feynMF:

Drawing Feynman Diagrams with LATEX and METAFONT

Thorsten Ohl*

Technische Hochschule Darmstadt Schloßgartenstr. 9 D-64289 Darmstadt Germany

March 5, 1995

Abstract

feynMF is a LATEX package for easy drawing of professional quality Feynman diagrams with METAFONT. feynMF lays out most diagrams satisfactorily from the structure of the graph without any need for manual intervention. Nevertheless all the power of METAFONT is available for the most obscure cases.

Copying

feynMF is free software; you can redistribute it and/or modify it under the terms of the GNU General Public License as published by the Free Software Foundation; either version 2, or (at your option) any later version.

feynMF is distributed in the hope that it will be useful, but without any warranty; without even the implied warranty of merchantability or fitness for a particular purpose. See the GNU General Public License for more details.

1 Introduction

1.1 Purpose and scope

In recent years, TeX^1 [1] and LATeX^2 [2] have revolutionized the way we share information in theoretical physics (and other areas). Not only does TeX provide typographical capabilities, which transcend those of commercial "wordprocessors" substantially, TeX documents are also completely portable. Since implementations are available on essentially all computers in use in the community, documents can be shared without the usual restrictions of proprietary data formats. This has enabled us to collaborate on papers with colleagues on the other side of the globe, to replace the mailing of hard copy preprints by electronic transmission and to submit these papers electronically to the publisher.

This portability comes with a price, though. TeX (and LaTeX) do not address the issue of graphical information, apart from the rudimentary (but very useful) capabilities of the LaTeX picture environment and similar packages [3], which provide line drawings like the one in figure 1. As an de facto standard for the inclusion of more complex graphics has emerged the inclusion of PostScript ³ files. The complete document can then be printed on any PostScript device. Still there are areas, where complementary approaches seem worth pursuing. In particular this is the case, if the graphical information is highly formalized, like the case at hand. Feynman diagrams are specified by their topology and the type of particles connecting the vertices. Thus a given diagram can be

¹T_FX is a trademark of the American Mathematical Society.

²IAT_EX might be a trademark of Addison Wesley Publishing Company.

³PostScript is a trademark of Adobe Systems Inc.

reproduced from a very concise specification, if the software is able to choose a reasonable layout (semi-)automatically.

METAFONT⁴ [4] and METAPOST⁵ [5] appear to be the perfect tool for such a purpose, since

- 1. METAFONT is part of any (reasonable) TeX installation, thus available to all potential users,
- 2. both have very powerful graphics primitivs, which allow high quality output, and
- 3. both have builtin linear algebra, which allows us to choose a layout automatically.

Still, providing at least the basic interface in \LaTeX macros seems appropriate for boosting the acceptance among the less technically oriented parts of the audience. Thus \texttt{feynMF}^6 was conceived.

feynMF supports METAFONT as well as METAPOST (under the names feynmp.sty and feynmp.mp).

1.2 Relation to similar packages

Before we start, a couple of words about some complementary packages on the market are in order. First of all: I failed to do my homework and didn't try hard enough to find [6] in a library. I'm sure that in there is a smarter way of returning information from METAFONT to T_EX . Those who don't know the literature are doomed to reinvent the wheel. But this isn't a scholarly work and reinventing the wheel was fun!

1.2.1 Feynman

Micheal Levine's feynman package [7] is implemented on top of the standard LaTeX picture environment [2]. This makes it completely portable (no need for a correct METAFONT installation), but it requires manual layout and the graphics output is (though very useful) less than perfect.

1.2.2 Axodraw

Jos Vermaseren's axodraw package [8] uses \specials to access PostScript primitives for drawing diagrams. This approach is inherently not portable (though the ubiquity of PostScript printers makes this a minor point) but at least as flexible as the present one. It still requires manual layout, though.

1.2.3 Mfpic

Last, but not least, I have to mention Thomas Leathrum's mfpic [9], which was the main inspiration for moving feynMF's user interface from METAFONT to

 $^{^4\}mathsf{METAFONT}$ is a trademark of Addison Wesley Publishing Company.

⁵John Hobby's METAPOST is a modified version of METAFONT which generates (encapsulated) PostScript output. METAPOST can be build trivially on top of the web2c version of TEX and METAFONT for UNIX. Ports to other systems should be simple.

⁶feynMF is not a trademark of anybody.

TEX. It might not have been unreasonable to design and implement feynMF as a package on top of mfpic⁷, But closer inspection shows that feynMF and mfpic are fairly orthogonal. mfpic is ideally suited for handling simple graphical building blocks in formally unconstrained contexts, a task which will be accomplished preferably by direct manual placement of objects. feynMF on the other hand works in the highly formal context of Feynman diagrams (or any other labeled graphs for that matter), which can be draw automatically from a specification.

It will of course be tempting to add more features from mfpic's realm to feynMF in the future, but I will try to be conservative in that respect.

1.3 Historical note

This code has a rather long history⁸. Most of the sections ??, ??, ??, and ?? started in 1989 as feynman.mf, a library of METAFONT macros for drawing Feynman diagrams in my thesis. The layout had to be chossen completely manually, which required a long edit-process-preview cycle and made feynman.mf awkward to use. Nevertheless, it survived for five years without major modifications, only slight enhancements had been made. Early in 1994, I became aware of Thomas Leathrum's mfpic [9]. This inspired me to shift the user interface from METAFONT to LATEX, because this allows a smoother blending of the LATEX picture environment with feynMF. While doing this and after having been taught by Tim Stelzer's and Bill Long's MADGRAPH [10] that minimizing the length of the graph gives surprisingly good results for tree graphs⁹, I added the graph manipulation code in section ??.

And, of course, feynMF is biased towards those kinds of graphs that my students, my colleagues and myself have to draw most often. Comments for improvements from other areas of physics are welcome.

1.4 Projects

1.4.1 Documented METAFONT Interface

In a future version, feynMF will have a more convenient and supported set of macros at the METAFONT level, including more general drawing primitives.

1.4.2 Less Formal Graphs

In addition to the well defined Feynman graphs of perturbation theory there are also less formal and more illustrative graphs in use. For example the "quark diagrams" familiar from papers on hadronic weak decays involve curved lines illustrating the formation of bound states, etc. Future versions of feynMF will provide better support for such graphs, without the need for raw METAFONT coding.

 $^{^7\}mathrm{In}$ fact a change in this direction would be rather easy.

⁸Which is a partial explanation, if not excuse, for its slightly incoherent structure.

⁹I had thought about this earlier myself, but foolishly discarded the idea. I didn't expect such a "too simple" method to give esthetically pleasing results for loop graphs, which were my main concern.

1.4.3 Virtual Graphs

In a future version, feynMF will be able to draw "virtual" graphs, i.e. graphs which are larger than the current limit enforced by numeric overflow at higher resolutions. This can be implemented by calculating the layout of a miniature graph and afterwards distributing the full graph among several METAFONT characters.

1.5 Conclusion

It goes without saying that feynMF is not perfect. There are cases where using a graphical drawing tool with a mouse will give more pleasing results in less time. But in most cases, feynMF will give satisfactory results without any fine tuning. These will be reproducible and independent from the computer it is running on.

2 Usage

2.1 Invocation

Instructing LATEX to use feynMF is as simple as 10

\usepackage{feynmf}

and calling METAFONT should not be harder as

mf '\mode:=localmode; input foobar'

where foobar is the name of your METAFONT output file and localmode is your local printer (e.g. laserjet). The hard part usually lies in instructing TEX and your favorite dvi-driver how to find the generated tfm and gf (resp. pk) files. This is highly system dependent and can be trivial (as in the standard UNIX¹¹ TEX installations) or almost impossible (as under MVS). Please consult your local guide or local "TEX Wizards" on this point.

If you have METAPOST, then you can use it by placing

\usepackage[dvips]{feynmp}

in your LATEX source. Here dvips is an option for the LATEX egraphics package which is used for including the generated PostScript files. It should be replaced by your local supported dvi driver. Calling METAPOST is usually even simpler

mp foobar

¹⁰ As given, this applies to IATEX. But the installation file feynmf209.ins allows to generate special versions feynmf209.sty and feynmp209.sty which are compatible with the obsolete IATEX version 2.09. These files are to be used as documentstyle options.

 $^{^{11}}$ UNIX was a trademark of UNIX Systems Laboratory, but is rumored to have been donored to X/Open.

since there is no mode to be picked.

Please keep in mind that feynMF has been developed for \LaTeX 2ε and the \LaTeX 2.09 compatibility version will always be a retrofitted hack. I will accept bug reports for the 2.09 version, but I urge everybody to move to \LaTeX which is the one and only supported \LaTeX right now.

The flow of information depicted in figure 1 looks much more complicated than it is. The important feature is that there a two sets of files which can be used to distribute a document:

- 1. Iff the recipient has a working METAFONT installation (which shouldn't be a problem, except for some impoverished commercial implementations), the document can be typset from the LATEX source *alone*, by running LATEX, METAFONT and LATEX again (the latter step might have to be repeated to get cross references right).
- 2. Another possibility (which doesn't require METAFONT on the recipient's side), is to distribute the LATEX source, the tfm and gf files (or pk files respectively) along with the label files with extension tn (where n as an integer). Distributing the METAFONT log files is a possible alternative for the latter, but discouraged, because these are prone to be erased accidentally.

I should add one caveat here: some dvi file previewers (e.g. xdvi(1) under UNIX) do not reread font information if the tfm or pk files have changed, even though they reread the dvi file if it has changed. Thus you have to restart such previewers if you have made changes in diagrams to see these changes on the screen.

2.2 Basic usage

The basic features of feynMF are (or rather "should be") available through the LATEX interface. Not knowledge of METAFONT is necessary.

 ${\tt fmffile}$

Upto 255 characters can be placed into one METAFONT file, they are enclosed in a single fmffile environment. The environment takes the filename as argument. Currently feynMF does *not* check that the 255 character limit per file is not overrun.

```
\begin{fmffile}{foobar}
...
\end{fmffile}
```

Note that the filename for the METAFONT file given in the argument of the fmffile environment must not be identical to the LATEX source file name, because the METAFONT .log would be overwritten and LATEX can no longer access the information in this .log file.

fmfchar

Draw one character and place it here. Arguments are $(\langle width \rangle, \langle height \rangle)$ as in:

```
\begin{fmfchar}(40,25)
...
\end{fmfchar}
```

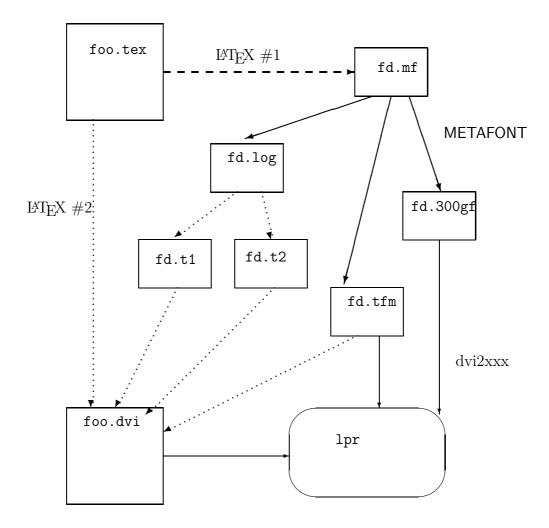

Figure 1: Flow of information in a feynMF application: The first LATEX pass is shown with a dashed line. The METAFONT pass is shown with the full lines and the second LATEX pass with dotted lines. The final dvi translation step is shown with thin lines.

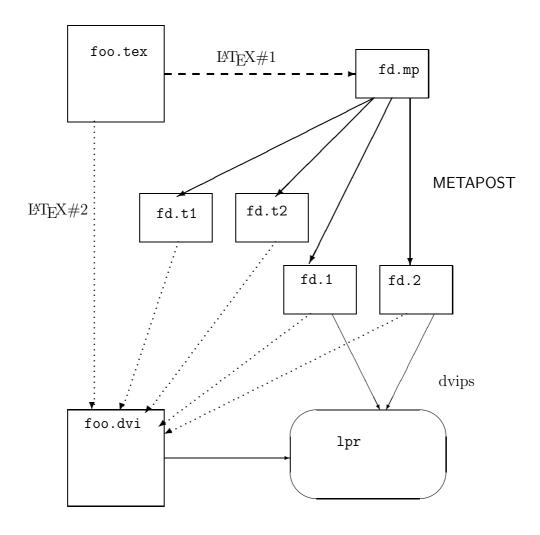

Figure 2: Flow of information in a ${\tt feynMF}$ application if ${\tt METAPOST}$ is used instead of ${\tt METAFONT}.$

This environment does *not* support labels, use fmfchar* if your diagrams contains labels.

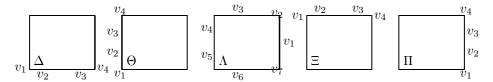

fmfchar*

Same as fmfchar, but enclosed in a picture environment of the same size and supporting LATEX labels.

```
\begin{fmfchar*}(40,25)
...
\end{fmfchar*}
```

\fmfleft
\fmfright
\fmfbottom
\fmftop
\fmfsurround

Positioning of external vertices has to done explicitely. The technical reason is that they would otherwise collapse with their neighbors, but practical reasons also suggest to give the user full control here. $\mathbf{fmfleft}\{\langle v1\rangle[,\ldots]\}$ places the vertices in the comma separated list $\langle v1\rangle[,\ldots]$ does the same thing on the left side of the diagram. $\mathbf{fmfright}\{\langle v1\rangle[,\ldots]\}$ does the same thing on the right. Similarly $\mathbf{fmfbottom}$ and \mathbf{fmftop} , while $\mathbf{fmfsurround}\{\langle v1\rangle[,\ldots]\}$ places its arguments on smooth path surrounding the diagram:

\fmfpen

Pick up a pen of the specified size. $\{\text{meight}\}\$ is used for changing the weight (i.e. thickness) of the lines. Predefined sizes are thin and thick.

\fmf

This is the the most frequently used macro in feynMF applications. $fmf\{\langle style \rangle\}$ $[,\langle opt\rangle [=\langle val\rangle],\ldots]$ $\{\langle v1\rangle,\langle v2\rangle [,\ldots]\}$ connects the vertices $v1,v2,\ldots$ with a line of style $\langle style \rangle$, using a set of options $\langle opt \rangle$ with (optional) value $\langle val \rangle$. If a vertex is not known yet, it is added to the diagram. Note that the actual drawing is not done immediately, because the positions can only be calculated when all vertices are known. The currently available styles are collected in table 1. Most names should be self explanatory and are not discussed further. The dashes, dots, phantom and plain styles can optionally be decorated with an arrow as shown above. All styles, including curly and wiggly, can be doubled. But arrows are not available for the latter two, because esthetically pleasing results can not be expected. The phantom style is special, because it only enters the vertices and does not cause a line to be drawn. This is extremely useful for advanced layout features, as explained below. The supported options are collected in table 2^{12} . Note that each of the dot separated components of the options can be abbreviated. For example, 1.d is equivalent to label.dist. The result of ambiguous matches is however undefined.

 \footnotemark

Declare vertices with options: $\fmfv{\langle shape\rangle[=\langle val\rangle][,\langle opt\rangle[=\langle val\rangle],...]}{\langle v1\rangle}$ [,...]} This is used for adding labels to a vertex and for specifying other decoration. Supported options are collected in table 3. Here the same abbreviation mechanism as above is in effect. The available shapes are listed in various filling styles in table 4^{13} .

\fmfblob

Draw a blob of the specified diameter at the vertices. $fmfblob{\langle diameter \rangle}{\langle v1 \rangle}$

One particulary useful further option would be smooth, allowing for several lines joined smoothly. Early experimentation has shown however, that the results are not always

Name	Examp	ple	Parameters	Aliases

triagram	0	1	2	3
tetragram	4	5	6	7
pentagram	8	9	:	;
hexagram	i	=	į	?

Table 4: Available vertex shapes and fill styles.

[,...]} is equivalent to \fmfv{decor.shape=circle,decor.filled=.5,decor.size= $\langle diameter \rangle$ }{ $\langle v1 \rangle$ [,...]}

\fmfdot Draw a dot at the vertices given as arguments. \fmfdot{ $\langle v1 \rangle$ [,...]} is equivalent to \fmfv{decor.shape=circle,decor.filled=1,decor.size=2thick}{ $\langle v1 \rangle$ [,...]}

\fmfposition Calculate the positions of the vertices based on the arcs which are defined up to this point. Usually this calculation is performed automatically at the end of the fmfchar environment. Calling it explicitly, is useful for adding arcs which should not enter the calculation.

\fmfforce \fmfforce{\langle pos\}{\langle v1\rangle},...]\} forces the position \langle pos\rangle of the vertices \langle v1\rangle..., bypassing the automatic layout.

\fmfshift \fmfforce{\langle dist \rangle} {\langle v1 \rangle \langle \langle v1 \rangle \langle \langle \langle \langle v1 \rangle \langle \

\fmffixed \fmfforce{\langle dist\rangle} {\langle u\rangle},...]} fixes the distance between subsequent vertices in the list $\langle v1 \rangle$... to $\langle dist \rangle$. This command should be used with care, because it is possible to overconstrain the layout of the graph and the error messages will be obscure to a novice user.

2.3 Examples

As an example, consider drawing a straightforward box diagram, familier from $K-\bar{K},\,D-\bar{D},$ and $B-\bar{B}$ mixing. The commands for the labels are not shown here,

what one expects and that there is a lot of room for abuse.

¹³If the variable feymfwizard is true (e.g. after calling the fmfwizard macro), it is also possible to specify any METAFONT expression that evaluates to a path. Naturally, this has to used with great care, because strange errors can be triggered by typos!

they are discussed in section 2.4

We start the diagram and pick up a thick pen:

```
\begin{fmfchar}(40,25)
  \fmfpen{thick}
```

The incoming and outcoming vertices are placed on the left and right hand side, respectively:

Finally we tell feynMF to draw dots at the vertices and we're done.

```
\fmfdot{v1,v2,v3,v4}
\end{fmfchar}
```

Here is the resonant s-channel contribution to $e^+e^- \to 4f$. (From now on, we do no longer display the \begin{fmfchar}(40,25), \fmfpen{thick},..., \end{fmfchar} surrounding all pictures.)

```
\label{eq:continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous_continuous
```

And the resonant t-channel contribution:

Actually, these three diagrams can be improved slightly by using phantom arcs,

which will be discussed in the next section.

Two point loop diagrams pose another set of problems. We must have a way of specifying that one or more of the lines connecting the two vertices are *not* connected by a straight line. The options left, right and straight offer the possibility to connect two vertices by a semicircle detour, either on the left or on the right. Since by default all lines contribute to the tension between two vertices, the tension option allows us to reduce this tension. The next examples shows both options in action. The lower fermion line is given an tension of 1/3 to make is symmetrical with the upper line with consists of three parts. The loop photon is using a detour on the right and does not contribute any tension.

2.4 Labels

Let us now come back to the examples on page 13 and discuss how to add the labels

\fmflabel

The macro $\{ (label) \} \{ \langle v \rangle \}$ adds the label $\langle label \rangle$ to the vertex $\langle v \rangle$. In the current implementation, there can be only a single label for each vertex. Thus earlier calls to $\{ (label) \} \}$ will be overwritten. $\{ (label) \} \}$ will be placed with the $\{ (label) \} \}$ will be placed with the $\{ (label) \} \}$ will be placed with the $\{ (label) \} \}$ with $\{ (label) \} \}$ with

\fmflabel gives the user no control on the placement of the the label (see below for a more fine-grained control provided by the options to the \fmfv macro). The label is placed using the following algorithm:

- 1. The reference point of the box containing $\langle label \rangle$ is placed at the distance **3thick** on the continuation of the straight line connecting the center of the picture with the vertex $\langle v \rangle$.
- 2. The reference point of the box is chosen such that the contents of the box is on the outside of the vertex (with respect to the center of the diagram). It is chosen from the four corners and the four midpoints of the sides.

Therefore the four external particles in the $B\text{-}\bar{B}$ mixing diagram on page 13 are labelled simply by:

```
\fmflabel{$\noexpand\bar b$}{i1}
\fmflabel{$d$}{i2}
\fmflabel{$\noexpand\bar d$}{o1}
\fmflabel{$b$}{o2}
```

Explain more of the label option and the default placement rules.

Advanced usage

2.5.1Shrinking

Shrink the lineswidths and similar parameters in the enclosed section. fmfshrink

2.5.2 Multiple vertices and arcs

```
The macro is\fmfleftn is similar to \fmfleftn, but \fmfleftn\{\langle v\rangle\}\{\langle n\rangle\}
     \fmfleftn
                      places the vertices \langle v[1] \rangle \dots \langle v[n] \rangle. Analogously for the macros \fmfrightn,
    \fmfrightn
                      \fmfbottomn, \fmftopn and \fmfsurroundn.
  \fmfbottomn
      \fmftopn
                      The macro \fmfvn is similar to \fmfv, but \fmfvn{\langle vertex \rangle}{\langle v \rangle}{\langle n \rangle} places
\fmfsurroundn
                     the vertices \langle v[1] \rangle \dots \langle v[n] \rangle.
                      The macros \fmfdotn and \fmfblobn are similar to the \fmfdot and \fmfblob,
          \fmfvn
                      but fmfdotn\{\langle v \rangle\}\{\langle n \rangle\} places the vertices \langle v[1] \rangle ... \langle v[n] \rangle. Analogously for
      \fmfdotn
     \fmfblobn
                      \fmfblobn.
         fmffor
                      The environment \ensuremath{\mbox{begin}\{\mbox{fmffor}\}\{\langle\mbox{var}\rangle\}\{\langle\mbox{tep}\rangle\}\{\langle\mbox{to}\rangle\}\{\langle\mbox{to}\rangle\}\{\langle\mbox{bod}y\rangle\}}
                      executes \langle body \rangle multiple times, setting \langle var \rangle to \langle from \rangle, \langle from \rangle + \langle step \rangle, ..., \langle to \rangle.
                      The macro \{style\}\{\langle v\}\}\{\langle v\}\} cyclically connects the vertices
    \fmfcyclen
  \fmfrcyclen
                      \langle v[1]\rangle \dots \langle v[n]\rangle. \fmfcyclen operates in reverse order.
                      An advanced application of the above feynMF features is shown in figure 3,
                      which is generated by calling the T<sub>E</sub>X macro
                           \def\EulerHeisenberg#1{%
```

```
\begin{fmfchar}(40,25)
 \fmfpen{thick}
 \fmfsurroundn{e}{#1}
 fmf{photon}{e[n],i[n]}
 \end{fmffor}
 \fmfcyclen{fermion,tension=#1/8}{i}{#1}
\end{fmfchar}}
```

with the arguments 4, 6, 8, and 10, respectively.

Similarly, we can draw the diagrams in figures 4 and 4 from many particle physics:

```
\def\PPRing#1{%
  \begin{fmfchar}(20,20)
    \fmfsurroundn{v}{#1}
    \fmfdotn{v}{#1}
    \fmfcyclen{fermion,right=0.25}{v}{#1}
    \fmfcyclen{fermion,left=0.25}{v}{#1}
  \end{fmfchar}}
\def\PHRing#1{%
 \begin{fmfchar}(20,20)
    \fmfsurroundn{v}{#1}
    \fmfdotn{v}{#1}
    \fmfcyclen{fermion,right=0.25}{v}{#1}
    \fmfrcyclen{fermion,right=0.25}{v}{#1}
  \end{fmfchar}}
```

F G

Figure 3: Higher order terms in the Euler-Heisenberg lagrangian.

 $\mathbf{H} \qquad \qquad \mathbf{I} \qquad \qquad \mathbf{J} \qquad \qquad \mathbf{K}$

Figure 4: Particle-particle ring diagrams

2.5.3 Tight arcs

If you add to any arc one or more phantom arcs they will cause a tighter bonding between the vertices involved

```
\fmf{fermion}{v1,v2}
\fmf{phantom}{v1,v2}
```

which is equivalent to

\fmf{fermion,tension=2}{v1,v2}

The phantom arc has to be added *before* any \fmfposition involving these vertices, of course. Here is an example from deep inelastic scattering. (We do not show the \fmfcmd{}s in this example which are used for decorating the

 ${\rm L} \hspace{1cm} {\rm M} \hspace{1cm} {\rm N} \hspace{1cm} {\rm O}$

Figure 5: Particle-hole ring diagrams

incoming proton and do not affect feynMF's layout decisions.)

As it stands, all vertices come out too far to the right, because the greater number of outgoing lines pulls them over. Adding \fmf{phantom} makes the bond between the incoming vertices and the interactions tighter and produces a better balanced picture:

```
\fmfleft{ip,il}
\fmfright{oq1,oq2,d1,oq3,d2,d3,ol}
\fmf{fermion}{ip,vp,vq,oq3}
\fmf{phantom}{ip,vp}
\fmf{fermion}{vp,oq1}
\fmf{fermion}{vp,oq2}
\fmf{photon}{vl,vq}
\fmf{fermion}{il,vl,ol}
\fmf{phantom}{il,vl}
Q
\fmfblob{.15w}{vp}
```

2.5.4 Loose arcs

Adding arcs after any \fmfposition involving these vertices will make these arcs loose, i.e. they will not contribute to the bonding between the vertices. Consider the following example: suppose we want to draw a ladder diagram contributing to the quark form factor. Simply linking in the gluons does not produce a satisfactory result:

```
\fmfleft{i1} \fmfright{o1,o2}
\fmf{photon}{i1,v4}
\fmf{quark}{o1,v1,v2,v3,v4,v5,v6,v7,o2}
\fmf{gluon}{v1,v7}
\fmf{gluon}{v2,v6}
\fmf{gluon}{v3,v5}
```

What went wrong? Obviously the gluons are bonding the quark lines too strongly. The fix is simple: just exclude the gluons from the calculation and add them later as infinitely stretchable:

```
\fmfleft{i1} \fmfright{o1,o2}
\fmf{photon}{i1,v4}
\fmf{quark}{o1,v1,v2,v3,v4,v5,v6,v7,o2}
\fmfposition
\fmf{gluon}{v1,v7}
\fmf{gluon}{v2,v6}
\fmf{gluon}{v3,v5}
```

Another instructive example is the following: imagine you want to draw a typical non-resonant contribution to $e^+e^- \to 4f$. The obvious solution doesn's look right.

```
\fmfleft{i1,i2}
\fmfright{o1,o2,o3,o4}
\fmf{fermion}{i1,v1,i2}
\fmf{photon}{v1,v2}
\fmf{fermion}{o1,v2,v3,o4}
\fmf{photon}{v3,v4}
\fmf{fermion}{o3,v4,o2}
```

One way to fix it is to \fmfshift the three rightmost vertices by hand:

```
\fmfleft{i1,i2}
\fmfright{o1,o2,o3,o4}
\fmf{fermion}{i1,v1,i2}
\fmf{photon}{v1,v2}
\fmf{fermion}{o1,v2,v3,o4}
\fmf{photon}{v3,v4}
\fmf{fermion}{o3,v4,o2}
\fmfposition
\fmfshift{-.1w,0}{v2,v3,v4}
```

A smarter solution is again to make certain arcs stretchable:

```
\fmfleft{i1,i2}
\fmfright{o1,o2,o3,o4}
\fmf{fermion}{i1,v1,i2}
\fmf{photon}{v1,v2}
\fmf{fermion}{o1,v2,v3,o4}
\fmfposition
\fmf{photon}{v3,v4}
\fmf{fermion}{o3,v4,o2}
```

2.5.5 Avoiding continuously tight and loose arcs

I have been very reluctant to implement continuously tight and loose arcs in feynMF, because it introduces to much opportunity for "fiddling" on the user's part. However, since the present implementation blends rather nicely with the options syntax, I have decided to add it anyway. I hope that most diagrams will be created without too much "fiddling".

X

Figure 6: Circular gluons.

2.5.6 Raw METAFONT

Some more advanced features of feynMF are more conveniently accessed through raw METAFONT commands. This can either be achieved by preparing a METAFONT input file or by using \fmfcmd extensively. The latter apprach is usally more convenient.

\fmfcmd

The \fmfcmd macro writes its argument into the METAFONT input file generated by feynMF. While some experience in using METAFONT doesn't hurt here, this approach can simplify the production of complex diagrams considerably. Here's an interesting "abuse" of feynMF. Using the undocumented METAFONT macros (like vdraw_vertex_label) is possible, though not supported. In a future versions, these features will be made available through supported interfaces.

```
\begin{fmfchar*}(40,40)\fmfcmd{
 pair o,xm,xp,ym,yp;
 pair v.loc; string v.lbl;
 o:=(.5w,.1h);
 xm:=(0,.1h); xp:=(w,.1h);
                                                   y = x^2
 ym:=(.5w,0); yp:=(.5w,h);
 v.loc := xp; v.lbl := "$x$";
 v.lbl.ang := -135; v.lbl.dist := 2;
 vdraw_vertex_label v;
 v.loc := yp; v.lbl := "$y=x^2$";
 vdraw_vertex_label v;
 pickup pencircle scaled thin;
 draw xm--xp; draw ym--yp;
 pickup pencircle scaled thick;
 xs:=xpart(xp-o); ys:=ypart(yp-o);
                                                                     x
                                              W
 draw (o + (-xs,ys)) for n = -9 upto 10:
    --(o + (xs*(n/10),ys*((n/10)**2)))
 endfor;}
\end{fmfchar*}
```

Finally, for the curious, here is how to draw the circular gluons in figure 6:

```
\fmfcmd{draw_gluon (fullcircle scaled .5w shifted (.5w,.5h));} \fmfcmd{draw_gluon (reverse fullcircle scaled .5w shifted (.5w,.5h));}
```

2.6 Limitations

Currently the most severe limitation lies in the size of the generated pictures. The largest number METAFONT can represent internally is 4095.99998 and this is also the largest value any coordinate measured in pixels can assume. At the most popular laserprinter resolution of 300 dots per inch (dpi), this corresponds to a horizontal and vertical extension of about 346mm, which is plenty and we're more likely to hit the internal limits on the complexity of a picture. However, at the proof mode resolution of 2601.72dpi, this is reduced to slightly less than 40mm and we're running the risk of arithmetic overflow in internal calculations much earlier.

There are two potential solutions of different scope and complexity:

- Since John Hobby's METAPOST is now available without a non-disclosure agreement from AT&T, one solution is to replace METAFONT by META-POST, which doesn't suffer from the size limitations¹⁴ This comes with a small price paid in reduced portability of the generated output, but as already stated above in the case of axodraw, the ubiquity of PostScript printers (and the free GhostScript interpreter) makes this a minor point.
- The more ambitious solutions will be "virtual pictures" (see section 1.4.3).

Acknowledgements

I am most grateful to Wolfgang Kilian, who pushed feynMF's predecessor feynman.mf to its limits [11]. His needs were valuable input to feynMF. Thanks also to Angelika Himmler and Uwe Mayer for acting as guinea pigs.
