hand braces.

                   Glyphs Summary

                   result
                                   How to show the result of expression.

                   expansion
                                 How to indicate an expansion.

                   Print Glyph
                             How to indicate printed output.

                   Error Glyph
                             How to indicate an error message.

                   Equivalence
                             How to indicate equivalence.

                   Point Glyph
                             How to indicate the location of point.

1.155   texi.info/Glyphs Summary

```
Glyphs Summary
==============
```

   Here are the different glyph commands:

```
=>
      @result{} points to the result of an expression.
```

```
==>
      @expansion{} shows the results of a macro expansion.

-|
      @print{} indicates printed output.

error-->
      @error{} indicates that the following text is an error message.

==
      @equiv{} indicates the exact equivalence of two forms.

-!-
      @point{} shows the location of point.
```

1.156 texi.info/result

```
=>: Indicating Evaluation
=========================
```

   Use the @result{} command to indicate the result of evaluating an
expression.

   The @result{} command is displayed as => in Info and as a double
stemmed arrow in the printed output.

   Thus, the following,

```
   (cdr '(1 2 3))
        => (2 3)
```

may be read as "(cdr '(1 2 3)) evaluates to (2 3)".

1.157 texi.info/expansion

```
==>: Indicating an Expansion
============================
```

   When an expression is a macro call, it expands into a new expression.
You can indicate the result of the expansion with the @expansion{}
command.

   The @expansion{} command is displayed as ==> in Info and as a long
arrow with a flat base in the printed output.

   For example, the following

```
   @lisp
   (third '(a b c))
        @expansion{} (car (cdr (cdr '(a b c))))
```

```
        @result{} c
     @end lisp
```

produces

```
     (third '(a b c))
          ==> (car (cdr (cdr '(a b c))))
          => c
```

which may be read as:

```
     (third '(a b c)) expands to (car (cdr (cdr '(a b c)))); the result
     of evaluating the expression is c.
```

Often, as in this case, an example looks better if the @expansion{}
and @result{} commands are indented five spaces.

1.158   texi.info/Print Glyph

-|: Indicating Printed Output
=============================

   Sometimes an expression will print output during its execution. You
can indicate the printed output with the @print{} command.

   The @print{} command is displayed as -| in Info and similarly, as a
horizontal dash butting against a vertical bar, in the printed output.

   In the following example, the printed text is indicated with -|, and
the value of the expression follows on the last line.

```
     (progn (print 'foo) (print 'bar))
          -| foo
          -| bar
          => bar
```

In a Texinfo source file, this example is written as follows:

```
     @lisp
     (progn (print 'foo) (print 'bar))
          @print{} foo
          @print{} bar
          @result{} bar
     @end lisp
```

1.159   texi.info/Error Glyph

error-->: Indicating an Error Message
=====================================

A piece of code may cause an error when you evaluate it. You can
designate the error message with the @error{} command.

   The @error{} command is displayed as error--> in Info and as the
word 'error' in a box in the printed output.

   Thus,

```
@lisp
(+ 23 'x)
@error{} Wrong type argument: integer-or-marker-p, x
@end lisp
```

produces

```
(+ 23 'x)
error--> Wrong type argument: integer-or-marker-p, x
```

This indicates that the following error message is printed when you
evaluate the expression:

```
Wrong type argument: integer-or-marker-p, x
```

   Note that error--> itself is not part of the error message.

1.160   texi.info/Equivalence

```
==: Indicating Equivalence
==========================
```

   Sometimes two expressions produce identical results. You can
indicate the exact equivalence of two forms with the @equiv{} command.

   The @equiv{} command is displayed as == in Info and as a three
parallel horizontal lines in the printed output.

   Thus,

```
@lisp
(make-sparse-keymap) @equiv{} (list 'keymap)
@end lisp
```

produces

```
(make-sparse-keymap) == (list 'keymap)
```

This indicates that evaluating (make-sparse-keymap) produces identical
results to evaluating (list 'keymap).

1.161   texi.info/Point Glyph

```
Indicating Point in a Buffer
============================
```

Sometimes you need to show an example of text in an Emacs buffer. In
such examples, the convention is to include the entire contents of the
buffer in question between two lines of dashes containing the buffer
name.

You can use the @point{} command to show the location of point in
the text in the buffer. (The symbol for point, of course, is not part
of the text in the buffer; it indicates the place between two
characters where point is located.)

The @point{} command is displayed as -!- in Info and as a small
five pointed star in the printed output.

The following example shows the contents of buffer foo before and
after evaluating a Lisp command to insert the word changed.

```
    ---------- Buffer: foo ----------
    This is the -!-contents of foo.
    ---------- Buffer: foo ----------

    (insert "changed ")
        => nil
    ---------- Buffer: foo ----------
    This is the changed -!-contents of foo.
    ---------- Buffer: foo ----------
```

In a Texinfo source file, the example is written like this:

```
    @example
    ---------- Buffer: foo ----------
    This is the @point{}contents of foo.
    ---------- Buffer: foo ----------

    (insert "changed ")
        @result{} nil
    ---------- Buffer: foo ----------
    This is the changed @point{}contents of foo.
    ---------- Buffer: foo ----------
    @end example
```

1.162 texi.info/Breaks

```
              Making and Preventing Breaks
****************************
```

Usually, a Texinfo file is processed both by TeX and by one of the
Info formatting commands. Line, paragraph, or page breaks sometimes
occur in the 'wrong' place in one or other form of output. You must
ensure that text looks right both in the printed manual and in the Info
file.

   For example, in a printed manual, page breaks may occur awkwardly in
the middle of an example; to prevent this, you can hold text together
using a grouping command that keeps the text from being split across
two pages. Conversely, you may want to force a page break where none
would occur normally. Fortunately, problems like these do not often
arise. When they do, use the break, break prevention, or pagination
commands.

                    Break Commands
                              Cause and prevent splits.

                    Line Breaks
                                   How to force a single line to use two lines.

                    w
                                        How to prevent unwanted line breaks.

                    sp
                                      How to insert blank lines.

                    page
                                       How to force the start of a new page.

                    group
                                     How to prevent unwanted page breaks.

                    need
                                      Another way to prevent unwanted page ←
                                   breaks.

1.163   texi.info/Break Commands

The Break Commands
==================

   The break commands create line and paragraph breaks:

 @*
     Force a line break.

 @sp n
     Skip n blank lines.

   The line-break-prevention command holds text together all on one
line:

 @w{text }
     Prevent text from being split and hyphenated across two lines.

   The pagination commands apply only to printed output, since Info

files do not have pages.

```
@page
    Start a new page in the printed manual.

@group
    Hold text together that must appear on one printed page.

@need mils
    Start a new printed page if not enough space on this one.
```

1.164 texi.info/Line Breaks

```
@*: Generate Line Breaks
========================
```

The @* command forces a line break in both the printed manual and
in Info.

For example,

```
This line @* is broken @*in two places.
```

produces

```
This line
 is broken
in two places.
```

(Note that the space after the first @* command is faithfully carried
down to the next line.)

The @* command is often used in a file's copyright page:

```
This is edition 2.0 of the Texinfo documentation,@*
and is for ...
```

In this case, the @* command keeps TeX from stretching the line across
the whole page in an ugly manner.

    Please note: Do not write braces after an @* command; they are
    not needed.

    Do not write an @refill command at the end of a paragraph
    containing an @* command; it will cause the paragraph to be
    refilled after the line break occurs, negating the effect of the
    line break.

1.165 texi.info/w

```
 @w {text }: Prevent Line Breaks
=================================
```

   @w{text } outputs text and prohibits line breaks within text.

   You can use the @w command to prevent TeX from automatically
hyphenating a long name or phrase that accidentally falls near the end
of a line.

     You can copy GNU software from @w{@file{prep.ai.mit.edu}}.

produces

     You can copy GNU software from prep.ai.mit.edu.

   In the Texinfo file, you must write the @w command and its argument
(all the affected text) all on one line.

     Caution: Do not write an @refill command at the end of a
     paragraph containing an @w command; it will cause the paragraph
     to be refilled and may thereby negate the effect of the @w
     command.

1.166   texi.info/sp

```
 @sp n: Insert Blank Lines
==========================
```

   A line beginning with and containing only @sp n generates n blank
lines of space in both the printed manual and the Info file.   @sp also
forces a paragraph break. For example,

     @sp 2

generates two blank lines.

   The @sp command is most often used in the title page.

1.167   texi.info/page

```
 @page: Start a New Page
========================
```

   A line containing only @page starts a new page in a printed manual.
The command has no effect on Info files since they are not paginated.
An @page command is often used in the @titlepage section of a Texinfo
file to start the copyright page.

1.168   texi.info/group

@group: Prevent Page Breaks
===========================

   The @group command (on a line by itself) is used inside an
group, which will appear entirely on one page in the printed output.
The group is terminated by a line containing only @end group. These
two lines produce no output of their own, and in the Info file output
they have no effect at all.

   Although @group would make sense conceptually in a wide variety of
contexts, its current implementation works reliably only within
have in common is that each line of input produces a line of output.)
In other contexts, @group can cause anomalous vertical spacing.

   This formatting requirement means that you should write:

     @example
     @group
     ...
     @end group
     @end example

with the @group and @end group commands inside the @example and
   The @group command is most often used to hold an example together
on one page. In this Texinfo manual, more than 100 examples contain
text that is enclosed between @group and @end group.

   If you forget to end a group, you may get strange and unfathomable
error messages when you run TeX. This is because TeX keeps trying to
put the rest of the Texinfo file onto the one page and does not start
to generate error messages until it has processed considerable text.
It is a good rule of thumb to look for a missing @end group if you get
incomprehensible error messages in TeX.

1.169   texi.info/need

@need mils: Prevent Page Breaks
===============================

   A line containing only @need n starts a new page in a printed
manual if fewer than n mils (thousandths of an inch) remain on the
current page. Do not use braces around the argument n. The @need
command has no effect on Info files since they are not paginated.

   This paragraph is preceded by an @need command that tells TeX to
start a new page if fewer than 800 mils (eight-tenths inch) remain on
the page. It looks like this:

     @need 800
     This paragraph is preceded by ...

The @need command is useful for preventing orphans (single lines at
the bottoms of printed pages).

1.170   texi.info/Definition Commands

                    Definition Commands
****

The @deffn command and the other definition commands enable you to
describe functions, variables, macros, commands, user options, special
forms and other such artifacts in a uniform format.

In the Info file, a definition causes the entity
category--'Function', 'Variable', or whatever--to appear at the
beginning of the first line of the definition, followed by the entity's
name and arguments. In the printed manual, the command causes TeX to
print the entity's name and its arguments on the left margin and print
the category next to the right margin. In both output formats, the
body of the definition is indented. Also, the name of the entity is
entered into the appropriate index: @deffn enters the name into the
index of functions, @defvr enters it into the index of variables, and
so on.

A manual need not and should not contain more than one definition for
a given name. An appendix containing a summary should use @table
rather than the definition commands.

          Def Cmd Template
                    How to structure a description using a
                        definition command.

          Optional Arguments
                    How to handle optional and repeated arguments.

          deffnx
                        How to group two or more 'first' lines.

                    Conventions for writing definitions.

          Sample Function Definition

1.171   texi.info/Def Cmd Template

                    The Template for a Definition
============================

    The @deffn command is used for definitions of entities that
resemble functions. To write a definition using the @deffn command,
write the @deffn command at the beginning of a line and follow it on
the same line by the category of the entity, the name of the entity
itself, and its arguments (if any). Then write the body of the
definition on succeeding lines. (You may embed examples in the body.)
Finally, end the definition with an @end deffn command written on a
line of its own. (The other definition commands follow the same
format.)

    The template for a definition looks like this:

    @deffn category name arguments ...
    body-of-definition
    @end deffn

For example,

    @deffn Command forward-word count
    This command moves point forward @var{count} words
    (or backward if @var{count} is negative). ...
    @end deffn

produces

    – Command: forward-word count
        This function moves point forward count words (or backward if
        count is negative). ...

    Capitalize the category name like a title. If the name of the
category contains spaces, as in the phrase 'Interactive Command', write
braces around it. For example:

    @deffn {Interactive Command} isearch-forward
    ...
    @end deffn

Otherwise, the second word will be mistaken for the name of the entity.

    Some of the definition commands are more general than others. The
functions and the like--for entities that may take arguments. When you
use this command, you specify the category to which the entity belongs.
The @deffn command possesses three predefined, specialized
variations, @defun, @defmac, and @defspec, that specify the category
for you: "Function", "Macro", and "Special Form" respectively. The
variations for describing particular kinds of variables.

    The template for a specialized definition, such as @defun, is
similar to the template for a generalized definition, except that you
do not need to specify the category:

    @defun name arguments ...
    body-of-definition

```
    @end defun
```

Thus,

```
    @defun buffer-end flag
    This function returns @code{(point-min)} if @var{flag}
    is less than 1, @code{(point-max)} otherwise.
    ...
    @end defun
```

produces

```
    - Function: buffer-end flag
        This function returns (point-min) if flag is less than 1,
        (point-max) otherwise.  ...
```

See

                 Sample Function Definition
                 , for a more detailed example of a
function definition, including the use of @example inside the
definition.

   The other specialized commands work like @defun.

1.172   texi.info/Optional Arguments

```
Optional and Repeated Arguments
===============================
```

   Some entities take optional or repeated arguments, which may be
specified by a distinctive glyph that uses square brackets and
ellipses. For example, a special form often breaks its argument list
into separate arguments in more complicated ways than a straightforward
function.

   An argument enclosed within square brackets is optional. Thus,
[optional-arg] means that optional-arg is optional. An argument
followed by an ellipsis is optional and may be repeated more than once.
Thus, repeated-args ... stands for zero or more arguments. Parentheses
are used when several arguments are grouped into additional levels of
list structure in Lisp.

   Here is the @defspec line of an example of an imaginary special
form:

```
    - Special Form: foobar (var  [from  to  [inc ]]) body ...
```

In this example, the arguments from and to are optional, but must both
be present or both absent. If they are present, inc may optionally be
specified as well. These arguments are grouped with the argument var
into a list, to distinguish them from body, which includes all
remaining elements of the form.

   In a Texinfo source file, this @defspec line is written like this
(except it would not be split over two lines, as it is in this example).

    @defspec foobar (@var{var} [@var{from} @var{to}
         [@var{inc}]]) @var{body}@dots{}

The function is listed in the Command and Variable Index under foobar.

1.173 texi.info/deffnx

                    Two or More 'First' Lines
==========================

   To create two or more 'first' or header lines for a definition,
follow the first @deffn line by a line beginning with @deffnx. The
generate extra vertical white space between it and the preceding line.

   For example,

    @deffn {Interactive Command} isearch-forward
    @deffnx {Interactive Command} isearch-backward
    These two search commands are similar except ...
    @end deffn

produces

 – Interactive Command: isearch-forward
 – Interactive Command: isearch-backward
     These two search commands are similar except ...

   Each of the other definition commands has an 'x' form: @defunx,
   The 'x' forms work just like @itemx; see
               @itemx
                 .

1.174 texi.info/Def Cmds in Detail

                    The Definition Commands
=======================

   Texinfo provides more than a dozen definition commands, all of which
are described in this section.

   The definition commands automatically enter the name of the entity in
the appropriate index: for example, @deffn, @defun, and @defmac
enter function names in the index of functions; @defvr and @defvar
enter variable names in the index of variables.

   Although the examples that follow mostly illustrate Lisp, the

commands can be used for other programming languages.

1.175 texi.info/Functions Commands

Functions and Similar Entities

   This section describes the commands for describing functions and
similar entities:

 @deffn category name arguments ...
     The @deffn command is the general definition command for
     functions, interactive commands, and similar entities that may take
     arguments. You must choose a term to describe the category of
     entity being defined; for example, "Function" could be used if the
     entity is a function. The @deffn command is written at the
     beginning of a line and is followed on the same line by the
     category of entity being described, the name of this particular
     entity, and its arguments, if any. Terminate the definition with
     @end deffn on a line of its own.

     For example, here is a definition:

         @deffn Command forward-char nchars
         Move point forward @var{nchars} characters.
         @end deffn

     This shows a rather terse definition for a "command" named
     forward-char with one argument, nchars.

      @deffn prints argument names such as nchars in italics or upper
     case, as if @var had been used, because we think of these names
     as metasyntactic variables--they stand for the actual argument

     values. Within the text of the description, write an argument name
     explicitly with @var to refer to the value of the argument. In
     the example above, we used @var{nchars} in this way.

     The template for @deffn is:

          @deffn category name arguments ...
          body-of-definition
          @end deffn

 @defun name arguments ...
     The @defun command is the definition command for functions.
     @defun is equivalent to @deffn Function ....

     For example,

          @defun set symbol new-value
          Change the value of the symbol @var{symbol}
          to @var{new-value}.
          @end defun

     shows a rather terse definition for a function set whose arguments
     are symbol and new-value. The argument names on the @defun line
     automatically appear in italics or upper case as if they were
     enclosed in @var. Terminate the definition with @end defun on a
     line of its own.

     The template is:

          @defun function-name arguments ...
          body-of-definition
          @end defun

      @defun creates an entry in the index of functions.

 @defmac name arguments ...
     The @defmac command is the definition command for macros.
     @defmac is equivalent to @deffn Macro ... and works like @defun.

 @defspec name arguments ...
     The @defspec command is the definition command for special forms.
     (In Lisp, a special form is an entity much like a function.)
     @defspec is equivalent to @deffn {Special Form} ... and works
     like @defun.

1.176 texi.info/Variables Commands

Variables and Similar Entities

   Here are the commands for defining variables and similar entities:

 @defvr category name
     The @defvr command is a general definition command for something

like a variable--an entity that records a value. You must choose
a term to describe the category of entity being defined; for
example, "Variable" could be used if the entity is a variable.
Write the @defvr command at the beginning of a line and followed
it on the same line by the category of the entity and the name of
the entity.

Capitalize the category name like a title. If the name of the
category contains spaces, as in the name 'User Option', write
braces around it. Otherwise, the second word will be mistaken for
the name of the entity, for example:

```
@defvr {User Option} fill-column
This buffer-local variable specifies
the maximum width of filled lines.
...
@end defvr
```

Terminate the definition with @end defvr on a line of its own.

The template is:

```
@defvr category name
body-of-definition
@end defvr
```

 @defvr creates an entry in the index of variables for name.

@defvar name
    The @defvar command is the definition command for variables.
    @defvar is equivalent to @defvr Variable ....

    For example:

```
@defvar kill-ring
...
@end defvar
```

    The template is:

```
@defvar name
body-of-definition
@end defvar
```

     @defvar creates an entry in the index of variables for name.

@defopt name
    The @defopt command is the definition command for user options.
    @defopt is equivalent to @defvr {User Option} ... and works like
    @defvar.

1.177   texi.info/Typed Functions

Functions in Typed Languages

   The @deftypefn command and its variations are for describing
functions in C or any other language in which you must declare types of
variables and functions.

 @deftypefn category data-type name arguments ...
     The @deftypefn command is the general definition command for
     functions and similar entities that may take arguments and that are
     typed. The @deftypefn command is written at the beginning of a
     line and is followed on the same line by the category of entity
     being described, the type of the returned value, the name of this
     particular entity, and its arguments, if any.

     For example,

          @deftypefn {Library Function} int foobar
             (int @var{foo}, float @var{bar})
          ...
          @end deftypefn

     (where the text before the "...", shown above as two lines, would
     actually be a single line in a real Texinfo file) produces the
     following in Info:

          -- Library Function: int foobar (int FOO, float BAR)
          ...

     This means that foobar is a "library function" that returns an
     int, and its arguments are foo (an int) and bar (a float).

     The argument names that you write in @deftypefn are not subject
     to an implicit @var--since the actual names of the arguments in
     @deftypefn are typically scattered among data type names and
     keywords, Texinfo cannot find them without help. Instead, you
     must write @var explicitly around the argument names. In the
     example above, the argument names are foo and bar.

     The template for @deftypefn is:

          @deftypefn category data-type name arguments ...
          body-of-description
          @end deftypefn

     Note that if the category or data type is more than one word then
     it must be enclosed in braces to make it a single argument.

     If you are describing a procedure in a language that has packages,
     such as Ada, you might consider using @deftypefn in a manner
     somewhat contrary to the convention described in the preceding
     paragraphs.

     For example:

          @deftypefn stacks private push
                  (@var{s}:in out stack;

```
             @var{n}:in integer)
      ...
      @end deftypefn
```

(The @deftypefn arguments are shown split into three lines, but would be a single line in a real Texinfo file.)

In this instance, the procedure is classified as belonging to the package stacks rather than classified as a 'procedure' and its data type is described as private. (The name of the procedure is push, and its arguments are s and n.)

@deftypefn creates an entry in the index of functions for name.

@deftypefun data-type name arguments ...
    The @deftypefun command is the specialized definition command for functions in typed languages. The command is equivalent to @deftypefn Function ....

Thus,

```
      @deftypefun int foobar (int @var{foo}, float @var{bar})
      ...
      @end deftypefun
```

produces the following in Info:

```
      -- Function: int foobar (int FOO, float BAR)
      ...
```

The template is:

```
      @deftypefun type name arguments ...
      body-of-description
      @end deftypefun
```

@deftypefun creates an entry in the index of functions for name.

1.178   texi.info/Typed Variables

                Variables in Typed Languages

   Variables in typed languages are handled in a manner similar to functions in typed languages. See
                Typed Functions
                . The general
definition command @deftypevr corresponds to @deftypefn and the specialized definition command @deftypevar corresponds to @deftypefun.

@deftypevr category data-type name
    The @deftypevr command is the general definition command for something like a variable in a typed language--an entity that records a value. You must choose a term to describe the category

of the entity being defined; for example, "Variable" could be used
if the entity is a variable.

The @deftypevr command is written at the beginning of a line and
is followed on the same line by the category of the entity being
described, the data type, and the name of this particular entity.

For example:

```
@deftypevr {Global Flag} int enable
...
@end deftypevr
```

produces the following in Info:

```
-- Global Flag: int enable
...
```

The template is:

```
@deftypevr category data-type name
body-of-description
@end deftypevr
```

 @deftypevr creates an entry in the index of variables for name.

@deftypevar data-type name
    The @deftypevar command is the specialized definition command for
    variables in typed languages.   @deftypevar is equivalent to
    @deftypevr Variable ....

    For example:

```
@deftypevar int fubar
...
@end deftypevar
```

    produces the following in Info:

```
-- Variable: int fubar
...
```

    The template is:

```
@deftypevar data-type name
body-of-description
@end deftypevar
```

 @deftypevar creates an entry in the index of variables for name.

1.179   texi.info/Abstract Objects

Object-Oriented Programming

   Here are the commands for formatting descriptions about abstract
objects, such as are used in object-oriented programming. A class is a
defined type of abstract object. An instance of a class is a
particular object that has the type of the class. An instance variable
is a variable that belongs to the class but for which each instance has
its own value.

   In a definition, if the name of a class is truly a name defined in
the programming system for a class, then you should write an @code
around it. Otherwise, it is printed in the usual text font.

 @defcv category class name
     The @defcv command is the general definition command for
     variables associated with classes in object-oriented programming.
     The @defcv command is followed by three arguments: the category of
     thing being defined, the class to which it belongs, and its name.
     Thus,

          @defcv {Class Option} Window border-pattern
          ...
          @end defcv

     illustrates how you would write the first line of a definition of
     the border-pattern class option of the class Window.

     The template is

          @defcv category class name
          ...
          @end defcv

      @defcv creates an entry in the index of variables.

 @defivar class name
     The @defivar command is the definition command for instance
     variables in object-oriented programming.   @defivar is equivalent
     to @defcv {Instance Variable} ...

     The template is:

          @defivar class instance-variable-name
          body-of-definition
          @end defivar

      @defivar creates an entry in the index of variables.

 @defop category class name arguments ...
     The @defop command is the general definition command for entities
     that may resemble methods in object-oriented programming. These
     entities take arguments, as functions do, but are associated with
     particular classes of objects.

     For example, some systems have constructs called wrappers that are
     associated with classes as methods are, but that act more like

macros than like functions. You could use @defop Wrapper to
describe one of these.

Sometimes it is useful to distinguish methods and operations. You
can think of an operation as the specification for a method.
Thus, a window system might specify that all window classes have a
method named expose; we would say that this window system defines
an expose operation on windows in general. Typically, the
operation has a name and also specifies the pattern of arguments;
all methods that implement the operation must accept the same
arguments, since applications that use the operation do so without
knowing which method will implement it.

Often it makes more sense to document operations than methods. For
example, window application developers need to know about the
expose operation, but need not be concerned with whether a given
class of windows has its own method to implement this operation.
To describe this operation, you would write:

        @defop Operation windows expose

The @defop command is written at the beginning of a line and is
followed on the same line by the overall name of the category of
operation, the name of the class of the operation, the name of the
operation, and its arguments, if any.

The template is:

        @defop category class name arguments ...
        body-of-definition
        @end defop

 @defop creates an entry, such as 'expose on windows', in the
index of functions.

@defmethod class name arguments ...
    The @defmethod command is the definition command for methods in
    object-oriented programming. A method is a kind of function that
    implements an operation for a particular class of objects and its
    subclasses. In the Lisp Machine, methods actually were functions,
    but they were usually defined with defmethod.

     @defmethod is equivalent to @defop Method .... The command is
    written at the beginning of a line and is followed by the name of
    the class of the method, the name of the method, and its
    arguments, if any.

    For example,

        @defmethod bar-class bar-method argument
        ...
        @end defmethod

    illustrates the definition for a method called bar-method of the
    class bar-class. The method takes an argument.

    The template is:

```
        @defmethod class method-name arguments ...
        body-of-definition
        @end defmethod
```

   @defmethod creates an entry in the index of functions, such as
'bar-method on bar-class'.

1.180   texi.info/Data Types

```
Data Types
----------
```

   Here is the command for data types:

```
@deftp category name attributes ...
```
     The @deftp command is the generic definition command for data
     types. The command is written at the beginning of a line and is
     followed on the same line by the category, by the name of the type
     (which is a word like int or float), and then by names of
     attributes of objects of that type. Thus, you could use this
     command for describing int or float, in which case you could use
     data type as the category. (A data type is a category of certain
     objects for purposes of deciding which operations can be performed
     on them.)

     In Lisp, for example, pair names a particular data type, and an
     object of that type has two slots called the CAR and the CDR.
     Here is how you would write the first line of a definition of pair.

```
        @deftp {Data type} pair car cdr
        ...
        @end deftp
```

     The template is:

```
        @deftp category name-of-type attributes ...
        body-of-definition
        @end deftp
```

   @deftp creates an entry in the index of data types.

1.181   texi.info/Def Cmd Conventions

```
Conventions for Writing Definitions
===================================
```

   When you write a definition using @deffn, @defun, or one of the
other definition commands, please take care to use arguments that
indicate the meaning, as with the count argument to the forward-word

function. Also, if the name of an argument contains the name of a
type, such as integer, take care that the argument actually is of that
type.

1.182   texi.info/Sample Function Definition

A Sample Function Definition
============================

   A function definition uses the @defun and @end defun commands.
The name of the function follows immediately after the @defun command
and it is followed, on the same line, by the parameter list.

   Here is a definition from 'The GNU Emacs Lisp Reference Manual'.
(See Calling Functions.)

     – Function: apply function &rest arguments
         apply calls function with arguments, just like funcall but
         with one difference: the last of arguments is a list of
         arguments to give to function, rather than a single argument.
         We also say that this list is appended to the other
         arguments.

         apply returns the result of calling function. As with
         funcall, function must either be a Lisp function or a
         primitive function; special forms and macros do not make
         sense in apply.

```
             (setq f 'list)
                 => list
             (apply f 'x 'y 'z)
             error--> Wrong type argument: listp, z
             (apply '+ 1 2 '(3 4))
                 => 10
             (apply '+ '(1 2 3 4))
                 => 10

             (apply 'append '((a b c) nil (x y z) nil))
                 => (a b c x y z)
```

         An interesting example of using apply is found in the
         description of mapcar.

   In the Texinfo source file, this example looks like this:

```
     @defun apply function &rest arguments

     @code{apply} calls @var{function} with
     @var{arguments}, just like @code{funcall} but with one
     difference: the last of @var{arguments} is a list of
     arguments to give to @var{function}, rather than a single
     argument.  We also say that this list is @dfn{appended}
     to the other arguments.
```

```
    @code{apply} returns the result of calling
    @var{function}.  As with @code{funcall},
    @var{function} must either be a Lisp function or a
    primitive function; special forms and macros do not make
    sense in @code{apply}.

    @example
    (setq f 'list)
         @result{} list
    (apply f 'x 'y 'z)
    @error{} Wrong type argument: listp, z
    (apply '+ 1 2 '(3 4))
         @result{} 10
    (apply '+ '(1 2 3 4))
         @result{} 10

    (apply 'append '((a b c) nil (x y z) nil))
         @result{} (a b c x y z)
    @end example

    An interesting example of using @code{apply} is found
    in the description of @code{mapcar}.@refill
    @end defun
```

In this manual, this function is listed in the Command and Variable
Index under apply.

   Ordinary variables and user options are described using a format like
that for functions except that variables do not take arguments.

1.183 texi.info/Footnotes

```
Footnotes
*********
```

   A footnote is for a reference that documents or elucidates the
primary text.(1)

   In Texinfo, footnotes are created with the @footnote command. This
command is followed immediately by a left brace, then by the text of
the footnote, and then by a terminating right brace. The template is:

    @footnote{text }

   Footnotes may be of any length, but are usually short.

   For example, this clause is followed by a sample footnote(2); in the
Texinfo source, it looks like this:

    ...a sample footnote @footnote{Here is the sample
    footnote.}; in the Texinfo source...

   In a printed manual or book, the reference mark for a footnote is a
small, superscripted number; the text of the footnote is written at the

bottom of the page, below a horizontal line.

   In Info, the reference mark for a footnote is a pair of parentheses
with the footnote number between them, like this: (1).

   Info has two footnote styles, which determine where the text of the
footnote is located:

   * In the 'End' node style, all the footnotes for a single node are
     placed at the end of that node. The footnotes are separated from
     the rest of the node by a line of dashes with the word Footnotes
     within it. Each footnote begins with an (n) reference mark.

     Here is an example of a single footnote in the end of node style:

         --------- Footnotes ---------

         (1) Here is a sample footnote.

   * In the 'Separate' node style, all the footnotes for a single node
     are placed in an automatically constructed node of their own. In
     this style, a "footnote reference" follows each (n) reference
     mark in the body of the node. The footnote reference is actually
     a cross reference which you use to reach the footnote node.

     The name of the node containing the footnotes is constructed by
     appending -Footnotes to the name of the node that contains the
     footnotes. (Consequently, the footnotes' node for the Footnotes
     node is Footnotes-Footnotes!) The footnotes' node has an 'Up'
     node pointer that leads back to its parent node.

     Here is how the first footnote in this manual looks after being
     formatted for Info in the separate node style:

         File: texinfo.info Node: Overview-Footnotes, Up: Overview

         (1) Note that the first syllable of "Texinfo" is
         pronounced like "speck", not "hex". ...

   A Texinfo file may be formatted into an Info file with either
footnote style.

   Use the @footnotestyle command to specify an Info file's footnote
style. Write this command at the beginning of a line followed by an
argument, either end for the end node style or separate for the
separate node style.

   For example,

     @footnotestyle end

or
     @footnotestyle separate

   Write an @footnotestyle command before or shortly after the
end-of-header line at the beginning of a Texinfo file. (If you include
the @footnotestyle command between the start-of-header and

end-of-header lines, the region formatting commands will format
footnotes as specified.)

   If you do not specify a footnote style, the formatting commands use
their default style. Currently, makeinfo uses the 'end' style, while
texinfo-format-buffer and texinfo-format-region use the 'separate'
style.

   This chapter contains two footnotes.

   ---------- Footnotes ----------

   (1) A footnote should complement or expand upon the primary text,
but a reader should not need to read a footnote to understand the
primary text. For a thorough discussion of footnotes, see 'The Chicago
Manual of Style', which is published by the University of Chicago Press.

   (2) Here is the sample footnote.

1.184   texi.info/Conditionals

                    Conditionally Visible Text
****

   Sometimes it is good to use different text for a printed manual and
its corresponding Info file. In this case, you can use the conditional
commands to specify which text is for the printed manual and which is
for the Info file.

                    Conditional Commands
                          How to specify text for Info or TeX.

                    Using Ordinary TeX Commands
                      You can use any and all TeX commands.

                    set clear value
                              How to designate which text to format (for
                                  both Info and TeX); and how to set a
                                  flag to a string that you can insert.

1.185   texi.info/Conditional Commands

                    Using @ifinfo and @iftex
==========================

   @ifinfo begins segments of text that should be ignored by TeX when
it typesets the printed manual. The segment of text appears only in

the Info file. The @ifinfo command should appear on a line by itself;
end the Info-only text with a line containing @end ifinfo by itself.
At the beginning of a Texinfo file, the Info permissions are contained
within a region marked by @ifinfo and @end ifinfo. (See

                  Info Summary and Permissions
                  .)

   The @iftex and @end iftex commands are similar to the @ifinfo and
 @end ifinfo commands, except that they specify text that will appear
in the printed manual but not in the Info file.

   For example,

      @iftex
      This text will appear only in the printed manual.
      @end iftex

      @ifinfo
      However, this text will appear only in Info.
      @end ifinfo

The preceding example produces the following line:

   However, this text will appear only in Info.

Note how you only see one of the two lines, depending on whether you
are reading the Info version or the printed version of this manual.

   The @titlepage command is a special variant of @iftex that is used
for making the title and copyright pages of the printed manual. (See

                  @titlepage
                  .)

1.186   texi.info/Using Ordinary TeX Commands

Using Ordinary TeX Commands
===========================

   Inside a region delineated by @iftex and @end iftex, you can embed
some PlainTeX commands. Info will ignore these commands since they are
only in that part of the file which is seen by TeX. You can write the
TeX commands as you would write them in a normal TeX file, except that
you must replace the \ used by TeX with an @. For example, in the
Info to ignore the region automatically, as it does with the @iftex
command.)

   However, many features of PlainTeX will not work, as they are
overridden by features of Texinfo.

   You can enter PlainTeX completely, and use \ in the TeX commands,
by delineating a region with the @tex and @end tex commands. (The

command.)

   For example, here is a mathematical expression written in PlainTeX:

```
   @tex
   $$ \chi^2 = \sum_{i=1}^N
             \left (y_i - (a + b x_i)
             \over \sigma_i\right)^2 $$
   @end tex
```

The output of this example will appear only in a printed manual. If
you are reading this in Info, you will not see anything after this
paragraph.

1.187   texi.info/set clear value

                      @set, @clear, and @value
=============================

   You can direct the Texinfo formatting commands to format or ignore
parts of a Texinfo file with the @set, @clear, @ifset, and @ifclear
commands.

   In addition, you can use the @set flag command to set the value of
flag to a string of characters; and use @value{flag } to insert that
string. You can use @set, for example, to set a date and use @value
to insert the date in several places in the Texinfo file.

                      ifset ifclear
                                Format a region if a flag is set.

                      value
                                        Replace a flag with a string.

                      value Example
                                An easy way to update edition information.

1.188   texi.info/ifset ifclear

 @ifset and @ifclear

   When a flag is set, the Texinfo formatting commands format text
between subsequent pairs of @ifset flag and @end ifset commands.
When the flag is cleared, the Texinfo formatting commands do not format
the text.

Use the @set flag command to turn on, or set, a flag; a flag can be
any single word. The format for the command looks like this:

    @set flag

  Write the conditionally formatted text between @ifset flag and
    @ifset flag
    conditional-text
    @end ifset

  For example, you can create one document that has two variants, such
as a manual for a 'large' and 'small' model:

    You can use this machine to dig up shrubs
    without hurting them.

    @set large

    @ifset large
    It can also dig up fully grown trees.
    @end ifset

    Remember to replant promptly ...

In the example, the formatting commands will format the text between
  Use the @clear flag command to turn off, or clear, a flag.
Clearing a flag is the opposite of setting a flag. The command looks
like this:

    @clear flag

Write the command on a line of its own.

  When flag is cleared, the Texinfo formatting commands do not format
the text between @ifset flag and @end ifset; that text is ignored and
does not appear in either printed or Info output.

  For example, if you clear the flag of the preceding example by
writing an @clear large command after the @set large command (but
before the conditional text), then the Texinfo formatting commands
ignore the text between the @ifset large and @end ifset commands. In
the formatted output, that text does not appear; in both printed and
Info output, you see only the lines that say, "You can use this machine
to dig up shrubs without hurting them. Remember to replant promptly
...".

  If a flag is cleared with an @clear flag command, then the
formatting commands format text between subsequent pairs of @ifclear
and @end ifclear commands. But if the flag is set with @set flag,
then the formatting commands do not format text between an @ifclear
and an @end ifclear command; rather, they ignore that text. An
    @ifclear flag

  In brief, the commands are:

 @set flag
    Tell the Texinfo formatting commands that flag is set.

```
@clear flag
     Tell the Texinfo formatting commands that flag is cleared.

@ifset flag
     If flag is set, tell the Texinfo formatting commands to format the
     text up to the following  @end ifset command.

     If flag is cleared, tell the Texinfo formatting commands to ignore
     text up to the following  @end ifset command.

@ifclear flag
     If flag is set, tell the Texinfo formatting commands to ignore the
     text up to the following  @end ifclear command.

     If flag is cleared, tell the Texinfo formatting commands to format
     the text up to the following  @end ifclear command.
```

1.189 texi.info/value

```
 @value
 -------
```

   You can use the @set command to specify a value for a flag, which
is expanded by the @value command. The value is a string a characters.

   Write the @set command like this:

```
     @set foo This is a string.
```

This sets the value of foo to "This is a string."

   The Texinfo formatters replace an @value{flag } command with the
string to which flag is set.

   Thus, when foo is set as shown above, the Texinfo formatters convert

```
     @value{foo}
```
to
```
     This is a string.
```

   You can write an @value command within a paragraph; but you must
write an @set command on a line of its own.

   If you write the @set command like this:

```
     @set foo
```

without specifying a string, the value of foo is an empty string.

   If you clear a previously set flag with an @clear flag command, a
subsequent @value{flag} command is invalid and the string is replaced
with an error message that says {No value for "flag"}.

For example, if you set foo as follows:

```
@set how-much very, very, very
```

then the formatters transform

```
It is a @value{how-much} wet day.
```
into
```
It is a very, very, very wet day.
```

If you write

```
@clear how-much
```

then the formatters transform

```
It is a @value{how-much} wet day.
```
into
```
It is a {No value for "how-much"} wet day.
```

1.190   texi.info/value Example

```
 @value Example
 --------------
```

You can use the @value command to limit the number of places you need to change when you record an update to a manual. Here is how it is done in 'The GNU Make Manual':

Set the flags:

```
@set EDITION 0.35 Beta
@set VERSION 3.63 Beta
@set UPDATED 14 August 1992
@set UPDATE-MONTH August 1992
```

Write text for the first @ifinfo section, for people reading the Texinfo file:

```
This is Edition @value{EDITION},
last updated @value{UPDATED},
of @cite{The GNU Make Manual},
for @code{make}, Version @value{VERSION}.
```

Write text for the title page, for people reading the printed manual:

```
@title GNU Make
@subtitle A Program for Directing Recompilation
@subtitle Edition @value{EDITION}, ...
@subtitle @value{UPDATE-MONTH}
```

(On a printed cover, a date listing the month and the year looks less fussy than a date listing the day as well as the month and year.)

Write text for the Top node, for people reading the Info file:

```
This is Edition @value{EDITION}
of the @cite{GNU Make Manual},
last updated @value{UPDATED}
for @code{make} Version @value{VERSION}.
```

   After you format the manual, the text in the first @ifinfo section
looks like this:

```
This is Edition 0.35 Beta, last updated 14 August 1992,
of 'The GNU Make Manual', for 'make', Version 3.63 Beta.
```

   When you update the manual, change only the values of the flags; you
do not need to rewrite the three sections.

1.191   texi.info/Format-Print Hardcopy

```
                   Format and Print Hardcopy
**************************
```

   There are three major shell commands for making a printed manual
from a Texinfo file: one for converting the Texinfo file into a file
that will be printed, a second for sorting indices, and a third for
printing the formatted document. When you use the shell commands, you
can either work directly in the operating system shell or work within a
shell inside GNU Emacs.

   If you are using GNU Emacs, you can use commands provided by Texinfo
mode instead of shell commands. In addition to the three commands to
format a file, sort the indices, and print the result, Texinfo mode
offers key bindings for commands to recenter the output buffer, show the
print queue, and delete a job from the print queue.

```
            Use TeX
                              Use TeX to format for hardcopy.

            Shell Format & Print
                   How to format and print a hardcopy manual
                        with shell commands.

            Within Emacs

```

1.192   texi.info/Use TeX

Use TeX
=======

   The typesetting program called TeX is used for formatting a Texinfo
file. TeX is a very powerful typesetting program and, if used right,
does an exceptionally good job. See
                How to Obtain TeX
                , for information
on how to obtain TeX.

   The makeinfo, texinfo-format-region, and texinfo-format-buffer
commands read the very same @-commands in the Texinfo file as does TeX,
but process them differently to make an Info file; see

                Create an Info File
                .

1.193   texi.info/Shell Format & Print

Format and Print Using Shell Commands
=====================================

   Format the Texinfo file with the shell command tex followed by the
name of the Texinfo file. This produces a formatted DVI file as well
as several auxiliary files containing indices, cross references, etc.
The DVI file (for DeVice Independent file) can be printed on a wide
variety of printers.

   The tex formatting command itself does not sort the indices; it

writes an output file of unsorted index data. This is a misfeature of
TeX. Hence, to generate a printed index, you first need a sorted index
to work from. The texindex command sorts indices. (The source file
texindex.c comes as part of the standard GNU distribution and is
usually installed when Emacs is installed.)

   The tex formatting command outputs unsorted index files under names
that obey a standard convention. These names are the name of your main
input file to the tex formatting command, with everything after the
first period thrown away, and the two letter names of indices added at
the end. For example, the raw index output files for the input file
foo.texinfo would be foo.cp, foo.vr, foo.fn, foo.tp, foo.pg and foo.ky.
Those are exactly the arguments to give to texindex.

   Or else, you can use ?? as "wild-cards" and give the command in this
form:

      texindex foo.??

This command will run texindex on all the unsorted index files,
including any that you have defined yourself using @defindex or
similarly named files with two letter extensions that are not index
files, such as foo.el. The texindex command reports but otherwise
ignores such files.)

   For each file specified, texindex generates a sorted index file
whose name is made by appending s to the input file name. The
does not alter the raw index output file.

   After you have sorted the indices, you need to rerun the tex
formatting command on the Texinfo file. This regenerates a formatted
DVI file with up-to-date index entries.(1)

   To summarize, this is a three step process:

  1. Run the tex formatting command on the Texinfo file. This
     generates the formatted DVI file as well as the raw index files
     with two letter extensions.

  2. Run the shell command texindex on the raw index files to sort
     them. This creates the corresponding sorted index files.

  3. Rerun the tex formatting command on the Texinfo file. This
     regenerates a formatted DVI file with the index entries in the
     correct order. This second run also corrects the page numbers for
     the cross references. (The tables of contents are always correct.)

   You need not run texindex each time after you run the tex
formatting. If you do not, on the next run, the tex formatting command
will use whatever sorted index files happen to exist from the previous
use of texindex. This is usually OK while you are debugging.

   Rather than type the tex and texindex commands yourself, you can use
texi2dvi. This shell script is designed to simplify the
tex--texindex--tex sequence by figuring out whether
index files and DVI files are up-to-date. It runs texindex and tex
only when necessary.

   The syntax for texi2dvi is like this (where % is the shell prompt):

     % texi2dvi filename ...

   Finally, you can print the DVI file with the DVI print command. The
precise command to use depends on the system; lpr -d is common. The
DVI print command may require a file name without any extension or with
a .dvi extension.

   The following commands, for example, sort the indices, format, and
print the 'Bison Manual' (where % is the shell prompt):

     % tex bison.texinfo
     % texindex bison.??
     % tex bison.texinfo
     % lpr -d bison.dvi

(Remember that the shell commands may be different at your site; but
these are commonly used versions.)

     ---------- Footnotes ----------

   (1) If you use more than one index and have cross references to an
index other than the first, you must run tex three times to get correct
output: once to generate raw index data; again (after texindex) to
output the text of the indices and determine their true page numbers;
and a third time to output correct page numbers in cross references to
them. However, cross references to indices are rare.

1.194   texi.info/Within Emacs

                   From an Emacs Shell ...
========================

   You can give formatting and printing commands from a shell within GNU
Emacs. To create a shell within Emacs, type M-x shell. In this shell,
you can format and print the document. See

                   How to Format and Print Using Shell Commands
                  , for details.

   You can switch to and from the shell buffer while tex is running and
do other editing. If you are formatting a long document on a slow
machine, this can be very convenient.

   You can also use texi2dvi from an Emacs shell. For example, here is
how to use texi2dvi to format and print 'Using and Porting GNU CC' from
a shell within Emacs (where % is the shell prompt):

     % texi2dvi gcc.texinfo
     % lpr -d gcc.dvi

   See

                         Texinfo Mode Printing
                     , for more information about formatting and
printing in Texinfo mode.

1.195   texi.info/Texinfo Mode Printing

Formatting and Printing in Texinfo Mode
=======================================

   Texinfo mode provides several predefined key commands for TeX
formatting and printing. These include commands for sorting indices,
looking at the printer queue, killing the formatting job, and
recentering the display of the buffer in which the operations occur.

C-c C-t C-r
M-x texinfo-tex-region
     Run TeX on the current region.

C-c C-t C-b
M-x texinfo-tex-buffer
     Run TeX on the current buffer.

C-c C-t C-i
M-x texinfo-texindex
     Sort the indices of a Texinfo file that have been formatted with
     texinfo-tex-region or texinfo-tex-buffer.

C-c C-t C-p
M-x texinfo-tex-print
     Print a DVI file that was made with texinfo-tex-region or
     texinfo-tex-buffer.

C-c C-t C-q
M-x texinfo-show-tex-print-queue
     Show the print queue.

C-c C-t C-d
M-x texinfo-delete-from-tex-print-queue
     Delete a job from the print queue; you will be prompted for the job
     number shown by a preceding C-c C-t C-q command
     (texinfo-show-tex-print-queue).

C-c C-t C-k
M-x texinfo-kill-tex-job
     Kill either the currently running TeX job that has been started by
     texinfo-tex-region or texinfo-tex-buffer, or any other process
     running in the Texinfo shell buffer.

C-c C-t C-x
M-x texinfo-quit-tex-job
     Quit a TeX formatting job that has stopped because of an error by
     sending an x to it. When you do this, TeX preserves a record of
     what it did in a .log file.

```
C-c C-t C-l
M-x texinfo-recenter-tex-output-buffer
     Redisplay the shell buffer in which the TeX printing and formatting
     commands are run to show its most recent output.
```

   Thus, the usual sequence of commands for formatting a buffer is as
follows (with comments to the right):

```
   C-c C-t C-b               Run TeX on the buffer.
   C-c C-t C-i               Sort the indices.
   C-c C-t C-b               Rerun TeX to regenerate indices.
   C-c C-t C-p               Print the DVI file.
   C-c C-t C-q               Display the printer queue.
```

   The Texinfo mode TeX formatting commands start a subshell in Emacs
called the *texinfo-tex-shell*. The texinfo-tex-command,
texinfo-texindex-command, and tex-dvi-print-command commands are all
run in this shell.

   You can watch the commands operate in the *texinfo-tex-shell* buffer,
and you can switch to and from and use the *texinfo-tex-shell* buffer
as you would any other shell buffer.

   The formatting and print commands depend on the values of several
variables. The default values are:

```
        Variable                             Default value

   texinfo-tex-command                        "tex"
   texinfo-texindex-command                   "texindex"
   texinfo-tex-shell-cd-command               "cd"
   texinfo-tex-dvi-print-command              "lpr -d"
   texinfo-show-tex-queue-command             "lpq"
   texinfo-delete-from-print-queue-command    "lprm"
   texinfo-start-of-header                    "%**start"
   texinfo-end-of-header                      "%**end"
   texinfo-tex-trailer                        "@bye"
```

   The default values of both the texinfo-tex-command and the
texinfo-texindex-command variables are set in the texnfo-tex.el file.

   You can change the values of these variables with the M-x
edit-options command (see Editing Variable Values), with the M-x
set-variable command (see Examining and Setting Variables), or with
your .emacs initialization file (see Init File).

1.196 texi.info/Compile-Command

```
Using the Local Variables List
==============================
```

   Yet another way to apply the TeX formatting command to a Texinfo
file is to put that command in a local variables list at the end of the

Texinfo file. You can then specify the TeX formatting command as a compile-command and have Emacs run the TeX formatting command by typing M-x compile. This creates a special shell called the *compilation buffer* in which Emacs runs the compile command. For example, at the end of the gdb.texinfo file, after the @bye, you would put the following:

```
@c Local Variables:
@c compile-command: "tex gdb.texinfo"
@c End:
```

This technique is most often used by programmers who also compile programs this way; see Compilation.

1.197 texi.info/Requirements Summary

```
            TeX Formatting Requirements Summary
====================================
```

Every Texinfo file that is to be input to TeX must begin with a \input command and contain an @settitle command:

```
    \input texinfo
    @settitle name-of-manual
```

The first command instructs TeX to load the macros it needs to process a Texinfo file and the second command specifies the title of printed manual.

Every Texinfo file must end with a line that terminates TeX processing and forces out unfinished pages:

```
    @bye
```

Strictly speaking, these three lines are all a Texinfo file needs for TeX, besides the body. (The @setfilename line is the only line that a Texinfo file needs for Info formatting.)

Usually, the file's first line contains an @c -*-texinfo-*- comment that causes Emacs to switch to Texinfo mode when you edit the file. In addition, the beginning usually includes an @setfilename for Info formatting, an @setchapternewpage command, a title page, a copyright page, and permissions. Besides an @bye, the end of a file usually includes indices and a table of contents.

For more information, see

    @setchapternewpage

    ,

    Page Headings

    ,

    Titlepage & Copyright Page

,

        Printing Indices & Menus
        , and

        Contents
        .

1.198 texi.info/Preparing for TeX

```
Preparing to Use TeX
====================
```

TeX needs to know where to find the texinfo.tex file that you have told
it to input with the \input texinfo command at the beginning of the
first line. The texinfo.tex file tells TeX how to handle @-commands.
(texinfo.tex is included in the standard GNU distributions.)

   Usually, the texinfo.tex file is put in the default directory that
contains TeX macros (the /usr/lib/tex/macros directory) when GNU Emacs
or other GNU software is installed. In this case, TeX will find the
file and you do not need to do anything special. Alternatively, you
can put texinfo.tex in the directory in which the Texinfo source file
is located, and TeX will find it there.

   However, you may want to specify the location of the \input file
yourself. One way to do this is to write the complete path for the file
after the \input command. Another way is to set the TEXINPUTS
environment variable in your .cshrc or .profile file. The TEXINPUTS
environment variable will tell TeX where to find the texinfo.tex file
and any other file that you might want TeX to use.

   Whether you use a .cshrc or .profile file depends on whether you use
csh, sh, or bash for your shell command interpreter. When you use csh,
it looks to the .cshrc file for initialization information, and when
you use sh or bash, it looks to the .profile file.

   In a .cshrc file, you could use the following csh command sequence:

      setenv TEXINPUTS .:/usr/me/mylib:/usr/lib/tex/macros

   In a .profile file, you could use the following sh command sequence:

      TEXINPUTS=.:/usr/me/mylib:/usr/lib/tex/macros
      export TEXINPUTS

This would cause TeX to look for \input file first in the current
directory, indicated by the ., then in a hypothetical user's me/mylib
directory, and finally in the system library.

1.199 texi.info/Overfull hboxes

```
                Overfull "hboxes"
==================
```

   TeX is sometimes unable to typeset a line without extending it into
the right margin. This can occur when TeX comes upon what it
interprets as a long word that it cannot hyphenate, such as an
electronic mail network address or a very long title. When this
happens, TeX prints an error message like this:

```
     Overfull \hbox (20.76302pt too wide)
```

(In TeX, lines are in "horizontal boxes", hence the term, "hbox". The
backslash, \ , is the TeX equivalent of @.)

   TeX also provides the line number in the Texinfo source file and the
text of the offending line, which is marked at all the places that TeX
knows how to hyphenate words. See

```
                Catching Errors with TeX Formatting
```
```
                ,
```
for more information about typesetting errors.

   If the Texinfo file has an overfull hbox, you can rewrite the
sentence so the overfull hbox does not occur, or you can decide to
leave it. A small excursion into the right margin often does not
matter and may not even be noticeable.

   However, unless told otherwise, TeX will print a large, ugly, black
rectangle beside the line that contains the overful hbox. This is so
you will notice the location of the problem if you are correcting a
draft.

   To prevent such a monstrosity from marring your final printout, write
the following in the beginning of the Texinfo file on a line of its own,
before the @titlepage command:

```
     @finalout
```

1.200 texi.info/smallbook

```
                Printing "Small" Books
======================
```

   By default, TeX typesets pages for printing in an 8.5 by 11 inch
format. However, you can direct TeX to typeset a document in a 7 by
9.25 inch format that is suitable for bound books by inserting the
following command on a line by itself at the beginning of the Texinfo
file, before the title page:

```
     @smallbook
```

(Since regular sized books are often about 7 by 9.25 inches, this
command might better have been called the @regularbooksize command,
but it came to be called the @smallbook command by comparison to the
8.5 by 11 inch format.)

   If you write the @smallbook command between the start-of-header and
end-of-header lines, the Texinfo mode TeX region formatting command,
texinfo-tex-region, will format the region in "small" book size (see

              Start of Header
).

   The Free Software Foundation distributes printed copies of 'The GNU
Emacs Manual' and other manuals in the "small" book size. See

              @smallexample and @smalllisp
              , for information about commands that make
it easier to produce examples for a smaller manual.

1.201 texi.info/A4 Paper

Printing on A4 Paper
====================

   You can tell TeX to typeset a document for printing on European size
A4 paper with the @afourpaper command. Write the command on a line by
itself between @iftex and @end iftex lines near the beginning of the
Texinfo file, before the title page:

   For example, this is how you would write the header for this manual:

     \input texinfo   @c -*-texinfo-*-
     @c %**start of header
     @setfilename texinfo
     @settitle Texinfo
     @syncodeindex vr fn
     @iftex
     @afourpaper
     @end iftex
     @c %**end of header

1.202 texi.info/Cropmarks and Magnification

Cropmarks and Magnification
===========================

   You can attempt to direct TeX to print cropmarks at the corners of
pages with the @cropmarks command. Write the @cropmarks command on a
line by itself between @iftex and @end iftex lines near the beginning

of the Texinfo file, before the title page, like this:

```
@iftex
@cropmarks
@end iftex
```

   This command is mainly for printers that typeset several pages on one
sheet of film; but you can attempt to use it to mark the corners of a
book set to 7 by 9.25 inches with the @smallbook command. (Printers
will not produce cropmarks for regular sized output that is printed on
regular sized paper.) Since different printing machines work in
different ways, you should explore the use of this command with a
spirit of adventure. You may have to redefine the command in the
texinfo.tex definitions file.

   You can attempt to direct TeX to typeset pages larger or smaller than
usual with the \mag TeX command. Everything that is typeset is scaled
proportionally larger or smaller. (\mag stands for "magnification".)
This is not a Texinfo @-command, but is a PlainTeX command that is
prefixed with a backslash. You have to write this command between
   Follow the \mag command with an = and then a number that is 1000
times the magnification you desire. For example, to print pages at 1.2
normal size, write the following near the beginning of the Texinfo
file, before the title page:

```
@tex
\mag=1200
@end tex
```

   With some printing technologies, you can print normal-sized copies
that look better than usual by using a larger-than-normal master.

   Depending on your system, \mag may not work or may work only at
certain magnifications. Be prepared to experiment.

1.203   texi.info/Create an Info File

```
                  Creating an Info File
*********************
```

   makeinfo is a utility that converts a Texinfo file into an Info
file; texinfo-format-region and texinfo-format-buffer are GNU Emacs
functions that do the same.

   A Texinfo file must possess an @setfilename line near its
beginning, otherwise the Info formatting commands will fail.

   For information on installing the Info file in the Info system, see

```
                  Install an Info File
                     .
```

1.204   texi.info/makeinfo advantages

makeinfo Preferred
==================

   The makeinfo utility creates an Info file from a Texinfo source file
more quickly than either of the Emacs formatting commands and provides
better error messages. We recommend it. makeinfo is a C program that
is independent of Emacs. You do not need to run Emacs to use makeinfo,
which means you can use makeinfo on machines that are too small to run
Emacs. You can run makeinfo in any one of three ways: from an operating
system shell, from a shell inside Emacs, or by typing a key command in
Texinfo mode in Emacs.

   The texinfo-format-region and the texinfo-format-buffer commands are
useful if you cannot run makeinfo. Also, in some circumstances, they
format short regions or buffers more quickly than makeinfo.

1.205   texi.info/Invoking makeinfo

            Invoking makeinfo from a Shell
==============================

   To create an Info file from a Texinfo file, type makeinfo followed
by the name of the Texinfo file. Thus, to create the Info file for
Bison, type the following at the shell prompt (where % is the prompt):

     % makeinfo bison.texinfo

   (You can run a shell inside Emacs by typing M-x shell.)

   Sometimes you will want to specify options. For example, if you wish
to discover which version of makeinfo you are using, type:

     % makeinfo --version

   See

               makeinfo options
               , for more information.

1.206   texi.info/makeinfo options

               Options for makeinfo
====================

   The makeinfo command takes a number of options. Most often, options
are used to set the value of the fill column and specify the footnote
style. Each command line option is a word preceded by - (1) or a
letter preceded by -. You can use abbreviations for the option names
as long as they are unique.

   For example, you could use the following command to create an Info
file for bison.texinfo in which each line is filled to only 68 columns
(where % is the prompt):

     % makeinfo --fill-column=68 bison.texinfo

   You can write two or more options in sequence, like this:

     % makeinfo --no-split --fill-column=70 ...

This would keep the Info file together as one possibly very long file
and would also set the fill column to 70.

   The options are:

-D var
     Cause var to be defined. This is equivalent to @set var in the
     Texinfo file.

-error-limit limit
     Set the maximum number of errors that makeinfo will report before
     exiting (on the assumption that continuing would be useless). The
     default number of errors that can be reported before makeinfo gives up
     is 100.

-fill-column width
     Specify the maximum number of columns in a line; this is the
     right-hand edge of a line. Paragraphs that are filled will be
     filled to this width. (Filling is the process of breaking up and
     connecting lines so that lines are the same length as or shorter
     than the number specified as the fill column. Lines are broken
     between words.) The default value for fill-column is 72.

-footnote-style style
     Set the footnote style to style, either end for the end node style
     or separate for the separate node style. The value set by this
     option overrides the value set in a Texinfo file by an
     @footnotestyle command. When the footnote style is separate,
     makeinfo makes a new node containing the footnotes found in the
     current node. When the footnote style is end, makeinfo places the
     footnote references at the end of the current node.

-I dir
     Add dir to the directory search list for finding files that are
     included using the @include command. By default, makeinfo
     searches only the current directory.

-no-headers
     Do not include menus or node lines in the output. This results in
     an ASCII file that you cannot read in Info since it does not
     contain the requisite nodes or menus; but you can print such a
     file in a single, typewriter-like font and produce acceptable
     output.

-no-split
     Suppress the splitting stage of makeinfo. Normally, large output
     files (where the size is greater than 70k bytes) are split into
     smaller subfiles, each one approximately 50k bytes. If you specify
     -no-split, makeinfo will not split up the output file.

-no-pointer-validate
-no-validate
     Suppress the pointer-validation phase of makeinfo. Normally,
     after a Texinfo file is processed, some consistency checks are
     made to ensure that cross references can be resolved, etc. See

               Pointer Validation
               .

-no-warn
     Suppress the output of warning messages. This does not suppress
     the output of error messages, only warnings. You might want this
     if the file you are creating has examples of Texinfo cross
     references within it, and the nodes that are referenced do not
     actually exist.

-no-number-footnotes
     Supress automatic footnote numbering. By default, makeinfo
     numbers each footnote sequentially in a single node, resetting the
     current footnote number to 1 at the start of each node.

```
-output file
-o file
     Specify that the output should be directed to file and not to the
     file name specified in the  @setfilename command found in the
     Texinfo source.  file can be the special token -, which specifies
     standard output.

-paragraph-indent indent
     Set the paragraph indentation style to indent.  The value set by
     this option overrides the value set in a Texinfo file by an
     @paragraphindent command.  The value of indent is interpreted as
     follows:

          * If the value of indent is asis, do not change the existing
            indentation at the starts of paragraphs.

          * If the value of indent is zero, delete any existing
            indentation.

          * If the value of indent is greater than zero, indent each
            paragraph by that number of spaces.

-reference-limit limit
     Set the value of the number of references to a node that makeinfo
     will make without reporting a warning.  If a node has more than
     this number of references in it, makeinfo will make the references
     but also report a warning.

-U var
     Cause var to be undefined.  This is equivalent to  @clear var in
     the Texinfo file.

-verbose
     Cause makeinfo to display messages saying what it is doing.
     Normally, makeinfo only outputs messages if there are errors or
     warnings.

-version
     Report the version number of this copy of makeinfo.

     ---------- Footnotes ----------

   (1)  - has replaced +, the old introductory character, to maintain
POSIX.2 compatibility without losing long-named options.
```

1.207 texi.info/Pointer Validation

```
Pointer Validation
==================

   makeinfo will check the validity of the final Info file unless you
suppress pointer-validation by using the -no-pointer-validation option.
Mostly, this means ensuring that nodes you have referenced really
```

exist. Here is a complete list of what is checked:

1. If a 'Next', 'Previous', or 'Up' node reference is a reference to a
   node in the current file and is not an external reference such as
   to (dir), then the referenced node must exist.

2. In every node, if the 'Previous' node is different from the 'Up'
   node, then the 'Previous' node must also be pointed to by a 'Next'
   node.

3. Every node except the 'Top' node must have an 'Up' pointer.

4. The node referenced by an 'Up' pointer must contain a reference to
   the current node in some manner other than through a 'Next'
   reference. This includes menu entries and cross references.

5. If the 'Next' reference of a node is not the same as the 'Next'
   reference of the 'Up' reference, then the node referenced by the
   'Next' pointer must have a 'Previous' pointer that points back to
   the current node. This rule allows the last node in a section to
   point to the first node of the next chapter.

1.208   texi.info/makeinfo in Emacs

                    Running makeinfo inside Emacs
==============================

   You can run makeinfo in GNU Emacs Texinfo mode by using either the
makeinfo-region or the makeinfo-buffer commands. In Texinfo mode, the
commands are bound to C-c C-m C-r and C-c C-m C-b by default.

C-c C-m C-r
M-x makeinfo-region
     Format the current region for Info.

C-c C-m C-b
M-x makeinfo-buffer
     Format the current buffer for Info.

   When you invoke either makeinfo-region or makeinfo-buffer, Emacs
prompts for a file name, offering the name of the visited file as the
default. You can edit the default file name in the minibuffer if you
wish, before typing RET to start the makeinfo process.

   The Emacs makeinfo-region and makeinfo-buffer commands run the
makeinfo program in a temporary shell buffer. If makeinfo finds any
errors, Emacs displays the error messages in the temporary buffer.

   You can parse the error messages by typing C-x ' (next-error). This
causes Emacs to go to and position the cursor on the line in the
Texinfo source that makeinfo thinks caused the error. See
Running make or Compilers Generally, for more information about using
the next-error command.

   In addition, you can kill the shell in which the makeinfo command is
running or make the shell buffer display its most recent output.

C-c C-m C-k
M-x makeinfo-kill-job
     Kill the currently running job created by makeinfo-region or
     makeinfo-buffer.

C-c C-m C-l
M-x makeinfo-recenter-output-buffer
     Redisplay the makeinfo shell buffer to display its most recent
     output.

(Note that the parallel commands for killing and recentering a TeX job
are C-c C-t C-k and C-c C-t C-l. See
                Texinfo Mode Printing
                .)

   You can specify options for makeinfo by setting the makeinfo-options
variable with either the M-x edit-options or the M-x set-variable command,
or by setting the variable in your .emacs initialization file.

   For example, you could write the following in your .emacs file:

     (setq makeinfo-options
           "--paragraph-indent=0 --no-split
            --fill-column=70 --verbose")

For more information, see
Editing Variable Values,
Examining and Setting Variables,
Init File, and

                Options for makeinfo
                 .

1.209   texi.info/texinfo-format commands

                The texinfo-format... Commands
==============================

In GNU Emacs in Texinfo mode, you can format part or all of a Texinfo
file with the texinfo-format-region command. This formats the current
region and displays the formatted text in a temporary buffer called
Info Region.

   Similarly, you can format a buffer with the texinfo-format-buffer
command. This command creates a new buffer and generates the Info file
in it. Typing C-x C-s will save the Info file under the name specified
by the @setfilename line which must be near the beginning of the
Texinfo file.

C-c C-e C-r

```
texinfo-format-region
     Format the current region for Info.

C-c C-e C-b
texinfo-format-buffer
     Format the current buffer for Info.
```

   The texinfo-format-region and texinfo-format-buffer commands provide
you with some error checking, and other functions can provide you with
further help in finding formatting errors. These procedures are
described in an appendix; see
                 Catching Mistakes
                 . However, the makeinfo
program is often faster and provides better error checking (see

                 makeinfo in Emacs
).

1.210   texi.info/Batch Formatting

```
Batch Formatting
================
```

   You can format Texinfo files for Info using batch-texinfo-format and
Emacs Batch mode. You can run Emacs in Batch mode from any shell,
including a shell inside of Emacs. (See
Command Line Switches and Arguments.)

   Here is the command to format all the files that end in .texinfo in
the current directory (where % is the shell prompt):

     % emacs -batch -funcall batch-texinfo-format *.texinfo

Emacs processes all the files listed on the command line, even if an
error occurs while attempting to format some of them.

   Run batch-texinfo-format only with Emacs in Batch mode as shown; it
is not interactive. It kills the Batch mode Emacs on completion.

   batch-texinfo-format is convenient if you lack makeinfo and want to
format several Texinfo files at once. When you use Batch mode, you
create a new Emacs process. This frees your current Emacs, so you can
continue working in it. (When you run texinfo-format-region or
texinfo-format-buffer, you cannot use that Emacs for anything else
until the command finishes.)

1.211   texi.info/Tag and Split Files

Tag Files and Split Files
==========================

   If a Texinfo file has more than 30,000 bytes, texinfo-format-buffer
automatically creates a tag table for its Info file; makeinfo always
creates a tag table. With a tag table, Info can jump to new nodes more
quickly than it can otherwise.

   In addition, if the Texinfo file contains more than about 70,000
bytes, texinfo-format-buffer and makeinfo split the large Info file
into shorter indirect subfiles of about 50,000 bytes each. Big files
are split into smaller files so that Emacs does not need to make a
large buffer to hold the whole of a large Info file; instead, Emacs
allocates just enough memory for the small, split off file that is
needed at the time. This way, Emacs avoids wasting memory when you run
Info. (Before splitting was implemented, Info files were always kept
short and include files were designed as a way to create a single,
large printed manual out of the smaller Info files. See
                 Include Files
                     ,
for more information. Include files are still used for very large
documents, such as 'The Emacs Lisp Reference Manual', in which each
chapter is a separate file.)

   When a file is split, Info itself makes use of a shortened version of
the original file that contains just the tag table and references to
the files that were split off. The split off files are called indirect
files.

   The split off files have names that are created by appending -1, -2,
-3 and so on to the file name specified by the @setfilename command.
The shortened version of the original file continues to have the name
specified by @setfilename.

   At one stage in writing this document, for example, the Info file
was saved as test-texinfo and that file looked like this:

     Info file: test-texinfo,   -*-Text-*-
     produced by texinfo-format-buffer
     from file: new-texinfo-manual.texinfo

     ^_
     Indirect:
     test-texinfo-1: 102
     test-texinfo-2: 50422
     test-texinfo-3: 101300
     ^_^L
     Tag table:
     (Indirect)
     Node: overview^?104
     Node: info file^?1271
     Node: printed manual^?4853
     Node: conventions^?6855
     ...

(But test-texinfo had far more nodes than are shown here.) Each of the

split off, indirect files, test-texinfo-1, test-texinfo-2, and
test-texinfo-3, is listed in this file after the line that says
Indirect:. The tag table is listed after the line that says Tag
table:.

   In the list of indirect files, the number following the file name
records the cumulative number of bytes in the preceding indirect files,
not counting the file list itself, the tag table, or the permissions
text in each file. In the tag table, the number following the node name
records the location of the beginning of the node, in bytes from the
beginning.

   If you are using texinfo-format-buffer to create Info files, you may
want to run the Info-validate command. (The makeinfo command does such
a good job on its own, you do not need Info-validate.) However, you
cannot run the M-x Info-validate node-checking command on indirect
files. For information on how to prevent files from being split and
how to validate the structure of the nodes, see
                Using Info-validate
                   .

1.212   texi.info/Install an Info File

                Installing an Info File
****

   Info files are usually kept in the info directory. (You can find
the location of this directory within Emacs by typing C-h i to enter
Info and then typing C-x C-f to see the full pathname to the info
directory.)

                Directory file
                        The top level menu for all Info files.

                New Info File
                        Listing a new info file.

                Other Info Directories
                    How to specify Info files that are
                            located in other directories.

1.213   texi.info/Directory file

                The dir File
============

For Info to work, the info directory must contain a file that serves
as a top level directory for the Info system. By convention, this file
is called dir. The dir file is itself an Info file. It contains the
top level menu for all the Info files in the system. The menu looks
like this:

```
    * Menu:

    * Info:     (info).      Documentation browsing system.
    * Emacs:    (emacs).     The extensible, self-documenting
                             text editor.
    * Texinfo: (texinfo).  With one source file, make
                             either a printed manual using
                             TeX or an Info file.
    ...
```

Each of these menu entries points to the 'Top' node of the Info file
that is named in parentheses. (The menu entry does not need to specify
the 'Top' node, since Info goes to the 'Top' node if no node name is
mentioned. See

                Nodes in Other Info Files
                .)

Thus, the Info entry points to the 'Top' node of the info file and
the Emacs entry points to the 'Top' node of the emacs file.

In each of the Info files, the 'Up' pointer of the 'Top' node refers
back to the dir file. For example, the line for the 'Top' node of the
Emacs manual looks like this in Info:

```
    File: emacs  Node: Top, Up: (DIR), Next: Distrib
```

(Note that in this case, the dir file name is written in upper case
letters--it can be written in either upper or lower case. Info has a
feature that it will change the case of the file name to lower case if
it cannot find the name as written.)

1.214   texi.info/New Info File

```
Listing a New Info File
=======================
```

To add a new Info file to your system, write a menu entry for it in
the menu in the dir file in the info directory. Also, move the new
Info file itself to the info directory. For example, if you were
adding documentation for GDB, you would write the following new entry:

```
    * GDB: (gdb).          The source-level C debugger.
```

The first part of the menu entry is the menu entry name, followed by a
colon. The second part is the name of the Info file, in parentheses,
followed by a period. The third part is the description.

   Conventionally, the name of an Info file has a .info extension.
Thus, you might list the name of the file like this:

     * GDB: (gdb.info).   The source-level C debugger.

However, Info will look for a file with a .info extension if it does
not find the file under the name given in the menu. This means that
you can refer to the file gdb.info as gdb, as shown in the first
example. This looks better.

1.215   texi.info/Other Info Directories

Info Files in Other Directories
===============================

   If an Info file is not in the info directory, there are two ways to
specify its location:

   * Write the pathname as the menu's second part, or;

   * Specify the info directory name in an environment variable in your
     .profile or .cshrc initialization file. (Only you and others with
     the same environment variable will be able to find Info files whose
     location is specified this way.)

   For example, to reach a test file in the ~bob/manuals directory, you
could add an entry like this to the menu in the dir file:

     * Test: (~bob/manuals/info-test). Bob's own test file.

In this case, the absolute file name of the info-test file is written
as the second part of the menu entry.

   Alternatively, you can tell Info where to look by setting the
INFOPATH environment variable in your .cshrc or .profile file.

   If you use sh or bash for your shell command interpreter, you must
set the INFOPATH environment variable in the .profile initialization
file; but if you use csh, you must set the variable in the .cshrc
initialization file. The two files require slightly different command
formats.

   * In a .cshrc file, you could set the INFOPATH variable as follows:

         setenv INFOPATH .:~bob/manuals:/gnu/emacs/info

   * In a .profile file, you would achieve the same effect by writing:

         INFOPATH=.:~bob/manuals:/gnu/emacs/info
         export INFOPATH

Either form would cause Info to look first in the current directory,
indicated by the ., then in the ~bob/manuals directory, and finally in
the /gnu/emacs/info directory (which is a common location for the

standard Info directory).

1.216 texi.info/Command List

                    * * * * * * * * * * * * * *

   Here is an alphabetical list of the @-commands in Texinfo. Square
brackets, [ ], indicate optional arguments; an ellipsis, ...,
indicates repeated text.

 @*
     Force a line break. Do not end a paragraph that uses @* with an
     @refill command. See
                 Line Breaks
                 .

 @.
     Stands for a period that really does end a sentence (usually after
     an end-of-sentence capital letter). See
                 Controlling Spacing
                 .

 @:
     Indicate to TeX that an immediately preceding period, question
     mark, exclamation mark, or colon does not end a sentence. Prevent
     TeX from inserting extra whitespace as it does at the end of a
     sentence. The command has no effect on the Info file output. See

                 Controlling Spacing
                 .

 @@
     Stands for @. See
                 Inserting @
                 .

     Stands for a left-hand brace, {. See

                 Inserting @ braces and periods
                 .

 @}
     Stands for a right-hand brace, }. See

                 Inserting @ braces and periods
                 .

 @appendix title
     Begin an appendix. The title appears in the table of contents of
     a printed manual. In Info, the title is underlined with
     asterisks. See
                 The @unnumbered and @appendix Commands
                 .

```
@appendixsec title
@appendixsection title
     Begin an appendix section within an appendix.  The section title
     appears in the table of contents of a printed manual.  In Info,
     the title is underlined with equal signs.   @appendixsection is a
     longer spelling of the  @appendixsec command.  See

                  Section Commands
                  .

@appendixsubsec title
     Begin an appendix subsection within an appendix.  The title appears
     in the table of contents of a printed manual.  In Info, the title
     is underlined with hyphens.  See
                  Subsection Commands
                  .

@appendixsubsubsec title
     Begin an appendix subsubsection within a subappendix.  The title
     appears in the table of contents of a printed manual.  In Info, the
     title is underlined with periods.  See
                  The 'subsub' Commands
                  .

@asis
     Used following  @table,  @ftable, and  @vtable to print the
     table's first column without highlighting ("as is").  See

                  Making a Two-column Table
                  .

@author author
     Typeset author flushleft and underline it.  See

                  The @title and @author Commands
                  .

@b{text }
     Print text in bold font.  No effect in Info.  See
                  Fonts
                  .

@bullet{}
     Generate a large round dot, or the closest possible thing to one.
     See
                  @bullet
                  .

@bye
     Stop formatting a file.  The formatters do not see the contents of
     a file following an  @bye command.  See
                  Ending a File
                  .

@c comment
     Begin a comment in Texinfo.  The rest of the line does not appear
```

in either the Info file or the printed manual. A synonym for
@comment. See
            General Syntactic Conventions
            .

@cartouche
    Highlight an example or quotation by drawing a box with rounded
    corners around it. Pair with @end cartouche. No effect in Info.
    See
            Drawing Cartouches Around Examples
            .)

@center line-of-text
    Center the line of text following the command. See
            @center
            .

@chapheading title
    Print a chapter-like heading in the text, but not in the table of
    contents of a printed manual. In Info, the title is underlined
    with asterisks. See
            @majorheading and @chapheading
            .

@chapter title
    Begin a chapter. The chapter title appears in the table of
    contents of a printed manual. In Info, the title is underlined
    with asterisks. See
            @chapter
            .

@cindex entry
    Add entry to the index of concepts. See

            Defining the Entries of an Index
            .

@cite{reference }
    Highlight the name of a book or other reference that lacks a
    companion Info file. See
            @cite
            .

@clear flag
    Unset flag, preventing the Texinfo formatting commands from
    formatting text between subsequent pairs of @ifset flag and @end
    ifset commands, and preventing @value{flag } from expanding to
    the value to which flag is set. See
            @set @clear @value
            .

@code{sample-code }
    Highlight text that is an expression, a syntactically complete
    token of a program, or a program name. See
            @code
            .

```
@comment comment
     Begin a comment in Texinfo.  The rest of the line does not appear
     in either the Info file or the printed manual.  A synonym for  @c.
     See
                 General Syntactic Conventions
                 .

@contents
     Print a complete table of contents.  Has no effect in Info, which
     uses menus instead.  See
                 Generating a Table of Contents
                 .

@copyright{}
     Generate a copyright symbol.  See
                 @copyright
                 .

@defcodeindex index-name
     Define a new index and its indexing command.  Print entries in an
     @code font.  See
                 Defining New Indices
                 .

@defcv category class name
     Format a description for a variable associated with a class in
     object-oriented programming.  Takes three arguments: the category
     of thing being defined, the class to which it belongs, and its
     name.  See
                 Definition Commands
                 .

@deffn category name arguments ...
     Format a description for a function, interactive command, or
     similar entity that may take arguments.   @deffn takes as
     arguments the category of entity being described, the name of this
     particular entity, and its arguments, if any.  See

                 Definition Commands
                 .

@defindex index-name
     Define a new index and its indexing command.  Print entries in a
     roman font.  See
                 Defining New Indices
                 .

@defivar class instance-variable-name
     Format a description for an instance variable in object-oriented
     programming.  The command is equivalent to  @defcv {Instance
     Variable} ....  See
                 Definition Commands
                 .

@defmac macro-name arguments ...
     Format a description for a macro.  The command is equivalent to
     @deffn Macro ....  See
```

```
                    Definition Commands
                    .

@defmethod class method-name arguments ...
     Format a description for a method in object-oriented programming.
     The command is equivalent to  @defop Method ....  Takes as
     arguments the name of the class of the method, the name of the
     method, and its arguments, if any.  See
                    Definition Commands
                    .

@defop category class name arguments ...
     Format a description for an operation in object-oriented
     programming.   @defop takes as arguments the overall name of the
     category of operation, the name of the class of the operation, the
     name of the operation, and its arguments, if any.  See

                    Definition Commands
                    .

@defopt option-name
     Format a description for a user option.  The command is equivalent
     to  @defvr {User Option} ....  See
                    Definition Commands
                    .

@defspec special-form-name arguments ...
     Format a description for a special form.  The command is
     equivalent to  @deffn {Special Form} ....  See
                    Definition Commands
                    .

@deftp category name-of-type attributes ...
     Format a description for a data type.   @deftp takes as arguments
     the category, the name of the type (which is a word like int or
     float), and then the names of attributes of objects of that type.
     See
                    Definition Commands
                    .

@deftypefn classification data-type name arguments ...
     Format a description for a function or similar entity that may take
     arguments and that is typed.   @deftypefn takes as arguments the
     classification of entity being described, the type, the name of
     the entity, and its arguments, if any.  See
                    Definition Commands
                    .

@deftypefun data-type function-name arguments ...
     Format a description for a function in a typed language.  The
     command is equivalent to  @deftypefn Function ....  See

                    Definition Commands
                    .

@deftypevr classification data-type name
     Format a description for something like a variable in a typed
```

```
     language--an entity that records a value.  Takes as arguments the
     classification of entity being described, the type, and the name of
     the entity.  See
                Definition Commands
                .

@deftypevar data-type variable-name
     Format a description for a variable in a typed language.  The
     command is equivalent to  @deftypevr Variable ....  See

                Definition Commands
                .

@defun function-name arguments ...
     Format a description for functions.  The command is equivalent to
     @deffn Function ....  See
                Definition Commands
                .

@defvar variable-name
     Format a description for variables.  The command is equivalent to
     @defvr Variable ....  See
                Definition Commands
                .

@defvr category name
     Format a description for any kind of variable.   @defvr takes as
     arguments the category of the entity and the name of the entity.
     See
                Definition Commands
                .

@dfn{term }
     Highlight the introductory or defining use of a term.  See
                @dfn
                .

@display
     Begin a kind of example.  Indent text, do not fill, do not select a
     new font.  Pair with  @end display.  See
                @display
                .

@dmn{dimension }
     Format a dimension.  Cause TeX to insert a narrow space before
     dimension.  No effect in Info.  Use for writing a number followed
     by an abbreviation of a dimension name, such as 12pt, written as
     12@dmn{pt}, with no space between the number and the  @dmn
     command.  See
                @dmn
                .

@dots{}
     Insert an ellipsis: ....  See
                @dots
                .
```

```
@emph{text }
     Highlight text; text is displayed in italics in printed output,
     and surrounded by asterisks in Info.  See
                  Emphasizing Text
                  .

@enumerate [number-or-letter]
     Begin a numbered list, using  @item for each entry.  Optionally,
     start list with number-or-letter.  Pair with  @end enumerate.  See

                  @enumerate
                  .

@equiv{}
     Indicate to the reader the exact equivalence of two forms with a
     glyph: ==.  See
                  Equivalence
                  .

@error{}
     Indicate to the reader with a glyph that the following text is an
     error message: error-->.  See
                  Error Glyph
                  .

@evenfooting [left] @| [center] @| [right]
     Specify page footings for even-numbered (left-hand) pages.  Not
     relevant to Info.  See
                  How to Make Your Own Headings
                  .

@evenheading [left] @| [center] @| [right]
     Specify page headings for even-numbered (left-hand) pages.  Not
     relevant to Info.  See
                  How to Make Your Own Headings
                  .

@everyfooting [left] @| [center] @| [right]
     Specify page footings for every page.  Not relevant to Info.  See

                  How to Make Your Own Headings
                  .

@everyheading [left] @| [center] @| [right]
     Specify page headings for every page.  Not relevant to Info.  See

                  How to Make Your Own Headings
                  .

@example
     Begin an example.  Indent text, do not fill, and select
     fixed-width font.  Pair with  @end example.  See
                  @example
                  .

@exdent line-of-text
     Remove any indentation a line might have.  See
```

```
                       Undoing the Indentation of a Line
                       .

@expansion{}
     Indicate the result of a macro expansion to the reader with a
     special glyph: ==>.  See
                  ==> Indicating an Expansion
                  .

@file{filename }
     Highlight the name of a file, buffer, node, or directory.  See

                  @file
                  .

@finalout
     Prevent TeX from printing large black warning rectangles beside
     over-wide lines.  See
                  Overfull hboxes
                  .

@findex entry
     Add entry to the index of functions.  See

                  Defining the Entries of an Index
                  .

@flushleft
     Left justify every line but leave the right end ragged.  Leave
     font as is.  Pair with  @end flushleft.  See

                  @flushleft and @flushright
                  .

@flushright
     Right justify every line but leave the left end ragged.  Leave
     font as is.  Pair with  @end flushright.  See

                  @flushleft and @flushright
                  .

@footnote{text-of-footnote }
     Enter a footnote.  Footnote text is printed at the bottom of the
     page by TeX; Info may format in either 'End' node or 'Separate'
     node style.  See
                  Footnotes
                  .

@footnotestyle style
     Specify an Info file's footnote style, either end for the end node
     style or separate for the separate node style.  See
                  Footnotes
                  .

@format
     Begin a kind of example.  Like  @example or  @display, but do not
```

```
          narrow the margins and do not select the fixed-width font.  Pair
          with  @end format.  See
                    @example
                    .
```

@ftable formatting-command

      Begin a two-column table, using @item for each entry.
      Automatically enter each of the items in the first column into the
      index of functions. Pair with @end ftable. The same as @table,
      except for indexing. See
                @ftable and @vtable
                .

@group

      Hold text together that must appear on one printed page. Pair with
       @end group. Not relevant to Info. See
                @group
                .

@heading title

      Print an unnumbered section-like heading in the text, but not in
      the table of contents of a printed manual. In Info, the title is
      underlined with equal signs. See
                Section Commands
                .

@headings on-off-single-double

      Turn page headings on or off, or specify single-sided or
      double-sided page headings for printing.   @headings on is
      synonymous with @headings double. See
                The @headings Command
                .

@i{text }

      Print text in italic font. No effect in Info. See
                Fonts
                .

@ifclear flag

      If flag is cleared, the Texinfo formatting commands format text
      between @ifclear flag and the following @end ifclear command.
      See
                @set @clear @value
                .

@ifinfo

      Begin a stretch of text that will be ignored by TeX when it
      typesets the printed manual. The text appears only in the Info
      file. Pair with @end ifinfo. See
                Conditionally Visible Text
                .

@ifset flag

      If flag is set, the Texinfo formatting commands format text
      between @ifset flag and the following @end ifset command. See

                @set @clear @value

.

@iftex
     Begin a stretch of text that will not appear in the Info file, but
     will be processed only by TeX. Pair with @end iftex. See

               Conditionally Visible Text
               .

@ignore
     Begin a stretch of text that will not appear in either the Info
     file or the printed output. Pair with @end ignore. See

               Comments and Ignored Text
               .

@include filename
     Incorporate the contents of the file filename into the Info file
     or printed document. See
               Include Files
               .

@inforef{node-name, [entry-name], info-file-name }
     Make a cross reference to an Info file for which there is no
     printed manual. See
               Cross references using @inforef
               .

\input macro-definitions-file
     Use the specified macro definitions file. This command is used
     only in the first line of a Texinfo file to cause TeX to make use
     of the texinfo macro definitions file. The backslash in \input is
     used instead of an @ because TeX does not properly recognize @
     until after it has read the definitions file. See

               The Texinfo File Header
               .

@item
     Indicate the beginning of a marked paragraph for @itemize and
     @enumerate; indicate the beginning of the text of a first column
     entry for @table, @ftable, and @vtable. See
               Lists and Tables
               .

@itemize mark-generating-character-or-command
     Produce a sequence of indented paragraphs, with a mark inside the
     left margin at the beginning of each paragraph. Pair with @end
     itemize. See
               @itemize
               .

@itemx
     Like @item but do not generate extra vertical space above the
     item text. See
               @itemx
               .

```
@kbd{keyboard-characters }
     Indicate text that consists of characters of input to be typed by
     users.  See
                  @kbd
                  .

@key{key-name }
     Highlight key-name, a conventional name for a key on a keyboard.
     See
                  @key
                  .

@kindex entry
     Add entry to the index of keys.  See

                  Defining the Entries of an Index
                  .

@lisp
     Begin an example of Lisp code.  Indent text, do not fill, and
     select fixed-width font.  Pair with  @end lisp.  See
                  @lisp
                  .

@majorheading  title
     Print a chapter-like heading in the text, but not in the table of
     contents of a printed manual.  Generate more vertical whitespace
     before the heading than the  @chapheading command.  In Info, the
     chapter heading line is underlined with asterisks.  See

                  @majorheading and @chapheading
                  .

@menu
     Mark the beginning of a menu of nodes in Info.  No effect in a
     printed manual.  Pair with  @end menu.  See
                  Menus
                  .

@minus{}
     Generate a minus sign.  See
                  @minus
                  .

@need n
     Start a new page in a printed manual if fewer than n mils
     (thousandths of an inch) remain on the current page.  See
                  @need
                  .

@node name, next, previous, up
     Define the beginning of a new node in Info, and serve as a locator
     for references for TeX.  See
                  @node
                  .
```

@noindent
    Prevent text from being indented as if it were a new paragraph.
    See
                @noindent
                .

@oddfooting [left] @| [center] @| [right]
    Specify page footings for odd-numbered (right-hand) pages. Not
    relevant to Info. See
                How to Make Your Own Headings
                .

@oddheading [left] @| [center] @| [right]
    Specify page headings for odd-numbered (right-hand) pages. Not
    relevant to Info. See
                How to Make Your Own Headings
                .

@page
    Start a new page in a printed manual. No effect in Info. See

                @page
                .

@paragraphindent indent
    Indent paragraphs by indent number of spaces; delete indentation
    if the value of indent is 0; and do not change indentation if
    indent is asis. See
                Paragraph Indenting
                .

@pindex entry
    Add entry to the index of programs. See

                Defining the Entries of an Index
                .

@point{}
    Indicate the position of point in a buffer to the reader with a
    glyph: -!-. See
                Indicating Point in a Buffer
                .

@print{}
    Indicate printed output to the reader with a glyph: -|. See

                Print Glyph
                .

@printindex index-name
    Print an alphabetized two-column index in a printed manual or
    generate an alphabetized menu of index entries for Info. See

                Printing Indices & Menus
                .

@pxref{node-name, [entry], [topic-or-title], [info-file], [manual]}

Make a reference that starts with a lower case 'see' in a printed
manual. Use within parentheses only. Do not follow command with a
punctuation mark. The Info formatting commands automatically
insert terminating punctuation as needed, which is why you do not
need to insert punctuation. Only the first argument is mandatory.
See
            @pxref
            .

@quotation
    Narrow the margins to indicate text that is quoted from another
    real or imaginary work. Write command on a line of its own. Pair
    with @end quotation. See
            @quotation
            .

@r{text }
    Print text in roman font. No effect in Info. See
            Fonts
            .

@ref{node-name, [entry], [topic-or-title], [info-file], [manual]}
    Make a reference. In a printed manual, the reference does not
    start with a 'See'. Follow command with a punctuation mark. Only
    the first argument is mandatory. See
            @ref
            .

@refill
    In Info, refill and indent the paragraph after all the other
    processing has been done. No effect on TeX, which always refills.
    This command is no longer needed, since all formatters now
    automatically refill. See
            Refilling Paragraphs
            .

@result{}
    Indicate the result of an expression to the reader with a special
    glyph: =>. See
            @result
            .

@samp{text }
    Highlight text that is a literal example of a sequence of
    characters. Used for single characters, for statements, and often
    for entire shell commands. See
            @samp
            .

@sc{text }
    Set text in a printed output in THE SMALL CAPS FONT and set text
    in the Info file in uppercase letters. See
            Smallcaps
            .

@section title
    Begin a section within a chapter. In a printed manual, the section

       title is numbered and appears in the table of contents. In Info,
       the title is underlined with equal signs. See
                  @section
                  .

@set flag [string]
       Make flag active, causing the Texinfo formatting commands to
       format text between subsequent pairs of @ifset flag and @end
       ifset commands. Optionally, set value of flag to string. See

                  @set @clear @value
                  .

@setchapternewpage on-off-odd
       Specify whether chapters start on new pages, and if so, whether on
       odd-numbered (right-hand) new pages. See
                  @setchapternewpage
                  .

@setfilename info-file-name
       Provide a name for the Info file. See

                  General Syntactic Conventions
                  .

@settitle title
       Provide a title for page headers in a printed manual. See

                  General Syntactic Conventions
                  .

@shortcontents
       Print a short table of contents. Not relevant to Info, which uses
       menus rather than tables of contents. A synonym for
       @summarycontents. See
                  Generating a Table of Contents
                  .

@smallbook
       Cause TeX to produce a printed manual in a 7 by 9.25 inch format
       rather than the regular 8.5 by 11 inch format. See

                  Printing Small Books
                  . Also, see
                  @smallexample and @smalllisp
                  .

@smallexample
       Indent text to indicate an example. Do not fill, select
       fixed-width font. In @smallbook format, print text in a smaller
       font than with @example. Pair with @end smallexample. See

                  @smallexample and @smalllisp
                  .

@smalllisp
       Begin an example of Lisp code. Indent text, do not fill, select

```
     fixed-width font.  In  @smallbook format, print text in a smaller
     font.  Pair with  @end smalllisp.  See

                   @smallexample and @smalllisp
                   .

@sp n
     Skip n blank lines.  See
                   @sp
                   .

@strong text
     Emphasize text by typesetting it in a bold font for the printed
     manual and by surrounding it with asterisks for Info.  See

                   Emphasizing Text
                   .

@subheading title
     Print an unnumbered subsection-like heading in the text, but not in
     the table of contents of a printed manual.  In Info, the title is
     underlined with hyphens.  See

                   @unnumberedsubsec @appendixsubsec @subheading
                   .

@subsection title
     Begin a subsection within a section.  In a printed manual, the
     subsection title is numbered and appears in the table of contents.
     In Info, the title is underlined with hyphens.  See
                   @subsection
                   .

@subsubheading title
     Print an unnumbered subsubsection-like heading in the text, but
     not in the table of contents of a printed manual.  In Info, the
     title is underlined with periods.  See
                   The 'subsub' Commands
                   .

@subsubsection title
     Begin a subsubsection within a subsection.  In a printed manual,
     the subsubsection title is numbered and appears in the table of
     contents.  In Info, the title is underlined with periods.  See

                   The 'subsub' Commands
                   .

@subtitle title
     In a printed manual, set a subtitle in a normal sized font flush to
     the right-hand side of the page.  Not relevant to Info, which does
     not have title pages.  See
                   @title @subtitle and @author Commands
                   .

@summarycontents
     Print a short table of contents.  Not relevant to Info, which uses
```

menus rather than tables of contents. A synonym for
@shortcontents. See
                Generating a Table of Contents
                .

@syncodeindex from-index into-index
    Merge the index named in the first argument into the index named in
    the second argument, printing the entries from the first index in
    @code font. See
                Combining Indices
                .

@synindex from-index into-index
    Merge the index named in the first argument into the index named in
    the second argument. Do not change the font of from-index
    entries. See
                Combining Indices
                .

@t{text }
    Print text in a fixed-width, typewriter-like font. No effect in
    Info. See
                Fonts
                .

@table formatting-command
    Begin a two-column table, using @item for each entry. Write each
    first column entry on the same line as @item. First column
    entries are printed in the font resulting from formatting-command.
    Pair with @end table. See
                Making a Two-column Table
                . Also see

                @ftable and @vtable
                , and
                @itemx
                .

@TeX{}
    Insert the logo TeX. See
                Inserting TeX and (C)
                .

@tex
    Enter TeX completely. Pair with @end tex. See

                Using Ordinary TeX Commands
                .

@thischapter
    In a heading or footing, stands for the number and name of the
    current chapter, in the format 'Chapter 1: Title'. See

                How to Make Your Own Headings
                .

@thischaptername

In a heading or footing, stands for the name of the current
chapter. See

How to Make Your Own Headings

.

`@thisfile`
In a heading or footing, stands for the name of the current
`@include` file. Does not insert anything if not within an
`@include` file. See

How to Make Your Own Headings

.

`@thispage`
In a heading or footing, stands for the current page number. See

How to Make Your Own Headings

.

`@thistitle`
In a heading or footing, stands for the name of the document, as
specified by the `@settitle` command. See

How to Make Your Own Headings

.

`@tindex entry`
Add entry to the index of data types. See

Defining the Entries of an Index

.

`@title title`
In a printed manual, set a title flush to the left-hand side of the
page in a larger than normal font and underline it with a black
rule. Not relevant to Info, which does not have title pages. See

The @title @subtitle and @author Commands

.

`@titlefont{text }`
In a printed manual, print text in a larger than normal font. Not
relevant to Info, which does not have title pages. See

The @titlefont @center and @sp Commands

.

`@titlepage`
Indicate to Texinfo the beginning of the title page. Write
command on a line of its own. Pair with `@end titlepage`. Nothing
between `@titlepage` and `@end titlepage` appears in Info. See

@titlepage

.

`@today{}`
Insert the current date, in '1 Jan 1900' style. See

How to Make Your Own Headings

.

@top title
    In a Texinfo file to be formatted with makeinfo, identify the
    topmost @node line in the file, which must be written on the line
    immediately preceding the @top command. Used for makeinfo's node
    pointer insertion feature. The title is underlined with
    asterisks. Both the @node line and the @top line normally
    should be enclosed by @ifinfo and @end ifinfo. In TeX and
    texinfo-format-buffer, the @top command is merely a synonym for
    @unnumbered. See
                Creating Pointers with makeinfo
                .

@unnumbered title
    In a printed manual, begin a chapter that appears without chapter
    numbers of any kind. The title appears in the table of contents
    of a printed manual. In Info, the title is underlined with
    asterisks. See
                @unnumbered and @appendix
                .

@unnumberedsec title
    In a printed manual, begin a section that appears without section
    numbers of any kind. The title appears in the table of contents
    of a printed manual. In Info, the title is underlined with equal
    signs. See
                Section Commands
                .

@unnumberedsubsec title
    In a printed manual, begin an unnumbered subsection within a
    chapter. The title appears in the table of contents of a printed
    manual. In Info, the title is underlined with hyphens. See

                @unnumberedsubsec @appendixsubsec @subheading
                .

@unnumberedsubsubsec title
    In a printed manual, begin an unnumbered subsubsection within a
    chapter. The title appears in the table of contents of a printed
    manual. In Info, the title is underlined with periods. See

                The 'subsub' Commands
                .

@value{flag }
    Replace flag with the value to which it is set by @set flag. See

                @set @clear @value
                .

@var{metasyntactic-variable }
    Highlight a metasyntactic variable, which is something that stands
    for another piece of text. See
                Indicating Metasyntactic Variables

                               .

@vindex entry
     Add entry to the index of variables. See

                    Defining the Entries of an Index
                          .

@vskip amount
     In a printed manual, insert whitespace so as to push text on the
     remainder of the page towards the bottom of the page. Used in
     formatting the copyright page with the argument 0pt plus 1filll.
     (Note spelling of filll.)   @vskip may be used only in contexts
     ignored for Info. See
                    The Copyright Page and Printed Permissions
                          .

@vtable formatting-command
     Begin a two-column table, using @item for each entry.
     Automatically enter each of the items in the first column into the
     index of variables. Pair with @end vtable. The same as @table,
     except for indexing. See
                    @ftable and @vtable
                          .

@w{text }
     Prevent text from being split across two lines. Do not end a
     paragraph that uses @w with an @refill command. In the Texinfo
     file, keep text on one line. See
                    @w
                          .

@xref{node-name, [entry], [topic-or-title], [info-file], [manual]}
     Make a reference that starts with 'See' in a printed manual.
     Follow command with a punctuation mark. Only the first argument is
     mandatory. See
                    @xref
                          .

1.217 texi.info/Tips

                    Tips and Hints
****

   Here are some tips for writing Texinfo documentation:

   * Write in the present tense, not in the past or the future.

   * Write actively! For example, write "We recommend that ..." rather
     than "It is recommended that ...".

   * Use 70 or 72 as your fill column. Longer lines are hard to read.

   * Include a copyright notice and copying permissions.

Index, index, index!
....

   Write many index entries, in different ways. Readers like indices;
they are helpful and convenient.

   Although it is easiest to write index entries as you write the body
of the text, some people prefer to write entries afterwards. In either
case, write an entry before the paragraph to which it applies. This
way, an index entry points to the first page of a paragraph that is
split across pages.

   Here are more hints we have found valuable:

   * Write each index entry differently, so each entry refers to a
     different place in the document. The index of an Info file lists
     only one location for each entry.

   * Write index entries only where a topic is discussed significantly.
     For example, it is not useful to index "debugging information" in
     a chapter on reporting bugs. Someone who wants to know about
     debugging information will certainly not find it in that chapter.

   * Consistently capitalize the first word of every index entry, or
     else use lower case. According to convention, you should
     capitalize the first word of an index entry. However, this
     practice may make an index look crowded. Some writers prefer
     lower case. Regardless of which you prefer, choose one style and
     stick to it. Mixing the two styles looks bad.

   * Always capitalize or use upper case for those words in an index for
     which this is proper, such as names of countries or acronyms.

   * Write the indexing commands that refer to a whole section
     immediately after the section command, and write the indexing
     commands that refer to the paragraph before the paragraph.

     In the example that follows, a blank line comes after the index
     entry for "Leaping":

          @section The Dog and the Fox
          @cindex Jumping, in general
          @cindex Leaping

          @cindex Dog, lazy, jumped over
          @cindex Lazy dog jumped over
          @cindex Fox, jumps over dog
          @cindex Quick fox jumps over dog
          The quick brown fox jumps over the lazy dog.

   (Note that the example shows entries for the same concept that are
   written in different ways--Lazy dog, and Dog, lazy--so readers can
   look up the concept in different ways.)

Blank lines

....

   * Insert a blank line between a sectioning command and the first
     following sentence or paragraph, or between the indexing commands
     associated with the sectioning command and the first following
     sentence or paragraph, as shown in the tip on indexing.
     Otherwise, a formatter may fold title and paragraph together.

   * Always insert a blank line before an @table command and after an
     @end table command; but never insert a blank line after an @table
     command or before an @end table command.

     For example,

          Types of fox:

          @table @samp
          @item Quick
          Jump over lazy dogs.

          @item Brown
          Also jump over lazy dogs.
          @end table
          @noindent
          On the other hand, ...

     Insert blank lines before and after @itemize ... @end itemize
     and @enumerate ... @end enumerate in the same way.

Complete phrases
....

   Complete phrases are easier to read than ...

   * Write entries in an itemized list as complete sentences; or at
     least, as complete phrases. Incomplete expressions ... awkward
     ... like this.

   * Write the prefatory sentence or phrase for a multi-item list or
     table as a complete expression. Do not write "You can set:";
     instead, write "You can set these variables:". The former
     expression sounds cut off.

Editions, dates and versions
....

   Write the edition and version numbers and date in three places in
every manual:

  1. In the first @ifinfo section, for people reading the Texinfo file.

  2. In the @titlepage section, for people reading the printed manual.

  3. In the 'Top' node, for people reading the Info file.

Also, it helps to write a note before the first @ifinfo section to
explain what you are doing.

For example:

```
@c ===> NOTE! <==
@c Specify the edition and version numbers and date
@c in *three* places:
@c  1. First ifinfo section  2. title page  3. top node
@c To find the locations, search for !!set

@ifinfo
@c !!set edition, date, version
This is Edition 4.03, January 1992,
of the @cite{GDB Manual} for GDB Version 4.3.
...
```

--or use @set and @value (see
                @value Example
).

Definition Commands
....

   Definition commands are @deffn, @defun, @defmac, and the like,
and enable you to write descriptions in a uniform format.

   * Write just one definition command for each entity you define with a
     definition command. The automatic indexing feature creates an
     index entry that leads the reader to the definition.

   * Use @table ... @end table in an appendix that contains a summary
     of functions, not @deffn or other definition commands.

Capitalization
....

   * Capitalize Texinfo; it is a name. Do not write the x or i in
     upper case.

   * Capitalize Info; it is a name.

   * Write TeX using the @TeX{} command. Note the uppercase T and X.
     This command causes the formatters to typeset the name according
     to the wishes of Donald Knuth, who wrote TeX.

Spaces
......

   Do not use spaces to format a Texinfo file, except inside of
   For example, TeX fills the following:

```
@kbd{C-x v}
@kbd{M-x vc-next-action}
    Perform the next logical operation
    on the version-controlled file
    corresponding to the current buffer.
```

so it looks like this:

   'C-x v' 'M-x vc-next-action' Perform the next logical operation on
   the version-controlled file corresponding to the current buffer.

In this case, the text should be formatted with @table, @item, and
....

   * Use @code around Lisp symbols, including command names. For
     example,

          The main function is @code{vc-next-action}, ...

   * Avoid putting letters such as s immediately after an @code. Such
     letters look bad.

   * Use @var around meta-variables. Do not write angle brackets
     around them.

   * Use three hyphens in a row, --, to indicate a long dash. TeX
     typesets these as a long dash and the Info formatters reduce three
     hyphens to two.

Periods Outside of Quotes
....

   Place periods and other punctuation marks outside of quotations,
unless the punctuation is part of the quotation. This practice goes
against convention, but enables the reader to distinguish between the
contents of the quotation and the whole passage.

   For example, you should write the following sentence with the period
outside the end quotation marks:

          Evidently, au is an abbreviation for ``author''.

since au does not serve as an abbreviation for author. (with a period
following the word).

Introducing New Terms
....

   * Introduce new terms so that a user who does not know them can
     understand them from context; or write a definition for the term.

     For example, in the following, the terms "check in", "register" and
     "delta" are all appearing for the first time; the example sentence
     should be rewritten so they are understandable.

          The major function assists you in checking in a file to your
          version control system and registering successive sets of
          changes to it as deltas.

   * Use the @dfn command around a word being introduced, to indicate
     that the user should not expect to know the meaning already, and
     should expect to learn the meaning from this passage.

......

Absolutely never use @pxref except in the special context for which
it is designed: inside parentheses, with the closing parenthesis
following immediately after the closing brace. One formatter
automatically inserts closing punctuation and the other does not. This
means that the output looks right both in printed output and in an Info
file, but only when the command is used inside parentheses.

Invoking from a Shell
....

   You can invoke programs such as Emacs, GCC, and GAWK from a shell.
The documentation for each program should contain a section that
describes this. Unfortunately, if the node names and titles for these
sections are all different, readers find it hard to search for the
section.

   Name such sections with a phrase beginning with the word
'Invoking ...', as in 'Invoking Emacs'; this way users can find the
section easily.

ANSI C Syntax
....

   When you use @example to describe a C function's calling
conventions, use the ANSI C syntax, like this:

        void dld_init (char *@var{path});

And in the subsequent discussion, refer to the argument values by
writing the same argument names, again highlighted with @var.

   Avoid the obsolete style that looks like this:

        #include <dld.h>

        dld_init (path)
        char *path;

   Also, it is best to avoid writing #include above the declaration
just to indicate that the function is declared in a header file. The
practice may give the misimpression that the #include belongs near the
declaration of the function. Either state explicitly which header file
holds the declaration or, better yet, name the header file used for a
group of functions at the beginning of the section that describes the
functions.

Bad Examples
....

   Here are several examples of bad writing to avoid:

   In this example, say, " ... you must @dfn {check in} the new
version." That flows better.

        When you are done editing the file, you must perform a @dfn
        {check in}.

   In the following example, say, "... makes a unified interface such
as VC mode possible."

   SCCS, RCS and other version-control systems all perform similar
   functions in broadly similar ways (it is this resemblance which
   makes a unified control mode like this possible).

   And in this example, you should specify what 'it' refers to:

   If you are working with other people, it assists in coordinating
   everyone's changes so they do not step on each other.

And Finally ...
....

   * Pronounce TeX as if the X were a Greek 'chi', as the last sound in
     the name 'Bach'. But pronounce Texinfo as in 'speck': teckinfo.

   * Write notes for yourself at the very end of a Texinfo file after
     the @bye. None of the formatters process text after the @bye;
     it is as if the text were within @ignore ...   @end ignore.

1.218   texi.info/Sample Texinfo File

                A Sample Texinfo File
****

   Here is a complete, short sample Texinfo file, without any
commentary. You can see this file, with comments, in the first chapter.
See
                A Short Sample Texinfo File
                 .

     \input texinfo   @c -*-texinfo-*-
     @c %**start of header
     @setfilename sample.info
     @settitle Sample Document
     @c %**end of header

     @setchapternewpage odd

     @ifinfo
     This is a short example of a complete Texinfo file.

     Copyright 1990 Free Software Foundation, Inc.
     @end ifinfo

     @titlepage
     @sp 10
     @comment The title is printed in a large font.
     @center @titlefont{Sample Title}

```
@c The following two commands start the copyright page.
@page
@vskip 0pt plus 1filll
Copyright @copyright{} 1990 Free Software Foundation, Inc.
@end titlepage

@node    Top,        First Chapter, (dir),     (dir)
@comment node-name, next,           previous, up

@menu
* First Chapter::    The first chapter is the
                     only chapter in this sample.
* Concept Index::    This index has two entries.
@end menu

@node    First Chapter, Concept Index, Top,     Top
@comment node-name,     next,          previous, up
@chapter First Chapter
@cindex Sample index entry

This is the contents of the first chapter.
@cindex Another sample index entry

Here is a numbered list.

@enumerate
@item
This is the first item.

@item
This is the second item.
@end enumerate

The @code{makeinfo} and @code{texinfo-format-buffer}
commands transform a Texinfo file such as this into
an Info file; and @TeX{} typesets it for a printed
manual.

@node    Concept Index,    , First Chapter, Top
@comment node-name,    next, previous,      up
@unnumbered Concept Index

@printindex cp

@contents
@bye
```

1.219 texi.info/Sample Permissions

```
              Sample Permissions
******************
```

   Texinfo files should contain sections that tell the readers that they

have the right to copy and distribute the Texinfo file, the Info file,
and the printed manual.

   Also, if you are writing a manual about software, you should explain
that the software is free and either include the GNU General Public
License (GPL) or provide a reference to it. See Distribution, for an
example of the text that could be used in the software "Distribution",
"General Public License", and "NO WARRANTY" sections of a document.
See
                    Texinfo Copying Conditions
                  , for an example of a brief explanation
of how the copying conditions provide you with rights.

                    Inserting Permissions
                         How to put permissions in your document.

                    ifinfo Permissions
                           Sample ifinfo copying permissions.

                    Titlepage Permissions
                           Sample Titlepage copying permissions.

1.220   texi.info/Inserting Permissions

Inserting Permissions
=====================

   In a Texinfo file, the first @ifinfo section usually begins with a
line that says what the file documents. This is what a person reading
the unprocessed Texinfo file or using the advanced Info command g *
sees first. See Advanced Info commands, for more information. (A
reader using the regular Info commands usually starts reading at the
first node and skips this first section, which is not in a node.)

   In the @ifinfo section, the summary sentence is followed by a
copyright notice and then by the copying permission notice. One of the
copying permission paragraphs is enclosed in @ignore and @end ignore
commands. This paragraph states that the Texinfo file can be processed
through TeX and printed, provided the printed manual carries the proper
copying permission notice. This paragraph is not made part of the Info
file since it is not relevant to the Info file; but it is a mandatory
part of the Texinfo file since it permits people to process the Texinfo
file in TeX and print the results.

   In the printed manual, the Free Software Foundation copying
permission notice follows the copyright notice and publishing
information and is located within the region delineated by the
is exactly the same as the notice in the @ifinfo section except that
the paragraph enclosed in @ignore and @end ignore commands is not
part of the notice.

To make it simple to insert a permission notice into each section of the Texinfo file, sample permission notices for each section are reproduced in full below.

Note that you may need to specify the correct name of a section mentioned in the permission notice. For example, in 'The GDB Manual', the name of the section referring to the General Public License is called the "GDB General Public License", but in the sample shown below, that section is referred to generically as the "GNU General Public License". If the Texinfo file does not carry a copy of the General Public License, leave out the reference to it, but be sure to include the rest of the sentence.

1.221 texi.info/ifinfo Permissions

```
ifinfo Copying Permissions
==========================
```

   In the @ifinfo section of a Texinfo file, the standard Free Software Foundation permission notice reads as follows:

```
    This file documents ...

    Copyright 1992 Free Software Foundation, Inc.

    Permission is granted to make and distribute verbatim
    copies of this manual provided the copyright notice and
    this permission notice are preserved on all copies.

    @ignore
    Permission is granted to process this file through TeX
    and print the results, provided the printed document
    carries a copying permission notice identical to this
    one except for the removal of this paragraph (this
    paragraph not being relevant to the printed manual).

    @end ignore
    Permission is granted to copy and distribute modified
    versions of this manual under the conditions for
    verbatim copying, provided also that the sections
    entitled ``Copying'' and ``GNU General Public License''
    are included exactly as in the original, and provided
    that the entire resulting derived work is distributed
    under the terms of a permission notice identical to this
    one.

    Permission is granted to copy and distribute
    translations of this manual into another language,
    under the above conditions for modified versions,
    except that this permission notice may be stated in a
    translation approved by the Free Software Foundation.
```

1.222   texi.info/Titlepage Permissions

```
Titlepage Copying Permissions
=============================
```

   In the @titlepage section of a Texinfo file, the standard Free
Software Foundation copying permission notice follows the copyright
notice and publishing information. The standard phrasing is as follows:

```
    Permission is granted to make and distribute verbatim
    copies of this manual provided the copyright notice and
    this permission notice are preserved on all copies.

    Permission is granted to copy and distribute modified
    versions of this manual under the conditions for
    verbatim copying, provided also that the sections
    entitled ``Copying'' and ``GNU General Public License''
    are included exactly as in the original, and provided
    that the entire resulting derived work is distributed
    under the terms of a permission notice identical to this
    one.

    Permission is granted to copy and distribute
    translations of this manual into another language,
    under the above conditions for modified versions,
    except that this permission notice may be stated in a
    translation approved by the Free Software Foundation.
```

1.223   texi.info/Include Files

```
                  Include Files
*************
```

   When TeX or an Info formatting command sees an @include command in
a Texinfo file, it processes the contents of the file named by the
command and incorporates them into the DVI or Info file being created.
Index entries from the included file are incorporated into the indices
of the output file.

   Include files let you keep a single large document as a collection of
conveniently small parts.

```
                Using Include Files

```

1.224   texi.info/Using Include Files

```
How to Use Include Files
========================
```

   To include another file within a Texinfo file, write the @include
command at the beginning of a line and follow it on the same line by
the name of a file to be included. For example:

```
    @include buffers.texi
```

   An included file should simply be a segment of text that you expect
to be included as is into the overall or outer Texinfo file; it should
not contain the standard beginning and end parts of a Texinfo file. In
particular, you should not start an included file with a line saying
\input texinfo; if you do, that phrase is inserted into the output file
as is. Likewise, you should not end an included file with an @bye
command; nothing after @bye is formatted.

   In the past, you were required to write an @setfilename line at the
beginning of an included file, but no longer. Now, it does not matter
whether you write such a line. If an @setfilename line exists in an
included file, it is ignored.

   Conventionally, an included file begins with an @node line that is
followed by an @chapter line. Each included file is one chapter.
This makes it easy to use the regular node and menu creating and
updating commands to create the node pointers and menus within the
included file. However, the simple Emacs node and menu creating and
updating commands do not work with multiple Texinfo files. Thus you
cannot use these commands to fill in the 'Next', 'Previous', and 'Up'
pointers of the @node line that begins the included file. Also, you
cannot use the regular commands to create a master menu for the whole
file. Either you must insert the menus and the 'Next', 'Previous', and
'Up' pointers by hand, or you must use the GNU Emacs Texinfo mode
command, texinfo-multiple-files-update, that is designed for @include
files.

1.225   texi.info/texinfo-multiple-files-update

```
texinfo-multiple-files-update
=============================
```

   GNU Emacs Texinfo mode provides a command to handle included files
called texinfo-multiple-files-update. This command creates or updates
'Next', 'Previous', and 'Up' pointers of included files as well as
those in the outer or overall Texinfo file, and it creates or updates a
main menu in the outer file. Depending whether you call it with
optional arguments, the command updates only the pointers in the first
M-x texinfo-multiple-files-update
        Called without any arguments:

          – Create or update the 'Next', 'Previous', and 'Up' pointers of
            the first @node line in each file included in an outer or
            overall Texinfo file.

          – Create or update the 'Top' level node pointers of the outer or
            overall file.

          – Create or update a main menu in the outer file.

C-u M-x texinfo-multiple-files-update
        Called with C-u as a prefix argument:

          – Create or update pointers in the first @node line in each
            included file.

          – Create or update the 'Top' level node pointers of the outer
            file.

          – Create and insert a master menu in the outer file. The
            master menu is made from all the menus in all the included
            files.

C-u 8 M-x texinfo-multiple-files-update
        Called with a numeric prefix argument, such as C-u 8:

          – Create or update all the 'Next', 'Previous', and 'Up' pointers
            of all the included files.

          – Create or update all the menus of all the included files.

          – Create or update the 'Top' level node pointers of the outer or
            overall file.

          – And then create a master menu in the outer file. This is
            similar to invoking texinfo-master-menu with an argument when
            you are working with just one file.

   Note the use of the prefix argument in interactive use: with a
regular prefix argument, just C-u, the texinfo-multiple-files-update
command inserts a master menu; with a numeric prefix argument, such as
C-u 8, the command updates every pointer and menu in all the files and
then inserts a master menu.

1.226   texi.info/Include File Requirements

```
Include File Requirements
=========================
```

   If you plan to use the texinfo-multiple-files-update command, the
outer Texinfo file that lists included files within it should contain
nothing but the beginning and end parts of a Texinfo file, and a number
of @include commands listing the included files. It should not even
include indices, which should be listed in an included file of their
own.

   Moreover, each of the included files must contain exactly one highest
level node (conventionally, @chapter or equivalent), and this node
must be the first node in the included file. Furthermore, each of
these highest level nodes in each included file must be at the same
hierarchical level in the file structure. Usually, each is an
each included file contains one, and only one, chapter or
equivalent-level node.

   The outer file should contain only one node, the 'Top' node. It
should not contain any nodes besides the single 'Top' node. The
texinfo-multiple-files-update command will not process them.

1.227   texi.info/Sample Include File

```
Sample File with  @include
==========================
```

   Here is an example of a complete outer Texinfo file with @include
files within it before running texinfo-multiple-files-update, which
would insert a main or master menu:

```
    \input texinfo @c -*-texinfo-*-
    @setfilename  include-example.info
    @settitle Include Example

    @setchapternewpage odd
    @titlepage
    @sp 12
    @center @titlefont{Include Example}
    @sp 2
    @center by Whom Ever

    @page
    @vskip 0pt plus 1filll
    Copyright @copyright{} 1990 Free Software Foundation, Inc.
    @end titlepage

    @ifinfo
    @node Top, First, (dir), (dir)
    @top Master Menu
    @end ifinfo
```

```
    @include foo.texinfo
    @include bar.texinfo
    @include concept-index.texinfo

    @summarycontents
    @contents

    @bye
```

   An included file, such as foo.texinfo, might look like this:

```
    @node First, Second, , Top
    @chapter First Chapter

    Contents of first chapter ...
```

   The full contents of concept-index.texinfo might be as simple as
this:

```
    @node Concept Index, , Second, Top
    @unnumbered Concept Index

    @printindex cp
```

   The outer Texinfo source file for 'The GNU Emacs Lisp Reference
Manual' is named elisp.texi. This outer file contains a master menu
with 417 entries and a list of 41 @include files.

1.228   texi.info/Include Files Evolution

```
                Evolution of Include Files
==========================
```

   When Info was first created, it was customary to create many small
Info files on one subject. Each Info file was formatted from its own
Texinfo source file. This custom meant that Emacs did not need to make
a large buffer to hold the whole of a large Info file when someone
wanted information; instead, Emacs allocated just enough memory for the
small Info file that contained the particular information sought. This
way, Emacs could avoid wasting memory.

   References from one file to another were made by referring to the
file name as well as the node name. (See
                Referring to Other Info Files
                .
Also, see
                @xref with Four and Five Arguments
                .)

   Include files were designed primarily as a way to create a single,
large printed manual out of several smaller Info files. In a printed
manual, all the references were within the same document, so TeX could
automatically determine the references' page numbers. The Info

formatting commands used include files only for creating joint indices;
each of the individual Texinfo files had to be formatted for Info
individually. (Each, therefore, required its own @setfilename line.)

   However, because large Info files are now split automatically, it is
no longer necessary to keep them small.

   Nowadays, multiple Texinfo files are used mostly for large documents,
such as 'The GNU Emacs Lisp Reference Manual', and for projects in
which several different people write different sections of a document
simultaneously.

   In addition, the Info formatting commands have been extended to work
with the @include command so as to create a single large Info file
that is split into smaller files if necessary. This means that you can
write menus and cross references without naming the different Texinfo
files.

1.229   texi.info/Headings

                Page Headings
****

   Most printed manuals contain headings along the top of every page
except the title and copyright pages. Some manuals also contain
footings. (Headings and footings have no meaning to Info, which is not
paginated.)

                 Headings Introduced
                        Conventions for using page headings.

                 Heading Format
                          Standard page heading formats.

                 Heading Choice

                 Custom Headings
                          How to create your own headings and footings.

1.230   texi.info/Headings Introduced

Headings Introduced
===================

   Texinfo provides standard page heading formats for manuals that are

printed on one side of each sheet of paper and for manuals that are
printed on both sides of the paper. Usually, you will use one or other
of these formats, but you can specify your own format, if you wish.

   In addition, you can specify whether chapters should begin on a new
page, or merely continue the same page as the previous chapter; and if
chapters begin on new pages, you can specify whether they must be
odd-numbered pages.

   By convention, a book is printed on both sides of each sheet of
paper. When you open a book, the right-hand page is odd-numbered, and
chapters begin on right-hand pages--a preceding left-hand page is left
blank if necessary. Reports, however, are often printed on just one
side of paper, and chapters begin on a fresh page immediately following
the end of the preceding chapter. In short or informal reports,
chapters often do not begin on a new page at all, but are separated
from the preceding text by a small amount of whitespace.

   The @setchapternewpage command controls whether chapters begin on
new pages, and whether one of the standard heading formats is used. In
addition, Texinfo has several heading and footing commands that you can
use to generate your own heading and footing formats.

   In Texinfo, headings and footings are single lines at the tops and
bottoms of pages; you cannot create multiline headings or footings.
Each header or footer line is divided into three parts: a left part, a
middle part, and a right part. Any part, or a whole line, may be left
blank. Text for the left part of a header or footer line is set
flushleft; text for the middle part is centered; and, text for the
right part is set flushright.

1.231   texi.info/Heading Format

```
Standard Heading Formats
========================
```

   Texinfo provides two standard heading formats, one for manuals
printed on one side of each sheet of paper, and the other for manuals
printed on both sides of the paper.

   By default, nothing is specified for the footing of a Texinfo file,
so the footing remains blank.

   The standard format for single-sided printing consists of a header
line in which the left-hand part contains the name of the chapter, the
central part is blank, and the right-hand part contains the page number.

   A single-sided page looks like this:

```
         _____
        |                       |
        | chapter   page number |
        |                       |
        | Start of text ...     |
```

```
           | ...                   |
           |                       |
```

   The standard format for two-sided printing depends on whether the
page number is even or odd. By convention, even-numbered pages are on
the left- and odd-numbered pages are on the right. (TeX will adjust the
widths of the left- and right-hand margins. Usually, widths are
correct, but during double-sided printing, it is wise to check that
pages will bind properly--sometimes a printer will produce output in
which the even-numbered pages have a larger right-hand margin than the
odd-numbered pages.)

   In the standard double-sided format, the left part of the left-hand
(even-numbered) page contains the page number, the central part is
blank, and the right part contains the title (specified by the
page contains the name of the chapter, the central part is blank, and
the right part contains the page number.

   Two pages, side by side as in an open book, look like this:

```
     _____       _____
    |                       |     |                       |
    | page number     title |     | chapter   page number |
    |                       |     |                       |
    | Start of text ...     |     | More  text ...         |
    | ...                   |     | ...                   |
    |                       |     |                       |
```

The chapter name is preceded by the word Chapter, the chapter number
and a colon. This makes it easier to keep track of where you are in
the manual.

1.232   texi.info/Heading Choice

```
              Specifying the Type of Heading
==============================
```

   TeX does not begin to generate page headings for a standard Texinfo
file until it reaches the @end titlepage command. Thus, the title and
copyright pages are not numbered. The @end titlepage command causes
TeX to begin to generate page headings according to a standard format
specified by the @setchapternewpage command that precedes the
   There are four possibilities:

No @setchapternewpage command
     Cause TeX to specify the single-sided heading format, with chapters
     on new pages. This is the same as @setchapternewpage on.

 @setchapternewpage on
     Specify the single-sided heading format, with chapters on new
     pages.

 @setchapternewpage off
     Cause TeX to start a new chapter on the same page as the last page

of the preceding chapter, after skipping some vertical whitespace.
Also cause TeX to typeset for single-sided printing. (You can
override the headers format with the @headings double command; see

            The @headings Command
            .)

 @setchapternewpage odd
     Specify the double-sided heading format, with chapters on new
     pages.

Texinfo lacks an @setchapternewpage even command.

1.233   texi.info/Custom Headings

                How to Make Your Own Headings
==============================

   You can use the standard headings provided with Texinfo or specify
your own.

   Texinfo provides six commands for specifying headings and footings.
The @everyheading command and @everyfooting command generate page
headers and footers that are the same for both even- and odd-numbered
pages. The @evenheading command and @evenfooting command generate
headers and footers for even-numbered (left-hand) pages; and the
footers for odd-numbered (right-hand) pages.

   Write custom heading specifications in the Texinfo file immediately
after the @end titlepage command. Enclose your specifications between
 @iftex and @end iftex commands since the texinfo-format-buffer
command may not recognize them. Also, you must cancel the predefined
heading commands with the @headings off command before defining your
own specifications.

   Here is how to tell TeX to place the chapter name at the left, the
page number in the center, and the date at the right of every header
for both even- and odd-numbered pages:

     @iftex
     @headings off
     @everyheading @thischapter @| @thispage @| @today{}
     @end iftex

You need to divide the left part from the central part and the central
part from the right had part by inserting @| between parts.
Otherwise, the specification command will not be able to tell where the
text for one part ends and the next part begins.

   Each part can contain text or @-commands. The text is printed as if
the part were within an ordinary paragraph in the body of the page.
The @-commands replace themselves with the page number, date, chapter
name, or whatever.

   Here are the six heading and footing commands:

 @everyheading left @| center @| right
 @everyfooting left @| center @| right
     The 'every' commands specify the format for both even- and
     odd-numbered pages. These commands are for documents that are
     printed on one side of each sheet of paper, or for documents in
     which you want symmetrical headers or footers.

 @evenheading left @| center @| right
 @oddheading left @| center @| right
 @evenfooting left @| center @| right
 @oddfooting left @| center @| right
     The 'even' and 'odd' commands specify the format for even-numbered
     pages and odd-numbered pages. These commands are for books and
     manuals that are printed on both sides of each sheet of paper.

   Use the @this... series of @-commands to provide the names of
chapters and sections and the page number. You can use the @this...
commands in the left, center, or right portions of headers and footers,
or anywhere else in a Texinfo file so long as they are between @iftex
and @end iftex commands.

   Here are the @this... commands:

 @thispage
     Expands to the current page number.

 @thischaptername
     Expands to the name of the current chapter.

 @thischapter
     Expands to the number and name of the current chapter, in the
     format 'Chapter 1: Title'.

 @thistitle
     Expands to the name of the document, as specified by the
     @settitle command.

 @thisfile
     For @include files only: expands to the name of the current
     @include file. If the current Texinfo source file is not an
     @include file, this command has no effect. This command does not
     provide the name of the current Texinfo source file unless it is
     an @include file. (See
                 Include Files
                , for more information about
      @include files.)

You can also use the @today{} command, which expands to the current
date, in '1 Jan 1900' format.

   Other @-commands and text are printed in a header or footer just as
if they were in the body of a page. It is useful to incorporate text,
particularly when you are writing drafts:

```
    @iftex
    @headings off
    @everyheading @emph{Draft!} @| @thispage @| @thischapter
    @everyfooting @| @| Version: 0.27: @today{}
    @end iftex
```

   Beware of overlong titles: they may overlap another part of the
header or footer and blot it out.

1.234   texi.info/Catching Mistakes

                    Formatting Mistakes
****

   Besides mistakes in the content of your documentation, there are two
kinds of mistake you can make with Texinfo: you can make mistakes with
and chapters.

   Emacs has two tools for catching the @-command mistakes and two for
catching structuring mistakes.

   For finding problems with @-commands, you can run TeX or a region
formatting command on the region that has a problem; indeed, you can
run these commands on each region as you write it.

   For finding problems with the structure of nodes and chapters, you
can use C-c C-s (texinfo-show-structure) and the related occur command
and you can use the M-x Info-validate command.

                    makeinfo preferred
                            makeinfo finds errors.

                Debugging with Info
                        How to catch errors with Info formatting.

                Debugging with TeX
                        How to catch errors with TeX formatting.

                Using texinfo-show-structure
                  How to use texinfo-show-structure.

                Using occur
                                How to list all lines containing a pattern.

                Running Info-Validate
                        How to find badly referenced nodes.

1.235   texi.info/makeinfo preferred

```
makeinfo Find Errors
====================
```

   The makeinfo program does an excellent job of catching errors and
reporting them--far better than either the texinfo-format-region or the
texinfo-format-buffer command. In addition, the various functions for
automatically creating and updating node pointers and menus remove many
opportunities for human error.

   If you can, use the updating commands to create and insert pointers
and menus. These prevent many errors. Then use makeinfo (or its
Texinfo mode manifestations, makeinfo-region and makeinfo-buffer) to
format your file and check for other errors. This is the best way to
work with Texinfo. But if you cannot use makeinfo, or your problem is
very puzzling, then you may want to use the tools described in this
appendix.

1.236   texi.info/Debugging with Info

```
Catching Errors with Info Formatting
====================================
```

   After you have written part of a Texinfo file, you can use the
texinfo-format-region or the makeinfo-region command to see whether the
region formats properly.

   Most likely, however, you are reading this section because for some
reason you cannot use the makeinfo-region command; therefore, the rest
of this section presumes that you are using texinfo-format-region.

   If you make a mistake with an @-command, texinfo-format-region will
stop processing at or after the error and display an error message. To
see where in the buffer the error occurred, switch to the *Info Region*
buffer; the cursor will be in a position that is after the location of
the error. Also, the text will not be formatted after the place where
the error occurred (or more precisely, where it was detected).

   For example, if you accidentally end a menu with the command @end
menus with an 's' on the end, instead of with @end menu, you will see
an error message that says:

     @end menus is not handled by texinfo

The cursor will stop at the point in the buffer where the error occurs,
or not long after it. The buffer will look like this:

     ---------- Buffer: *Info Region* ----------
     * Menu:

     * Using texinfo-show-structure:: How to use
                                  'texinfo-show-structure'

```
                                                to catch mistakes.
     * Running Info-Validate::              How to check for
                                            unreferenced nodes.

     @end menus
     -!-
     ---------- Buffer: *Info Region* ----------
```

   The texinfo-format-region command sometimes provides slightly odd
error messages. For example, the following cross reference fails to
format:

     (@xref{Catching Mistakes, for more info.)

In this case, texinfo-format-region detects the missing closing brace
but displays a message that says Unbalanced parentheses rather than
Unbalanced braces. This is because the formatting command looks for
mismatches between braces as if they were parentheses.

   Sometimes texinfo-format-region fails to detect mistakes. For
example, in the following, the closing brace is swapped with the
closing parenthesis:

     (@xref{Catching Mistakes), for more info.}

Formatting produces:
     (*Note for more info.: Catching Mistakes)

   The only way for you to detect this error is to realize that the
reference should have looked like this:

     (*Note Catching Mistakes::, for more info.)

   Incidentally, if you are reading this node in Info and type f RET
(Info-follow-reference), you will generate an error message that
says:

     No such node: "Catching Mistakes) The only way ...

This is because Info perceives the example of the error as the first
cross reference in this node and if you type a RET immediately after
typing the Info f command, Info will attempt to go to the referenced
node. If you type f catch TAB RET, Info will complete the node name of
the correctly written example and take you to the 'Catching Mistakes'
node. (If you try this, you can return from the 'Catching Mistakes'
node by typing l (Info-last).)

1.237 texi.info/Debugging with TeX

                  Catching Errors with TeX Formatting
===================================

   You can also catch mistakes when you format a file with TeX.

   Usually, you do this after you have run texinfo-format-buffer (or,

better, makeinfo-buffer) on the same file, because
texinfo-format-buffer sometimes displays error messages that make
more sense than TeX. (See
                 Debugging with Info
                 , for more information.)

    For example, TeX was run on a Texinfo file, part of which is shown
here:

      ---------- Buffer: texinfo.texi ----------
      name of the texinfo file as an extension. The
      @samp{??} are 'wildcards' that cause the shell to
      substitute all the raw index files. (@xref{sorting
      indices, for more information about sorting
      indices.)@refill
      ---------- Buffer: texinfo.texi ----------

(The cross reference lacks a closing brace.) TeX produced the following
output, after which it stopped:

      ---------- Buffer: *texinfo-tex-shell* ----------
      Runaway argument?
      {sorting indices, for more information about sorting
      indices.) @refill @ETC.
      ! Paragraph ended before @xref was complete.
      <to be read again>
                       @par
      l.27

      ?
      ---------- Buffer: *texinfo-tex-shell* ----------

    In this case, TeX produced an accurate and understandable error
message:

      Paragraph ended before @xref was complete.

 @par is an internal TeX command of no relevance to Texinfo. l.27
means that TeX detected the problem on line 27 of the Texinfo file.
The ? is the prompt TeX uses in this circumstance.

    Unfortunately, TeX is not always so helpful, and sometimes you must
truly be a Sherlock Holmes to discover what went wrong.

    In any case, if you run into a problem like this, you can do one of
three things.

  1. You can tell TeX to continue running and ignore just this error by
     typing RET at the ? prompt.

  2. You can tell TeX to continue running and to ignore all errors as
     best it can by typing r RET at the ? prompt.

     This is often the best thing to do. However, beware: the one error
     may produce a cascade of additional error messages as its
     consequences are felt through the rest of the file. (To stop TeX
     when it is producing such an avalanche of error messages, type C-d

```
     (or C-c C-d, if you are running a shell inside Emacs Version 18.))
```

  3. You can tell TeX to stop this run by typing x RET at the ? prompt.

   Please note that if you are running TeX inside Emacs, you need to
switch to the shell buffer and line at which TeX offers the ? prompt.

   Sometimes TeX will format a file without producing error messages
even though there is a problem. This usually occurs if a command is
not ended but TeX is able to continue processing anyhow. For example,
if you fail to end an itemized list with the @end itemize command, TeX
will write a DVI file that you can print out. The only error message
that TeX will give you is the somewhat mysterious comment that

```
     (@end occurred inside a group at level 1)
```

However, if you print the DVI file, you will find that the text of the
file that follows the itemized list is entirely indented as if it were
part of the last item in the itemized list. The error message is the
way TeX says that it expected to find an @end command somewhere in the
file; but that it could not determine where it was needed.

   Another source of notoriously hard-to-find errors is a missing @end
group command. If you ever are stumped by incomprehensible errors,
look for a missing @end group command first.

   If the Texinfo file lacks header lines, TeX may stop in the
beginning of its run and display output that looks like the following.
The * indicates that TeX is waiting for input.

```
     This is TeX, Version 2.0 for Berkeley UNIX
     (preloaded format=plain-cm 87.10.25)
     (test.texinfo [1])
     *
```

In this case, simply type \end RET after the asterisk. Then write the
header lines in the Texinfo file and run the TeX command again. (Note
the use of the backslash, \ . TeX uses \ instead of @; and in this
circumstance, you are working directly with TeX, not with Texinfo.)

1.238   texi.info/Using texinfo-show-structure

```
Using texinfo-show-structure
============================
```

   It is not always easy to keep track of the nodes, chapters,
sections, and subsections of a Texinfo file. This is especially true
if you are revising or adding to a Texinfo file that someone else has
written.

   In GNU Emacs, in Texinfo mode, the texinfo-show-structure command
lists all the lines that begin with the @-commands that specify the
structure: @chapter, @section, @appendix, and so on. With an

argument (C-u as prefix argument, if interactive), the command also
shows the @node lines. The texinfo-show-structure command is bound to
C-c C-s in Texinfo mode, by default.

   The lines are displayed in a buffer called the *Occur* buffer. For
example, when texinfo-show-structure was run on an earlier version of
this appendix, it produced the following:

        Lines matching "^@\(chapter \|sect\|sub\|unnum\|major\|
        heading \|appendix\)" in buffer texinfo.texi.
          4:@appendix Formatting Mistakes
         52:@appendixsec Catching Errors with Info Formatting
        222:@appendixsec Catching Errors with @TeX{} Formatting
        338:@appendixsec Using @code{texinfo-show-structure}
        407:@appendixsubsec Using @code{occur}
        444:@appendixsec Finding Badly Referenced Nodes
        513:@appendixsubsec Running @code{Info-validate}
        573:@appendixsubsec Splitting a File Manually

   This says that lines 4, 52, and 222 of texinfo.texi begin with the
you move your cursor into the *Occur* window, you can position the
cursor over one of the lines and use the C-c C-c command
(occur-mode-goto-occurrence), to jump to the corresponding spot in
the Texinfo file. See Using Occur, for more information about
occur-mode-goto-occurrence.

   The first line in the *Occur* window describes the regular
expression specified by texinfo-heading-pattern. This regular
expression is the pattern that texinfo-show-structure looks for. See
Using Regular Expressions, for more information.

   When you invoke the texinfo-show-structure command, Emacs will
display the structure of the whole buffer. If you want to see the
structure of just a part of the buffer, of one chapter, for example,
use the C-x n (narrow-to-region) command to mark the region. (See
Narrowing.) This is how the example used above was generated. (To see
the whole buffer again, use C-x w (widen).)

   If you call texinfo-show-structure with a prefix argument by typing
C-u C-c C-s, it will list lines beginning with @node as well as the
lines beginning with the @-sign commands for @chapter, @section, and
the like.

   You can remind yourself of the structure of a Texinfo file by
looking at the list in the *Occur* window; and if you have mis-named a
node or left out a section, you can correct the mistake.

1.239   texi.info/Using occur

Using occur
===========

   Sometimes the texinfo-show-structure command produces too much
information. Perhaps you want to remind yourself of the overall

structure of a Texinfo file, and are overwhelmed by the detailed list
produced by texinfo-show-structure. In this case, you can use the occur
command directly. To do this, type

      M-x occur

and then, when prompted, type a regexp, a regular expression for the
pattern you want to match. (See Regular Expressions.) The occur
command works from the current location of the cursor in the buffer to
the end of the buffer. If you want to run occur on the whole buffer,
place the cursor at the beginning of the buffer.

    For example, to see all the lines that contain the word @chapter in
them, just type @chapter. This will produce a list of the chapters.
It will also list all the sentences with @chapter in the middle of the
line.

    If you want to see only those lines that start with the word
all the lines that end with a word or phrase, end the last word with a
$; for example, catching mistakes$. This can be helpful when you
want to see all the nodes that are part of the same chapter or section
and therefore have the same 'Up' pointer.

    See Using Occur, for more information.

1.240   texi.info/Running Info-Validate

                      Finding Badly Referenced Nodes
================================

    You can use the Info-validate command to check whether any of the
'Next', 'Previous', 'Up' or other node pointers fail to point to a
node. This command checks that every node pointer points to an
existing node. The Info-validate command works only on Info files, not
on Texinfo files.

    The makeinfo program validates pointers automatically, so you do not
need to use the Info-validate command if you are using makeinfo. You
only may need to use Info-validate if you are unable to run makeinfo
and instead must create an Info file using texinfo-format-region or
texinfo-format-buffer, or if you write an Info file from scratch.

                  Using Info-validate
                          How to run Info-validate.

                  Unsplit
                                      How to create an unsplit file.

                  Tagifying
                                    How to tagify a file.

                  Splitting

How to split a file manually.

1.241   texi.info/Using Info-validate

Running Info-validate

   To use Info-validate, visit the Info file you wish to check and type:

     M-x Info-validate

(Note that the Info-validate command requires an upper case 'I'. You
may also need to create a tag table before running Info-validate. See

               Tagifying
               .)

   If your file is valid, you will receive a message that says "File
appears valid". However, if you have a pointer that does not point to
a node, error messages will be displayed in a buffer called *problems in
info file*.

   For example, Info-validate was run on a test file that contained
only the first node of this manual. One of the messages said:

     In node "Overview", invalid Next: Texinfo Mode

This meant that the node called Overview had a 'Next' pointer that did
not point to anything (which was true in this case, since the test file
had only one node in it).

   Now suppose we add a node named Texinfo Mode to our test case but we
do not specify a 'Previous' for this node. Then we will get the
following error message:

     In node "Texinfo Mode", should have Previous: Overview

This is because every 'Next' pointer should be matched by a 'Previous'
(in the node where the 'Next' points) which points back.

   Info-validate also checks that all menu entries and cross references
point to actual nodes.

   Note that Info-validate requires a tag table and does not work with
files that have been split. (The texinfo-format-buffer command
automatically splits large files.) In order to use Info-validate on a
large file, you must run texinfo-format-buffer with an argument so that
it does not split the Info file; and you must create a tag table for
the unsplit file.

1.242   texi.info/Unsplit

```
Creating an Unsplit File
------------------------
```

   You can run Info-validate only on a single Info file that has a tag
table. The command will not work on the indirect subfiles that are
generated when a master file is split. If you have a large file
(longer than 70,000 bytes or so), you need to run the
texinfo-format-buffer or makeinfo-buffer command in such a way that it
does not create indirect subfiles. You will also need to create a tag
table for the Info file. After you have done this, you can run
Info-validate and look for badly referenced nodes.

   The first step is to create an unsplit Info file.

   To prevent texinfo-format-buffer from splitting a Texinfo file into
smaller Info files, give a prefix to the M-x texinfo-format-buffer
command:

```
    C-u M-x texinfo-format-buffer
```

or else

```
    C-u C-c C-e C-b
```

When you do this, Texinfo will not split the file and will not create a
tag table for it.

1.243   texi.info/Tagifying

```
Tagifying a File
----------------
```

   After creating an unsplit Info file, you must create a tag table for
it. Visit the Info file you wish to tagify and type:

```
    M-x Info-tagify
```

(Note the upper case I in Info-tagify.) This creates an Info file with
a tag table that you can validate.

   The third step is to validate the Info file:

```
    M-x Info-validate
```

(Note the upper case I in Info-validate.) In brief, the steps are:

```
    C-u M-x texinfo-format-buffer
    M-x Info-tagify
    M-x Info-validate
```

   After you have validated the node structure, you will be able to

rerun texinfo-format-buffer in the normal way so it will construct a
tag table and split the file automatically, or you can make the tag
table and split the file manually.

1.244 texi.info/Splitting

                Splitting a File Manually

   You should split a large file or else let the texinfo-format-buffer
or makeinfo-buffer command do it for you automatically. (Generally you
will let one of the formatting commands do this job for you. See

                Create an Info File
                .)

   The split-off files are called the indirect subfiles.

   Info files are split to save memory. With smaller files, Emacs does
not have make such a large buffer to hold the information.

   If an Info file has more than 30 nodes, you should also make a tag
table for it. See
                Using Info-validate
                , for information about creating a
tag table. (Again, tag tables are usually created automatically by the
formatting command; you only need to create a tag table yourself if you
are doing the job manually. Most likely, you will do this for a large,
unsplit file on which you have run Info-validate.)

   Visit the Info file you wish to tagify and split and type the two
commands:

     M-x Info-tagify
     M-x Info-split

(Note that the I in Info is upper case.)

   When you use the Info-split command, the buffer is modified into a
(small) Info file which lists the indirect subfiles. This file should
be saved in place of the original visited file. The indirect subfiles
are written in the same directory the original file is in, with names
generated by appending - and a number to the original file name.

   The primary file still functions as an Info file, but it contains
just the tag table and a directory of subfiles.

1.245 texi.info/Refilling Paragraphs

Refilling Paragraphs
****

   The @refill command refills and, optionally, indents the first line
of a paragraph.(1) The @refill command is no longer important, but we
describe it here because you once needed it. You will see it in many
old Texinfo files.

   Without refilling, paragraphs containing long @-constructs may look
bad after formatting because the formatter removes @-commands and
shortens some lines more than others. In the past, neither
texinfo-format-region nor texinfo-format-buffer refilled paragraphs
automatically. The @refill command had to be written at the end of
every paragraph to cause these formatters to fill them. (Both TeX and
makeinfo have always refilled paragraphs automatically.) Now, all the
Info formatters automatically fill and indent those paragraphs that
need to be filled and indented.

   The @refill command causes both the texinfo-format-region command
and the texinfo-format-buffer command to refill a paragraph in the Info
file after all the other processing has been done. For this reason,
you can not use @refill with a paragraph containing either @* or @w{
... } since the refilling action will override those two commands.

   The texinfo-format-region and texinfo-format-buffer commands now
automatically append @refill to the end of each paragraph that should
be filled. They do not append @refill to the ends of paragraphs that
contain @* or @w{ ...} and therefore do not refill or indent them.

           ---------- Footnotes ----------

   (1) Perhaps the command should have been called the
chosen before indenting was possible.

1.246   texi.info/Command Syntax

****

   The character @ is used to start special Texinfo commands. (It has
the same meaning that \ has in PlainTeX.) Texinfo has four types of
1. Non-alphabetic commands.
     These commands consist of an @ followed by a punctuation mark or
     other character that is not part of the alphabet. Non-alphabetic
     commands are almost always part of the text within a paragraph,
     and never take any argument. The two characters (@ and the other
     one) are complete in themselves; none is followed by braces. The
     non-alphabetic commands are: @., @:, @*, @@, , and @}.

2. Alphabetic commands that do not require arguments.
     These commands start with @ followed by a word followed by left-
     and right-hand braces. These commands insert special symbols in
     the document; they do not require arguments. For example,
     @dots{} => ..., @equiv{} => ==, @TeX{} => `TeX', and

```
    @bullet{} => *.
```

3. Alphabetic commands that require arguments within braces.
   These commands start with @ followed by a letter or a word,
   followed by an argument within braces. For example, the command
   @dfn indicates the introductory or defining use of a term; it is
   used as follows: In Texinfo, @@-commands are @dfn{mark-up}
   commands.

4. Alphabetic commands that occupy an entire line.
   These commands occupy an entire line. The line starts with @,
   followed by the name of the command (a word); for example, @center
   or @cindex. If no argument is needed, the word is followed by
   the end of the line. If there is an argument, it is separated from
   the command name by a space. Braces are not used.

   Thus, the alphabetic commands fall into classes that have different
argument syntaxes. You cannot tell to which class a command belongs by
the appearance of its name, but you can tell by the command's meaning:
if the command stands for a glyph, it is in class 2 and does not
require an argument; if it makes sense to use the command together with
other text as part of a paragraph, the command is in class 3 and must
be followed by an argument in braces; otherwise, it is in class 4 and
uses the rest of the line as its argument.

   The purpose of having a different syntax for commands of classes 3
and 4 is to make Texinfo files easier to read, and also to help the GNU
Emacs paragraph and filling commands work properly. There is only one
exception to this rule: the command @refill, which is always used at
the end of a paragraph immediately following the final period or other
punctuation character.   @refill takes no argument and does not require
braces.   @refill never confuses the Emacs paragraph commands because
it cannot appear at the beginning of a line.

1.247   texi.info/Obtaining TeX

How to Obtain TeX
****

   TeX is freely redistributable. You can obtain TeX for Unix systems
from the University of Washington for a distribution fee.

   To order a full distribution, send $200.00 for a 1/2-inch 9-track
1600 bpi (tar or cpio) tape reel, or $210.00 for a 1/4-inch 4-track
QIC-24 (tar or cpio) cartridge, to:

     Northwest Computing Support Center
     DR-10, Thomson Hall 35
     University of Washington
     Seattle, Washington 98195

Please make checks payable to the University of Washington.

   Prepaid orders are preferred but purchase orders are acceptable;

however, purchase orders carry an extra charge of $10.00, to pay for
processing.

   Overseas sites: please add to the base cost $20.00 for shipment via
air parcel post, or $30.00 for shipment via courier.

   Please check with the Northwest Computing Support Center at the
University of Washington for current prices and formats:

      telephone: (206) 543-6259
      email: elisabet@u.washington.edu

1.248   texi.info/New Features

                    Second Edition Features
****

   The second edition of the Texinfo manual describes more than 20 new
Texinfo mode commands and more than 50 previously undocumented Texinfo
edition.

   Here is a brief description of the new commands.

                     New Texinfo Mode Commands
                        The updating commands are especially useful.

                     New Commands
                                  Many newly described @-commands.

1.249   texi.info/New Texinfo Mode Commands

                     New Texinfo Mode Commands
==========================

   Texinfo mode provides commands and features especially designed for
working with Texinfo files. More than 20 new commands have been added,
including commands for automatically creating and updating both nodes
and menus. This is a tedious task when done by hand.

   The keybindings are intended to be somewhat mnemonic.

Update all nodes and menus

   The texinfo-master-menu command is the primary command:

C-c C-u m

```
M-x texinfo-master-menu
     Create or update a master menu.  With C-u as a prefix argument,
     first create or update all nodes and regular menus.

Update Pointers
---------------

Create or update 'Next', 'Previous', and 'Up' node pointers.

See
               Updating Nodes and Menus
               .

C-c C-u C-n
M-x texinfo-update-node
     Update a node.

C-c C-u C-e
M-x texinfo-every-node-update
     Update every node in the buffer.

Update Menus
------------

Create or update menus.

See
               Updating Nodes and Menus
               .

C-c C-u C-m
M-x texinfo-make-menu
     Make or update a menu.

C-c C-u C-a
M-x texinfo-all-menus-update
     Make or update all the menus in a buffer.  With C-u as a prefix
     argument, first update all the nodes.

Insert Title as Description
---------------------------

Insert a node's chapter or section title in the space for the
description in a menu entry line; position point so you can edit the
insert.  (This command works somewhat differently than the other
insertion commands, which insert only a predefined string.)

See
               Inserting Frequently Used Commands
               .

C-c C-c C-d
     Insert title.

Format for Info
---------------
```

Provide keybindings both for the Info formatting commands that are
written in Emacs Lisp and for makeinfo that is written in C.

See

                 Info Formatting
                 .

Use the Emacs lisp texinfo-format... commands:

C-c C-e C-r
     Format the region.

C-c C-e C-b
     Format the buffer.

Use makeinfo:

C-c C-m C-r
     Format the region.

C-c C-m C-b
     Format the buffer.

C-c C-m C-l
     Recenter the makeinfo output buffer.

C-c C-m C-k
     Kill the makeinfo formatting job.

Typeset and Print

Typeset and print Texinfo documents from within Emacs.

See

                 Printing
                 .

C-c C-t C-r
     Run TeX on the region.

C-c C-t C-b
     Run TeX on the buffer.

C-c C-t C-i
     Run texindex.

C-c C-t C-p
     Print the DVI file.

C-c C-t C-q
     Show the print queue.

C-c C-t C-d
     Delete a job from the print queue.

C-c C-t C-k

     Kill the current TeX formatting job.

C-c C-t C-x
     Quit a currently stopped TeX formatting job.

C-c C-t C-l
     Recenter the output buffer.

Other Updating Commands

The "other updating commands" do not have standard keybindings because
they are used less frequently.

See
               Other Updating Commands
               .

M-x texinfo-insert-node-lines
     Insert missing @node lines using section titles as node names.

M-x texinfo-multiple-files-update
     Update a multi-file document. With a numeric prefix, such as C-u
     8, update every pointer and menu in all the files and then
     insert a master menu.

M-x texinfo-indent-menu-description
     Indent descriptions in menus.

M-x texinfo-sequential-node-update
     Insert node pointers in strict sequence.

1.250   texi.info/New Commands

               New Texinfo @-Commands
=======================

   The second edition of the Texinfo manual describes more than 50
commands that were not described in the first edition. A third or so
of these commands existed in Texinfo but were not documented in the
manual; the others are new. Here is a listing, with brief descriptions
of them:

Indexing

Create your own index, and merge indices.

See
               Indices
               .

 @defindex index-name

     Define a new index and its indexing command. See also the
     @defcodeindex command.

 @synindex from-index into-index
     Merge the from-index index into the into-index index. See also
     the @syncodeindex command.

Definitions

Describe functions, variables, macros, commands, user options, special
forms, and other such artifacts in a uniform format.

See

               Definition Commands
                    .

 @deffn category name arguments ...
     Format a description for functions, interactive commands, and
     similar entities.

 @defvr, @defop, ...
     15 other related commands.

Glyphs

Indicate the results of evaluation, expansion, printed output, an error
message, equivalence of expressions, and the location of point.

See

               Glyphs
                    .

 @equiv{}
==
     Equivalence:

 @error{}
error-->
     Error message

 @expansion{}
==>
     Macro expansion

 @point{}
-!-
     Position of point

 @print{}
-|
     Printed output

 @result{}
=>
     Result of an expression

Page Headings

Customize page headings.

See

                 Headings
                   .

 @headings on-off-single-double
      Headings on or off, single, or double-sided.

 @evenfooting [left] @| [center] @| [right]
      Footings for even-numbered (left-hand) pages.

 @evenheading, @everyheading, @oddheading, ...
      Five other related commands.

 @thischapter
      Insert name of chapter and chapter number.

 @thischaptername, @thisfile, @thistitle, @thispage
      Related commands.

Formatting

Format blocks of text.

See

                 Quotations and Examples
                 , and

                 Making Lists and Tables
                   .

 @cartouche
      Draw rounded box surrounding text (not in Info).

 @enumerate optional-arg
      Enumerate a list with letters or numbers.

 @exdent line-of-text
      Remove indentation.

 @flushleft
      Left justify.

 @flushright
      Right justify.

 @format
      Do not narrow nor change font.

 @ftable formatting-command
 @vtable formatting-command

```
     Two-column table with indexing.

 @lisp
     For an example of Lisp code.

 @smallexample
 @smalllisp
     Like @table and @lisp but for @smallbook.
```

Conditionals

Conditionally format text.

See

                @set @clear @value

                 .

```
 @set flag [string]
     Set a flag.  Optionally, set value of flag to string.

 @clear flag
     Clear a flag.

 @value{flag }
     Replace with value to which flag is set.

 @ifset flag
     Format, if flag is set.

 @ifclear flag
     Ignore, if flag is set.
```

Produce unnumbered headings that do not appear in a table of contents.

See

                Structuring

                 .

```
 @heading title
     Unnumbered section-like heading not listed in the table of
     contents of a printed manual.

 @chapheading, @majorheading, @subheading, @subsubheading
     Related commands.
```

Font commands

See

                Smallcaps
                , and

                Fonts
                 .

```
 @r{text }
      Print in roman font.

 @sc{text }
      Print in SMALL CAPS font.
```

Miscellaneous

```
See
                @title @subtitle and @author Commands
                ,
see
                Overfull hboxes
                ,
see
                Footnotes
                ,
see
                Format a Dimension
                ,
see
                Inserting a Minus Sign
                ,
see
                Paragraph Indenting
                ,
see
                Cross Reference Commands
                ,
see
                @title @subtitle and @author
                , and
see
                How to Make Your Own Headings
                .
 @author author
      Typeset author's name.

 @finalout
      Produce cleaner printed output.

 @footnotestyle
      Specify footnote style.

 @dmn{dimension }
      Format a dimension.

 @minus{}
      Generate a minus sign.

 @paragraphindent
      Specify paragraph indentation.

 @ref{node-name, [entry ], [topic-or-title ], [info-file ], [manual ]}
```

Make a reference. In the printed manual, the reference does not
start with the word 'see'.

@title title
    Typeset title in the alternative title page format.

@subtitle subtitle
    Typeset subtitle in the alternative title page format.

@today{}
    Insert the current date.

1.251   texi.info/Command and Variable Index

                Command and Variable Index
****

   This is an alphabetical list of all the @-commands and several
variables. To make the list easier to use, the commands are listed
without their preceding @.

                 * (force line break)
                        Line Breaks

                 . (true end of sentence)
                     Controlling Spacing

                 : (suppress widening)
                        Controlling Spacing

                 @ (single @)
                                Inserting An Atsign

                 { (single {)
                                Inserting Braces

                 } (single })
                                Inserting Braces

                 afourpaper
                                  A4 Paper

                 appendix
                                    unnumbered & appendix

                 appendixsec
                                unnumberedsec appendixsec heading

                 appendixsection
