At Startup...

When MacPing begins to poll a network, it issues an =:=@zone   NBP Lookup request, to find entities which have registered NBP names (such as Responder, RegisterName, BroadCast, etc.)   MacPing then sends a broadcast Echo packet to the network number contained in the first NBP response.   These echo packets find devices which answer Echo packets but have not registered a name.   The resulting list will be sorted by Name.
