New Technical Notes Macintosh

Polite Use of Borrowed AFP Sessions Networking

M.NW.BorrowedAFP

Written by: Jim Luther

September 1992

This Technical Note shows how to borrow the session reference number of an AFP volume mounted by the Macintosh File System. It also shows how to retrieve other information from the file system for a mounted AFP volume.

Introduction

The AppleShare Chooser extension allows Macintosh applications to perform almost all volume and file access operations on an AppleTalk Filing Protocol (AFP) file server by translating File Manager commands to their AFP equivalent commands. To access a file server, an application normally calls the File Manager. The File Manager calls the AppleShare external file system (part of the AppleShare Chooser extension) which translates the File Manager command into an AFP call. The AppleShare external file system then calls the .XPP driver. The .XPP driver delivers the AFP call to the server and returns the reply to the AppleShare external file system. The AppleShare external file system translates the reply data (if any) and returns it to the File Manager which returns it to the application. Figure 1 shows the normal flow of commands between a Macintosh application and an AFP file server.

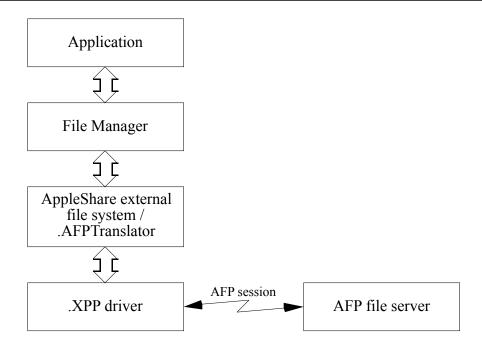

Figure 1 Application Using the File Server Through the File Manager

However, there are a few instances for which no equivalent File Manager commands exist to perform operations supported by AFP. In those instances, an application must use the .XPP driver to access the file server with AFP commands.

Applications accessing a file server with AFP commands need to have an open AFP session with the file server. When no session exists, the application must use the .XPP driver to open an AFP session with the afpLogin (and possibly afpLoginCont) command. However, when an AFP volume on the file server is already mounted by the Macintosh File System, a session is already open with the file server. If the session reference number is retrieved from the .AFPTranslator driver (another part of the AppleShare Chooser extension), that session can be used, *with restrictions*, to access the file server with AFP commands. Figure 2 shows the flow of commands when a Macintosh application accesses an AFP file server directly through the .XPP driver using the session reference number borrowed from the .AFPTranslator driver.

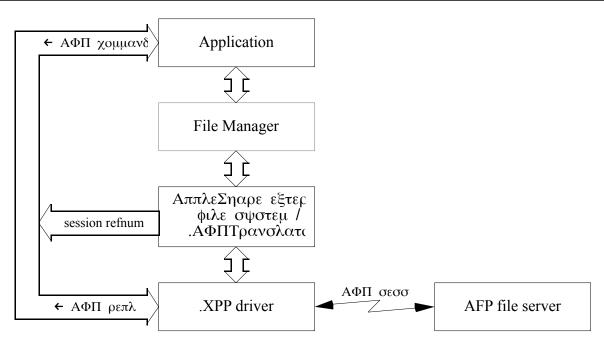

Figure 2 Application Using File Server Through the .XPP Driver with Borrowed Session Reference Number

The next section of this Technical Note tells how to get the AFP session reference number for a mounted AFP volume from the .AFPTranslator driver. It also lists the restrictions you must observe when using the borrowed AFP session.

The Server Volume Information Status Call

The AppleShare external file system performs the translation of File Manager commands to AFP commands and maintains sessions with AFP file servers. The server volume information (AFPSVolInfo) status call to the .AFPTranslator driver can be used to retrieve several important pieces of information stored by the driver. The information returned by the AFPSVolInfo status call is:

- the AFP version used to open the session with the server. This lets you know what possible AFP calls can be made with this session.
- the session reference number. The session reference number is passed to the .XPP driver whenever you make an AFP call.
- the AFP volume ID number. This is the number you pass to AFP calls that require the volume ID number.
- the file server's internet socket address. This is the same internet socket address returned

by the File Manager PBHGetVolParms function in the vMServerAdr field of the GetVolParmsInfoBuffer record.

- the user authentication method (UAM) used to establish the session. This is the same word value returned by the File Manager PBHGetLogInInfo function in ioObjType and by the File Manager PBGetVolMountInfo function in the uamType field of the AFPVolMountInfo record.
- the user name used to establish the session. This is the same string returned by the File Manager PBHGetLogInInfo function in the string pointed to by ioObjNamePtr and by the File Manager PBGetVolMountInfo function as part of the AFPData field in the AFPVolMountInfo record (the exact location of the user name in the AFPData field in the AFPVolMountInfo record is determined by the userNameOffset field).
- the server's volume icon and mask. This is the same 256-byte icon and mask returned by a control call to the disk driver with csCode = 21.
- the string displayed by the Finder's Get Info dialog (after the word "Where:"). This is the same string returned by a control call to the disk driver with csCode = 21.

The information list above is returned in a GetVolSessInfoRec record. The GetVolSessInfoRec record is defined as follows:

```
GetVolSessInfoRec = RECORD
    sessAFPVersion: Integer;
                                    {AFP version number: }
                                       1 = version 1.1 }
                                         2 = \text{version } 2.0 \}
                                         3 = \text{version } 2.1 \}
    sessReferenceNumber: Integer; {session reference number}
    sessAFPVolID: Integer;
                                    {AFP volume identifier}
    sessServerAddress: AddrBlock;
                                    {server internet address}
    sessUAMType: Integer;
                                    {user authentication method: }
                                         1 = 'No User Authent' }
                                         2 = 'Cleartxt Passwrd' }
                                         3 = 'Randnum Exchange' }
                                         6 = '2-Way Randnum exchange' }
    sessUserNamePtr: StringPtr;
                                    {ptr to user name string}
    sessVolIconPtr: Ptr;
                                    {ptr to server volume icon/mask}
    sessWhereStringPtr: StringPtr; {ptr to "where" information string}
  END;
```

Warning: sessUserNamePtr, sessVolIconPtr, and sessWhereStringPtr point to data owned by the .AFPTranslator driver. You must copy that data into your program variables before using it.

The fields in the ParamBlockRec record used for the AFPSVolInfo status call to the .AFPTranslator driver are defined as follows:

\rightarrow	12	ioCompletion	long	pointer to completion routine	
÷	16	ioResult	word	result code	
\rightarrow	24	ioRefNum	word	.AFPTranslator reference number	
Developer Technical Support			REVIEW D	RAFT	September 1992

Macintosh Technical Notes		REVIEW	REVIEW DRAFT	
→	26	a a C a d a	word	
7	26	csCode	word	always AFPSVolInfo
\rightarrow	28	ioMisc	long	pointer to volume's VCB
\rightarrow	32	ioBuffer	long	pointer to GetVolSessInfoRec
\rightarrow	36	ioReqCount	long	size of data requested
÷	40	ioActCount	long	size of data returned

Here are the detailed descriptions of the parameter block fields:

ioCompletion	Longword input pointer: If the AFPSVolInfo status cell is called asynchronously, this must be a pointer to the completion routine or NIL.
ioResult	Word result value: The result code from the function.
ioRefNum	Word input value: The driver reference number of the .AFPTranslator driver.
csCode	Word input value: Always AFPSVolInfo (124).
ioMisc	Longword input pointer: A pointer to the volume's volume control block (VCB).
ioBuffer	Longword input pointer: A pointer to the ${\tt GetVolSessInfoRec}$ where the server volume information is returned.
ioReqCount	Longword input value: The size of the GetVolSessInfoRec pointed to by ioBuffer.
ioActCount	Longword result value: The size of the data returned in the ${\tt GetVolSessInfoRec}$ pointed to by ioBuffer.

The following result codes can be returned by the AFPSVolInfo status call:

noErr	0	No error.	
badUnitErr	-21	The driver reference number is bad.	
unitEmptyErr	-22	The driver reference number is bad.	
notOpenErr	-28	The driver isn't open.	
statusErr	-18	The driver can't respond to this status call.	
paramErr	-50 or the	Either ioReqCount indicates the GetVolSessInfoRec record is too small, the volume specified by ioMisc is not owned by the .AFPTranslator driver.	

The following code shows how to use the AFPSVolInfo status call to get the server volume information for the volume specified by its volume reference number.

```
USES

```
Session Borrowing Rules and Restrictions
```

Warning: The restrictions listed in this Note must be observed when your program borrows an AFP session owned by the Macintosh File System.

There is a good reason why Apple has not documented the AFPSVolInfo status call in the past. AFP file servers differentiate users by their sessions and the AppleShare external file system makes certain assumptions about AFP volumes (and their contents) that it has open. If the session owned by the Macintosh File System is used improperly, you can confuse the AppleShare external file system or the file server. The basic rule you should use when borrowing an AFP session owned by the file system is

If it can be done with File Manager functions, use the File Manager functions—don't use AFP calls.

That means you shouldn't open or close volumes, directories, files, or a volume's desktop database, you shouldn't use calls that require a file or desktop database to be open, and you definitely should not close the AFP session. If you need to do any of those AFP operations, you should use the .XPP driver to open your own AFP session with the file server.

The following is a list of AFP calls that are safe to use with a session borrowed from the file system. For each AFP call, there's an description of what you can do with the call that you cannot do with the File Manager functions.

afpGetSParms	This call can be used to retrieve the server time and the list of server volumes. For each volume, you also can		
	determine if the volume is password-protected and if the volume contains Apple II configuration information.		
afpSetVolParms	This call can be used to set the backup date of a volume.		
afpChangePassword	This call can be used to change the user's password.		
afpGetUserInfo	This call can be used to retrieve the specified user's user ID or primary group ID.		
afpGetSrvrMsg	This call can be used to retrieve the current greeting message or server message. This call is only supported		
	by AFP 2.1 servers. Note: the server message may not be applicable to the user.		
afpMiscUserCommand	reserved for developer use. See Technical Note #323, "Arbitrating Use of afpMiscUserCommand and		
	afpMiscUserWrite."		
afpMiscUserWrite	reserved for developer use. See Technical Note #323, "Arbitrating Use of afpMiscUserCommand and afpMiscUserWrite."		
	wiphilide ober miller		

The list continues. However, these calls should be used only when you need to retrieve or set information (such as ProDOS information) that is inaccessible through File Manager functions.

afpEnumerate	This call can be used to list the contents of a directory when either ProDOS information or specific file o directory attribute information is needed. For all other purposes, the File Manager's PBGetCatInf function should be used.	
afpGetVolParms	This call can be used to retrieve the parameters for a Manager's PBHGetVInfo function should be used in	a particular server volume. For most purposes, the File instead.
afpSetDirParms	· · ·	directory when either ProDOS information or specific other purposes, the File Manager's PBSetCatInfo
afpSetFileParms	1 1	d file when either ProDOS information or specific file poses, the File Manager's PBSetCatInfo function
afpGetFlDrParms		or a specified file or directory when either ProDOS formation is needed. For all other purposes, the File
Developer Technical Support	REVIEW DRAFT	September 1992

Macintosh Technical Notes	REVIEW DRAFT
afpSetFlDrParms	Manager's PBGetCatInfo function should be used. This call can be used to set parameters for a specified file or directory when either ProDOS information or specific file or directory attribute information must be set. For all other purposes, the File Manager's PBSetCatInfo function should be used.
If the AppleShare 3.0 (or later) Cho calls are not supported by the Syste	poser extension is used with System 6, you can make the following AFP 2.1 calls to an AFP 2.1 file server. These m 6 File Manager.
afpGetSrvrMsg afpCreateID afpDeleteID	See description in list above. This call can be used to create a unique file ID for a specified file. This call can be used to invalidate all instances of the specified file ID.
ατρρετείετρ	This can be used to invalidate an instances of the specified life ID.

afpResolveID This call can be used to return information (including the file location) of the specified file ID

afpExchangeFiles This call can be used to exchange the contents of two files on a server volume.

This call can be used to search a volume for files or folders that match specified criteria.

Conclusion

afpCatSearch

The AFPSVolInfo status call to the .AFPTranslator driver returns useful information for developers who need to access an AFP file server in ways not supported by the Macintosh File System. However, the restrictions lists in this note must be observed to prevent problems on the client Macintosh or the AFP file server.
