HST Hubble Space Telescope

Hubble Space Telescope (HST) is an orbiting astronomical observatory operating from the near-infrared into the ultraviolet. Launched in 1990 and scheduled to operate through 2010, HST carries and has carried a wide variety of instruments producing imaging, spectrographic, astrometric, and photometric data through both pointed and parallel observing programs. MAST is the primary archive and distribution center for HST data, distributing science, calibration, and engineering data to HST users and the astronomical community at large. Over 100 000 observations of more than 20 000 targets are available for retrieval from the Archive.

MAST Multimission Archive at Space Telescope

The Multimission Archive at STScI supports a variety of astronomical data archives, with the primary focus on scientifically related data sets in the optical, ultraviolet, and near-infrared parts of the spectrum. MAST provides search tools and retrieval support for the following missions:

Missions				Catalogs & Surveys
HST	ASTRO	ORFEUS	Copernicus	SDSS
FUSE	HUT	BEFS	ROSAT	GSC
IUE	UIT	IMAPS		DSS
EUVE	WUPPE	TUES		VLA-FIRST

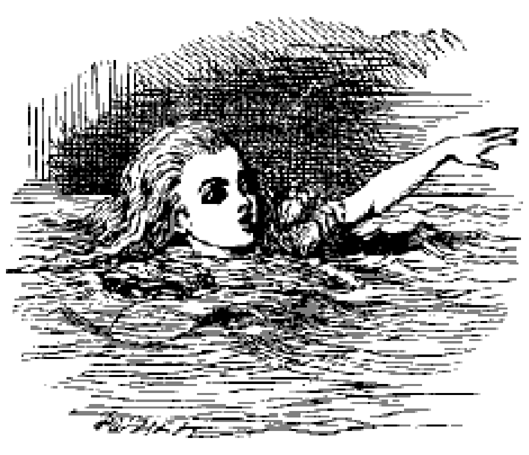
Search Reset Help

MAST Contacts for Help



The Archive Hotseat is available Monday through Friday, 9:00 AM to 5:00 PM Eastern to answer questions about the Archive.

For assistance with the archive, send E-mail to: ***archive@stsci.edu***

For questions about HST data analysis, send E-Mail to: ***help@stsci.edu***

For questions about IUE, Copernicus and EUVE data analysis, send E-Mail to: ***archive@stsci.edu***

E-mail may also be sent to individual ***staff members***.

Cross Mission Searches

Search across missions for single target

List and display representative spectra/images from MAST archive for a single target. (Scrapbook)

Search across missions cross-correlated with catalogs

MAST Index Search Page

Search for: [ ] Submit Options

This page allows users to search for words or phrases in the on-line MAST WEB pages. Enter the desired search string above and either press return or click on "submit". Phrases should be enclosed in double quotes or hyphenated.

If you get too many hits, try:

- entering more keywords,
- changing the proximity control if your keywords should appear together, or
- excluding terms by preceeding them with a minus sign.

If you get too few hits, try fewer keywords, and check your spelling.

About MAST

The **M**ultimission **A**rchive at **ST**ScI supports a variety of astronomical data archives, with the primary focus on scientifically related data sets in the optical, ultraviolet, and near-infrared parts of the spectrum. MAST is a component of NASA's distributed Space Science Data Services (SSDS).

MAST provides a **Cross Correlation Search** tool, enabling users to search all the MAST missions for data with one of the catalogs provided by MAST or a customized catalog provided by the user. Users may also do a "**quick search**" of the MAST holdings for a single object. Search pages for each individual mission are also provided. You may also look at the **Image/Spectral Scrapbook** to see representative images or spectra for a single target.

Preview images/spectra are available for most of the images, allowing users to more easily select the most useful data for their project.

MAST distributes data in a variety of different ways. HST and FUSE data, stored on the DADS optical disk system, are requested and staged either to the users disk or to an anonymous ftp area on this server. (The latter option is available only for non-proprietary data). Other datasets held by MAST are stored on CD in a pair of jukeboxes. Users may select desired data from the search results page and download the data directly to disk via their browsers. Alternatively, some data are available via anonymous ftp on this server.

MAST currently holds or provides links to archival data for the following missions or projects:

- Hubble Space Telescope (HST)
- Far Ultraviolet Spectroscopic Explorer (FUSE)
- International Ultraviolet Explorer (IUE)
- Extreme Ultraviolet Explorer (EUVE)
- ASTRO Missions
  - Hopkins Ultraviolet Telescope (HUT)
  - Ultraviolet Imaging Telescope (UIT)
  - Wisconsin Ultraviolet Photo Polarimetry Experiment (WUPPE)
- Copernicus (OAO-3)
- Orbiting and Retrieval Far and Extreme Ultraviolet Spectrograph (ORFEUS) missions.
  - Berkeley Extreme and Far-UV Spectrometer (BEFS)
  - Interstellar Medium Absorption Profile Spectrograph(IMAPS) (first flight)
  - Tübingen Echelle Spectrograph (TUES)
- Digitized Sky Survey (DSS) & Guide Star Catalog II (GSCII)
- Sloan Digital Sky Survey (SDSS)
- FIRST (VLA radio data)
- Roentgen Satellite (ROSAT)

Although there is no cost involved in retrieving data from MAST, researchers are requested to include an acknowledgement (as shown below) in their publications.

> "Some/all of the data presented in this paper was obtained from the Multimission Archive at the Space Telescope Science Institute (MAST). STScI is operated by the Association of Universities for Research in Astronomy, Inc., under NASA contract NAS5-26555. Support for MAST for non-HST data is provided by the NASA Office of Space Science via grant NAG5-7584 and by other grants and contracts."

Cross-Mission Search Tools

The forms listed below offer a variety of cross-mission search options using either positions extracted from online catalogs, or user-specified target names or positions. Submitting any of the forms will return a table of entries listing the data available from the MAST archive for the target or targets of interest. The "MAST Scrapbook" form will return a table of representative data sets as well as a set of thumbnail images displaying either a plot of the spectrum or the image.

Form	Help	Description
MAST Scrapbook		Lists and displays representative spectra or images from the MAST archive based on user-specified target name or coordinates.
Single Target quick search		Cross-correlation search based on user-specified target name or coordinates.
Hipparcos Catalog		Make cuts on the Hipparcos Catalog and cross-correlate them with MAST's holdings.
SKY2000 Catalog		Query the SKY2000 Catalog (version 3) and cross-correlate results with MAST's holdings.
Active Galactic Nuclei		Make cuts on our catalog of AGN, derived from the Veron-Cetty and Veron (1996) catalog, and cross-correlate them with MAST's holdings.
Abell Galaxy Clusters		Make cuts on the Abell Galaxy Clusters catalog (including the supplementary southern catalog), and cross-correlate them with MAST's holdings.
User-Supplied Catalog		Upload your own list of equatorial sky positions to cross-correlate with MAST's holdings.

MAST Scrapbook

Search the MAST catalog of representative spectra or images for an astronomical object. Enter a target name or coordinates (see help for other options). Only fixed targets (i.e., no solar system objects) are available. A table of results will be displayed along with thumbnails of images or spectra.

What's New for MAST during last 6 months

WUPPE Added to MAST Scrapbook
2002 March 15
Representative spectra from the ASTRO WUPPE mission have been added to the MAST scrapbook available at http://archive.stsci.edu/scrapbook.html

New WUPPE Preview Files
2002 February 28
The WUPPE Preview files have been updated following the format adopted for the other MAST missions. Besides a plot showing flux, polarization, and polarization position angle as a function of wavelength, there are now links to display the FITS header, display the ASCII table file, display/customize a plot of flux versus wavelength, and download data in FITS format. Links to known literature references are also displayed.

More MAST mission data now on-line
2002 February 27
All IUE, UIT, BEFS and VLA-FIRST data are now on-line on a RAID array. The response time for data downloads for these missions should improve significantly. Data for missions HUT, WUPPE, TUES, and Copernicus were already on-line. HST and FUSE data remain on DADS and response times for data download for these two missions are not affected. EUVE data are held at HEASARC and this data is also not affected.

Larger Staging area for HST and FUSE data
2002 February 27
The staging area for HST and FUSE data retrieved with the HOST option has been significantly increased to around 500 GB from 27GB.

Name Resolver Option Available in Cross Correlation search
2002 January 15
The cross correlation search option available from the top MAST page now allows a choice of NED or SIMBAD for resolving user-specified target names. (The previous version only used SIMBAD.)

New MAST/ADS Data Links
2002 January 11
The ADS data links to data archived winthin MAST have been revised. Now a link to a single MAST page is shown which displays all the known MAST references for a single bibcode. (See 1995ApJ...449..488R as an example.)

Coplotting Option now available for IUE Spectra
2001 December 10
A new option is available on the search results page of the IUE search script which allows users to coplot up to 15 selected IUE spectra and interactively rescale the resulting plot.

New Interface for SDSS EDR Quasar Data
2001 December 3
A web-based search and spectra retrieval interface for the SDSS EDR Quasar catalog and spectra, is now available at http://archive.stsci.edu/sdss/quasars/. The interface is based on a generic MAST interface we are developing and comments and suggestions, as always, are welcome at archive@stsci.edu.

Magellanic Cloud Planetary Nebulae Data Sets now Available
2001 November 15
HST prepared datasets of the Magellanic Cloud Planetary Nebulae are now available.

HST Literature Links Update
2001 November 13
The HST reference database table entries (and ADS data links) are now complete through the first half of this year.

EUVE Previews Updated
2001 October 24
Preview files were made available for the last 83 EUVE observations obtained in 2000 and 2001.

New Plotting Option Offered in MAST Scrapbook
2001 October 18
A new option for coplotting multiple spectra and adjusting plot scales is now available in the MAST scrapbook.

Exposure time searches offered for WFPC2 Pointings
2001 September 27
The WFPC2 Pointings search form now allows searches to be performed on total exposure times. See the pointings help page for more information.

OTFR Implemented for NICMOS Data
2001 September 26
As of today, all requests for archived NICMOS data will utilize the On-the-fly Reprocessing (OTFR) system.

Frequently Asked Questions

Data

- ***What type of data are supported by MAST?***
  The Multimission Archive at STScI supports:
  - The Hubble Data Archive (HDA), which contains spectroscopic (1,100 - 11,000 Angstroms range; slitless spectroscopy up to 2.5 microns with NIC3) and imaging (1,150 - 25,000 Angstroms) data taken with Hubble Space Telescope. As of August 1998, the HDA contains over 5.2 Tbytes of science and engineering data, for a total of approximately 150,000 science exposures.
  - The Far Ultraviolet Exporer (FUSE) covers the 905-1187 Å spectral region. This active mission contains high resolution spectra of hot and cool stars, AGNs, supernova remnants, planetary nebulae, solar system objects and the interstellar medium.
  - The International Ultraviolet Explorer (IUE) Final Archive, which contains over 104,000 spectra of approximately 10,000 individual astronomical sources (covering the 1,200 - 3,350 Angstroms range).
  - The Extreme Ultraviolet Explorer (EUVE) Archive, which at present contains spectroscopic observations (in the 70 - 760 Angstroms range) of about 300 sources, mostly Galactic.
  - The Hopkins Ultraviolet Telescope (HUT) Archive, which contains 106 spectrophotometric observations of 77 targets were obtained in the far-UV (i.e., 912-1850 Å) at a resolution of ~3 Å. These were obtained during the first ASTRO mission. An additional 385 observations of 265 targets were obtained during the ASTRO-2 missions.
  - The Ultraviolet Imaging Telescope (UIT) Archive, which contains 1,579 images of 259 targets (covering the 1,200 - 3,300 Å range) obtained by UIT as part of the ASTRO-1 and ASTRO-2 missions.
  - The Wisconsin Ultraviolet Photopolarimeter Experiment (WUPPE) Archive, which contains 467 observations of 169 objects. WUPPE obtained simultaneous spectral and polarization measurements from 1400 to 3300 Å during the ASTRO-1 and ASTRO-2 missions.
  - The Copernicus Archive, which includes far- (900 - 1,560 Angstroms) and near- (1,650 - 3,150 Angstroms) ultraviolet spectra of 551 objects, primarily bright stars.
  - The Berkeley Extreme and Far-UV Spectrometer (BEFS), flew on the Orbiting and Retrievable Far and Extreme Ultraviolet Spectrograph (ORFEUS)-SPAS I and II space shuttle missions in 1993 and 1996, returning high-resolution (/3000) FUV spectra (900-1200 Å) of 75 astrophysical objects from the first flight and more than 100 from the second. EUV spectra (400-900 Å) were obtained for a subset of these targets.
  - The The Interstellar Medium Absorption Profile Spectrograph (IMAPS) obtained high resolution (R=75,000 for IMAPS-1) objective-grating echelle spectra of hot stars, over the spectral region 950-1150 Å. The IMAPS archive currently contains roughly 600 spectral images of 10 hot stars from the first shuttle flight. Once the proprietary period ends for the second IMAPS mission, the archive will include an additional 3,900 spectral images of 29 stars
  - The Tübingen Ultraviolet Echelle Spectrometer (TUES) flew on the Orbiting and Retrievable Far and Extreme Ultraviolet Spectrograph (ORFEUS)-SPAS II space shuttle mission in 1996, returning spectra in the 900 Å to 1400 Å wavelength range. The instrument was designed to achieve a spectral resolution of $\lambda/\Delta\lambda$=10000 when used with an entrance aperture of 10" diameter. During the 17.7 day flight, TUES returned 239 spectra of 62 targets.
  - The Digitized Sky Survey (DSS). The Catalogs and Surveys Branch of the STScI has been digitizing the photographic Sky Survey plates from the Palomar and UK Schmidt telescopes in order to support HST operations and provide a service to the astronomical community. Archive users can easily retrieve image data for any part of the sky.
  - The The Guide Star Catalog I (GSC I) is an all-sky optical catalog of positions and magnitudes of approximately 19 million stars and other objects in the 6th to 15th magnitude range. The GSC II is an all-sky catalog of approximately 2 billion stars and galaxies containing positions, magnitudes, colors and proper motions complete to a minimum of V =18.
  - The Sloan Digital Sky Survey (SDSS) is using a dedicated 2.5 m telescope and a large format CCD camera to obtain images of over 10,000 square degrees of high Galactic latitude sky in five broad bands (u', g', r', i' and z', centered at 3540, 4770, 6230, 7630, and 9130 Å, respectively). The first data release, planned for June 2001, includes: imaging data containing a searchable catalog, images in several formats (FITS and JPEG), and spectra in both FITS format and GIF spectra with line identifications. This first public data release will contain over 500 square degrees of sky.
  - The Faint Images of the Radio Sky at Twenty-centimeters (FIRST) Archive. The FIRST project is designed to produce a radio survey at 20 cm (1.4 GHz) of over 10,000 square degrees down to a flux of 1 mJy. MAST provides access to the radio images and the source catalog, which currently includes about 437,000 entries.
  - The ROSAT, the RÖntgen SATellite, was an X-ray observatory developed through a cooperative program between Germany, the United States, and the United Kingdom. ROSAT data is maintained and archived at HEASARC. Except for the search and acknowledgments pages, all images and linked pages are provided by HEASARC.

- ***How do I search MAST?***
  Every single archive can be searched using its search page. Links to the Web pages of the various archives included in MAST are available from the MAST main page. Moreover, for users wanting to search more than one archive at the same time, two interfaces are provided:
  - From the MAST main page one can conduct a quick search by typing the name of a target to see if any of the MAST supported archives have observations of this target.
  - The MAST Cross Correlation page provides a facility to allow the user to cross-correlate lists of positions with data in our archives. You can compile lists externally or use one of our online catalogs.

- ***How can I retrieve MAST data?***
  All MAST data can be retrieved from the appropriate Web pages. HST, FIRST, and DSS data can also be retrieved using StarView.

Documentation

- ***Are there manuals available for the MAST Archives?***
  Yes. You can get them here:
  - The HDA Manual
  - IUE Reduction/Analysis Documentation
  - IUE Instrumentation/Operations Documentation
  - IUE Project Publications
  - EUVE Project Publications
  - Copernicus Reduction/Analysis Documentation
  - Copernicus Instrumentation and Operations Documentation
  - UIT Publications
  - WUPPE Instrumentation and Operations Documentation
  - HUT Instrumentation and Operations Documentation

- ***Is there a MAST Newsletter?***
  Yes. It is sent out electronically to a distribution list. You can also read it on-line. If you would like to subscribe to the mailing list, please send e-mail to archive_news-request@stsci.edu and put the single word SUBSCRIBE in the BODY of the message.

More FAQ

- ***Can I find FAQ's for individual missions?***
  More FAQ for the single archives are available on the following pages:
  - HDA FAQ Page
  - IUE FAQ Page
  - Copernicus FAQ Page
  - EUVE FAQ Page
  - FUSE FAQ Page
  - BEFS FAQ Page
  - TUES FAQ Page
  - GSC FAQ Page
  - HUT FAQ Page
  - UIT FAQ Page
  - WUPPE FAQ Page
  - DSS FAQ Page

User Support

- ***What level of support is provided for the various missions?***
  Assistance is available for users of the various data included in MAST, although at different levels. Namely:
  - Full support for HST data analysis.
  - Full support for IUE data analysis (except for enhancement of post-pipeline data products).
  - Moderate support for EUVE data analysis.
  - Limited support for DSS, Copernicus, UIT, HUT, and WUPPE data analysis.

  Questions about HST data analysis should be sent to help@stsci.edu.

  Questions about IUE, EUVE, Copernicus, and UIT data analysis should be sent to archive@stsci.edu.

MAST Prepared Science Products

The following is a listing of sites of highly processed datasets from missions supported by MAST. These are datasets consisting of atlases, images, and/or the data themselves which have been placed on the web either as final data products or as appendices referenced in recent published papers. These data are in the public domain and/or will soon be published. The datasets are organized by type of observation (survey, individual objects, time series) and will include a growing number of catalogs with links to the data and in some cases spectra and/or images.

Deep Sky Surveys

- Hubble Deep Field
- Hubble Deep Field South
- Medium Deep Survey

Wide Field Survey Catalogs

- Magellanic Clouds Planetary Nebulae (HST)
- SDSS Quasar Catalog

Spectral Atlases: multi-object samples

- Ultraviolet Spectral Atlas of Standard Stars (IUE)
- Library of Copernicus Atlases of Selected Stars
- Far-Ultraviolet Spectral Atlas of Stars (EUVE)
- Library of IUE NEWSIPS SWP Echelle Spectra for White Dwarfs
- FOS Composite Quasar Spectrum (FOS)

Spectral Atlases: individual objects

- High S/N GHRS LSA G160M Observations of 10 Lacertae (HST)
- High S/N GHRS SSA Echelle Observations of chi Lupi (HST)
- High S/N GHRS SSA Observations of Chromospheric lines in Procyon (HST)
- High S/N GHRS LSA G270M Observations of alpha Ori (HST)

Time-Dependent Spectra

- Grayscale of Time Variations of gamma Cas near SiIV Doublet (HST)

Guidelines for authors of new prepared science products

For further information see: VizieR astronomical catalogs

Data Analysis Software

Some of the data analysis software packages used for the MAST archived data are:

- Space Telescope Science Data Analysis System (STSDAS)
- IUE Data Analysis Center software package (in IDL)
- IRAF/STSDAS tools for IUE data analysis
- EUVE IRAF software package available from STScI
- HUT IRAF data reduction package links

Information on these and other available astronomical data reduction and analysis software packages may be found at the Astronomical Software and Documentation Service.

Flexible Image Transport System (FITS)

The astronomical community has adopted the **Flexible Image Transport System** (i.e. **FITS**) format as the default standard for the exchange of data between institutions. The FITS file format is platform independent, supported by many institutions, and endorsed by both NASA and the IAU. For these reasons FITS is the recommended file format for archiving data at STScI. A description of the MAST data format recommendations can be found in the **MAST Data Format Guidelines** document.

For the official description of the FITS format, see the **FITS Standard Document**.

The **FITS User's Guide** provides examples, infomation on the history of FITS as well as a thorough description of the format.

Acknowledgments

The MAST staff wishes to acknowledge the work that other groups and projects have done and allowed us to use. Thank you to:

- Canadian Astronomy Data Centre (CADC) for the HST preview images
- NASA's Goddard Space Flight Center (GSFC) Astrophysics Data Facility (ADF) staff for access to the IUE and UIT browse images, and copies of the IUE, UIT, WUPPE, and HUT datasets. ADF staff members provided background information and documentation about these datasets. Special thanks to the WISARD group for a copy of their UIT databases.
- GSFC's Laboratory for Astronomy and Solar Physics (LASP) IUE Project for the IUE Documentation, the IUEDAC web pages, the IUEDAC software package, and the initial copy of the database.
- EUVE Project for initial copy of the EUVE database and various web pages.
- WUPPE , UIT , and HUT projects for additional information, documentation, and data.
- High Energy Astrophysics Science Archive Research Center (HEASARC) for access to the on-line copies of the EUVE data
- Dr. George Sonneborn and other members of the GSFC LASP for the Copernicus data, database, and associated web pages.

We would also like to request that users acknowledge the use of data obtained from MAST in their publications. An example acknowledgment is shown below.

> "Some/all of the data presented in this paper were obtained from the Multimission Archive at the Space Telescope Science Institute (MAST). The Far Ultraviolet Spectroscopic Explorer (FUSE), launched on June 24, 1999, covers the 905-1187 Å spectral region and will obtain high resolution spectra of hot and cool stars, AGNs, supernova remnants, planetary nebulae, solar system objects as well as perform detailed studies of the interstellar medium. FUSE will be able to observe sources 10 000 times fainter than Copernicus, an early FUV mission, and has superior resolving power than the Hopkins Ultraviolet Telescope (HUT) and the Berkeley Spectrograph (BEFS) and the Tübingen Echelle Spectrograph (TUES) of the Orbiting Retrievable Far and Extreme Ultraviolet Spectrometers (ORFEUS). FUSE was planned for a 3 year lifetime with funding for an additional 2 years expected.

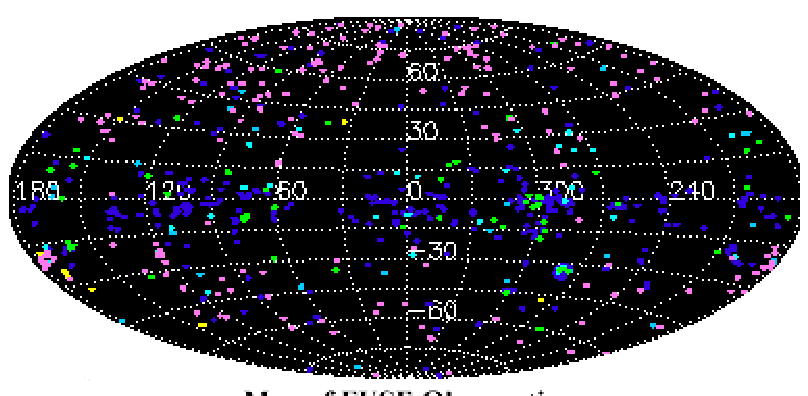
More information about the FUSE Guest Investigator program, including PI and Cycles 1 and 2 GI target lists, may be found at the FUSE Guest Investigator Program site at http://fusewww.gsfc.nasa.gov/.

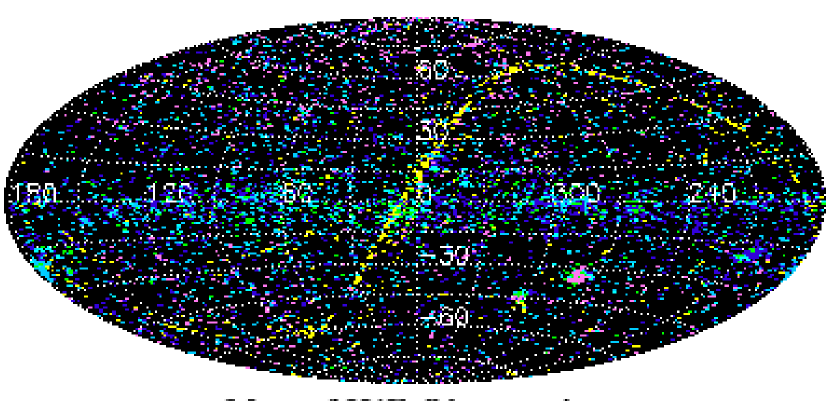
Although FUSE data is maintained and archived within MAST, most of the documentation available from the MAST FUSE page is obtained from the Johns Hopkins FUSE website.



Map of FUSE Observations

IUE International Ultraviolet Explorer

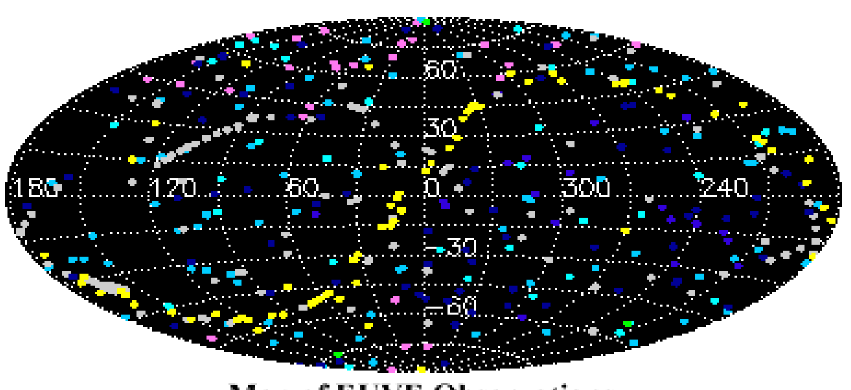
The ***International Ultraviolet Explorer (IUE)*** performed spectrophotometry at high (0.1-0.3 Å) and low (6-7 Å) resolution between 1150 Å and 3200 Å. The data cover a dynamic range of approximately 17 astronomical magnitudes: -2 to 10 for high dispersion; -2 and 14.9 for low dispersion. Over 104,000 ultraviolet spectra were obtained with IUE between January 26, 1978, and September 30, 1996.



Map of IUE Observations

EUVE Extreme Ultraviolet Explorer

Launched in June, 1992, The ***Extreme Ultraviolet Explorer (EUVE)*** conducted the first extreme ultraviolet (70-760 Angstroms) survey of the sky and subsequently began a Guest Observer Program of pointed spectroscopy, that ended on January 31, 2001. The satellite has four photometric imaging systems and a three-channel EUV spectrometer. The imaging instruments were used to complete the sky survey. The spectrometers were used for the pointed spectroscopic programs, which collected data from over 350 unique astronomical targets.



Map of EUVE Observations

Astro

Hopkins Ultraviolet Telescope (HUT)

Ultraviolet Imaging Telescope (UIT)

Wisconsin Ultraviolet Photo-Polarimeter Experiment (WUPPE)

The ***ASTRO Observatory*** had three primary instruments: the Ultraviolet Imaging Telescope (UIT), the Hopkins Ultraviolet Telescope (HUT) and the Wisconsin Ultraviolet Photo-Polarimeter Experiment (WUPPE). The Astro Observatory was designed to use many of the spacelab components and flew on two different shuttle flights. The first Astro flight was on December 2-11, 1990, aboard the shuttle Columbia. The X-ray experiment Broad Band X-Ray Telescope (BBXRT) was also part of the Astro-1 flight. The second flight was on March 2-18, 1995, aboard the shuttle Endeavour.

HUT obtained ultraviolet spectra of astronomical objects such as quasars, active galactic nuclei, and supernova remnants, extending into the little-explored ultraviolet range below 1200 Ångstroms. The instrument consisted of a telescope, prime focus spectrograph, and intensified photodiode array. Scientific studies have included research on the cores of active galaxies (where black holes likely reside), the torus of gas around Jupiter created by its moon Io, the characteristics of the intergalactic medium, and the stellar population in elliptical galaxies.

UIT consisted of a telescope and two image intensifiers with 70 mm film transports. The instrument acquired images of faint objects in broad ultraviolet bands in the wavelength range of 1200 to 3200 Ångstroms. Astronomers have investigated the present stellar content and history of star formation in galaxies, the nature of spiral structure, and non-thermal sources in galaxies using UIT data.

WUPPE obtained both ultraviolet spectra and polarimetry for celestial objects such as hot stars, galactic nuclei, and quasars. The instrument included a telescope, spectropolarimeter, and dual diode array detectors. Researchers have studied the interstellar medium, mass loss from hot stars, interacting binary stars, and active galaxies, among other topics.

HUT Hopkins Ultraviolet Telescope

The ***Hopkins Ultraviolet Telescope HUT*** was one of three ultraviolet instruments of the ASTRO-1 mission flown on the space shuttle Columbia during 2-10 December 1990. 106 spectrophotometric observations of 77 targets were obtained in the far-UV (i.e., 912-1850 Å) at a resolution of ~3 Å. A few sources were observed in the 415-912 Å region with a 1.5 Å resolution. The same three instruments were later flown on the space shuttle Endeavour from 3-17 March 1995 as part of the ASTRO-2 mission. During the longer ASTRO-2 mission, 385 observations of 265 targets were obtained.

The ***Ultraviolet Imaging Telescope UIT*** was one of three ultraviolet telescopes on the ASTRO-1 mission flown on the space shuttle Columbia during 2-10 December 1990. The same three instruments were later flown on the space shuttle Endeavour from 3-17 March 1995, as part of the ASTRO-2 mission. Exposures were obtained on 70-mm photographic film in the 1200-3300 Å range using broadband filters and later digitized using a Perkin-Elmer microdensitometer. Image resolution was 3" over a 40' field of view. Overall, UIT-1 obtained 821 exposures of 66 targets, and UIT-2 obtained 758 images of 193 targets.

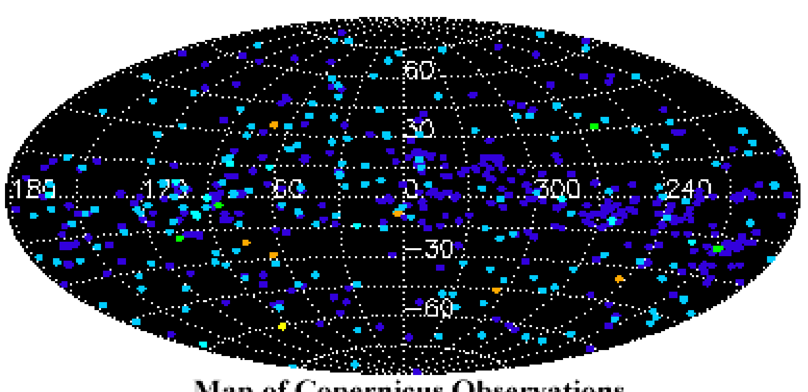
The ***Copernicus*** satellite, otherwise known as the Orbiting Astronomical Observatory 3 (OAO-3), obtained a series of high resolution far- (900-1560 Å) and near- (1650-3150 Å) ultraviolet spectral scans of 551 objects, primarily bright stars, from 1972 to 1981.



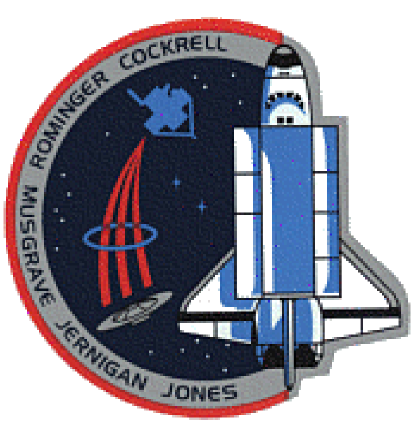
Map of Copernicus Observations

ORFEUS Orbiting Retrievable Far and Extreme Ultraviolet Spectrometers

Interstellar Medium Absorption Profile Spectrograph (IMAPS)

Berkeley Extreme and Far-UV Spectrometer (BEFS)

Tübingen Ultraviolet Echelle Spectrometer (TUES)



The ***Orbiting Retrievable Far and Extreme Ultraviolet Spectrometers (ORFEUS)-SPAS*** payloads were joint DARA (German Space Agency)/NASA missions flown on two shuttle flights. The first flight was September 12-22, 1993 aboard the shuttle Discovery. The second flight, aboard Columbia, was from November 19, through December 7, 1996.

The free-flying ORFEUS-SPAS platform was designed to be deployed and and retrieved from the shuttle.

The three instruments on the ORFEUS were designed to provide astronomical ultraviolet spectroscopic observations over the wavelength range from 40 to 140 nanometers. The three instruments were:

- Tübingen Ultraviolet Echelle Spectrometer (TUES); (PI) Prof. Michael Grewing; University of Tübingen
- Berkeley Extreme and Far-UV Spectrometer (BEFS); (PI) Dr. Mark Hurwitz; University of California, Berkeley. This instrument was called the Extreme Ultraviolet (EUV) Spectrometer in the ORFEUS-SPAS II Mission Research Announcement. It was later renamed.
- Interstellar Medium Absorption Profile Spectrograph (IMAPS); (PI) Dr. Edward Jenkins; Princeton University

The largest science instrument onboard was a 1-meter telescope. The telescope primary was coated with iridium to improve its light gathering power in the ultraviolet. Incoming light was focused to a movable mirror which deflected the light rays into the FUV Spectrometer (i.e., TUES), which operated in the 90-140 nanometer range. When the pick-off mirror was moved out of the beam, light fell instead onto the BEFS Spectrometer, which covered wavelengths between 39 and 120 nanometers. A second, separate instrument, the IMAPS Spectrograph, recorded extremely high resolution spectral data in the 95-115 nanometer range.

This information came from the ORFEUS-SPAS II Mission Research Announcement. A postscript version of this research announcement is located in /archive.stsci.edu/pub/pub/orfeus/orfeus_nra.ps

The **Interstellar Medium Absorption Profile Spectrograph (IMAPS)** obtained high resolution (R=75,000 for IMAPS-1) objective-grating echelle spectra of hot stars, over the spectral region 950-1150 Å. The Principal Investigator was Dr. Edward Jenkins from Princeton University. IMAPS was one of 3 spectrographs comprising the ORFEUS-SPAS mission. The ORFEUS-SPAS platform was deployed from the Space Shuttle Discovery in September, 1993 and from the Space Shuttle Columbia in November, 1996. The IMAPS archive currently contains roughly 600 spectral images of 10 hot stars from the first shuttle flight. Once the proprietary period ends for the second IMAPS mission, the archive will include an additional 3,900 spectral images of 29 stars.

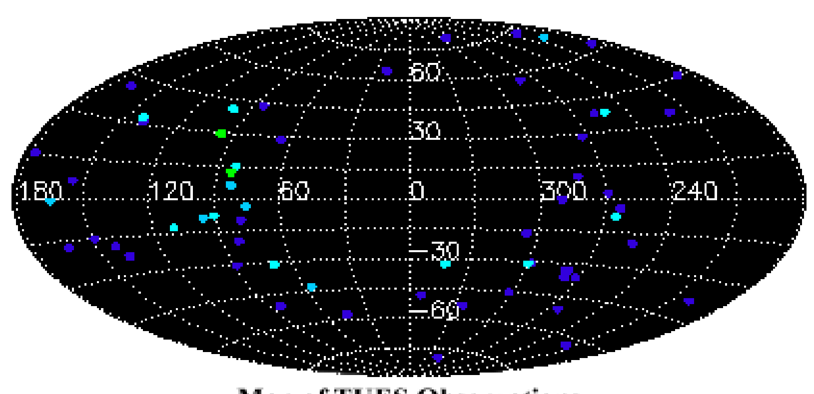
About ORFEUS

Acknowledgments

The ***Tübingen Echelle Spectrograph (TUES)***, designed and managed at the University of Tübingen, flew on the Orbiting and Retrievable Far and Extreme Ultraviolet Spectrograph (ORFEUS)-SPAS II space shuttle mission in 1996, returning spectra in the 900 Å to 1400 Å wavelength range. The instrument was designed to achieve a spectral resolution of $\lambda/\Delta\lambda$=10000 when used with an entrance aperture of 10" diameter. During the 17.7 day flight, TUES returned 239 spectra of 62 targets.



Map of TUES Observations

DSS Digitized Sky Survey

The **Digitized Sky Survey** comprises a set of all-sky photographic surveys in E, V, J, R, and N bands conducted with the Palomar and UK Schmidt telescopes. The Catalogs and Surveys Branch (CASB) is digitizing the photographic plates to support HST observing programs but also as a service to the astronomical community.

The 6.5-degree x 6.5-degree plates are scanned using a modified PDS microdensitometer to a pixel scale of about 1.7 arcseconds per pixel for the POSS, SERC, and Palomar Quick-V surveys, and to about 1.0 arcseconds per pixel for the POSS-II surveys.

Images of any part of the sky may be extracted from the DSS, in either FITS or GIF format.

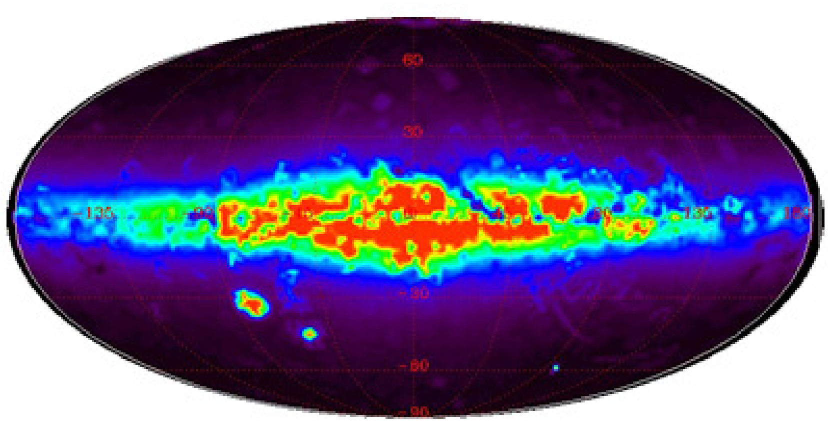
GSC Guide Star Catalogs

The Guide Star Catalogs were created by the staff of the Catalogs and Surveys Branch of the Space Telescope Science Institute.

The **Guide Star Catalog I** (GSC I) is an all-sky optical catalog of positions and magnitudes of approximately 19 million stars and other objects in the 6th to 15th magnitude range. GSC I catalog is used for the control and target acquistion of the Hubble Space Telesope. The **Guide Star Catalog II** (GSC II) is currently in production and will soon be released to the public. The GSC II is an all-sky catalog of approximately 2 billion stars and galaxies containing positions, magnitudes,colors and proper motions complete to a minimum of V =18.

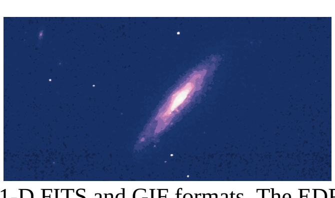
The **Guide Star Photometric Catalog** (GSPC-I) is an all-sky set of photoelectrically determined BV sequences in the magnitude range from 9 to 15, generally near the centers of the fields of the GSC-I plates. GSPC II is currently in production and will soon be released to the public. GSPC II is generally an extension of GSPC I sequences to V=19 in (B), V and R passbands based on CCD photometry. Its purpose is calibration of the GSC-II. New northern sequences are being added to support the POSS-II.

GSC 2.2 now available!.



GSC 2.2 - Galactic Coordinates

Welcome to the Sloan Digital Sky Survey Archive!



The **Sloan Digital Sky Survey** (SDSS) is using a dedicated 2.5 m telescope and a large format CCD camera to obtain images of over 10,000 square degrees of high Galactic latitude sky in five broad bands (u', g', r', i' and z', centered at 3540, 4770, 6230, 7630, and 9130 Å, respectively). Medium resolution spectra will be obtained for approximately 10^6 galaxies and 100,000 quasars. The early data release (EDR), on June 2001, includes searchable catalogs of images and spectra, images for display and scientific purpose in both 2-D FITS and JPEG formats, and spectra in both 1-D FITS and GIF formats. The EDR covers about 460 square degrees of sky. The next data releases will occur every 18 months or so.

Want to hear more? Sign up for one or both of our users' groups for the latest updates. All regular SDSS users must sign up for the Users' Group, or risk missing critical software and documentation updates.

Check the status of the SDSS archive server.

Faint Images of the Radio Sky at Twenty-cm **(FIRST)** is a systematic survey of the North and South Galactic caps begun in 1993, using the **NRAO** Very Large Array **(VLA)** . Typical images are comprised of 1150x1550 1.8" pixels with 5" resolution. Source catalogs are also available including peak and integrated flux densities generated from the high resolution coadded images. The survey yields very accurate (<1 arcsec rms) radio positions of faint (>1 mJy/beam) compact sources. The areas observed were chosen to coincide with the Sloan Digital Sky Survey. For more information, see the **VLA FIRST Web Site**.

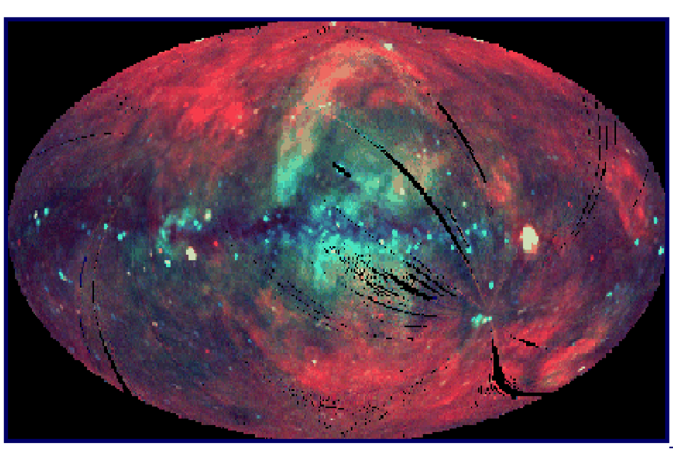
ROSAT,**the RÖntgen SATellite**, was an X-ray observatory developed through a cooperative program between Germany, the United States, and the United Kingdom. The satellite was designed and operated by Germany, and was launched by the United States on June 1, 1990. It was turned off on February 12, 1999. The ROSAT mission began with a 6-month, all sky Position Sensitive Proportional Counter (PSPC) survey, after which the satellite began a series of pointed observations that continued for the duration of the project.

ROSAT data is maintained and archived at HEASARC. Except for the search and acknowledgments pages, all images and linked pages above are provided by HEASARC.



About MAST

The **M**ultimission **A**rchive at **ST**ScI supports a variety of astronomical data archives, with the primary focus on scientifically related data sets in the optical, ultraviolet, and near-infrared parts of the spectrum. MAST is a component of NASA's distributed Space Science Data Services (SSDS).

MAST provides a **Cross Correlation Search** tool, enabling users to search all the MAST missions for data with one of the catalogs provided by MAST or a customized catalog provided by the user. Users may also do a **"quick search"** of the MAST holdings for a single object. Search pages for each individual mission are also provided. You may also look at the **Image/Spectral Scrapbook** to see representative images or spectra for a single target.

Preview images/spectra are available for most of the images, allowing users to more easily select the most useful data for their project.

MAST distributes data in a variety of different ways. HST and FUSE data, stored on the DADS optical disk system, are requested and staged either to the users disk or to an anonymous ftp area on this server. (The latter option is available only for non-proprietary data). Other datasets held by MAST are stored on CD in a pair of jukeboxes. Users may select desired data from the search results page and download the data directly to disk via their browsers. Alternatively, some data are available via anonymous ftp on this server.

MAST currently holds or provides links to archival data for the following missions or projects:

- Hubble Space Telescope (HST)
- Far Ultraviolet Spectroscopic Explorer (FUSE)
- International Ultraviolet Explorer (IUE)
- Extreme Ultraviolet Explorer (EUVE)
- ASTRO Missions
  - Hopkins Ultraviolet Telescope (HUT)
  - Ultraviolet Imaging Telescope (UIT)
  - Wisconsin Ultraviolet Photo Polarimetry Experiment (WUPPE)
- Copernicus (OAO-3)
- Orbiting and Retrieval Far and Extreme Ultraviolet Spectrograph (ORFEUS) missions.
  - Berkeley Extreme and Far-UV Spectrometer (BEFS)
  - Interstellar Medium Absorption Profile Spectrograph(IMAPS) (first flight)
  - Tübingen Echelle Spectrograph (TUES)
- Digitized Sky Survey (DSS) & Guide Star Catalog II (GSCII)
- Sloan Digital Sky Survey (SDSS)
- FIRST (VLA radio data)
- Roentgen Satellite (ROSAT)

Although there is no cost involved in retrieving data from MAST, researchers are requested to include an acknowledgement (as shown below) in their publications.

> "Some/all of the data presented in this paper was obtained from the Multimission Archive at the Space Telescope Science Institute (MAST). STScI is operated by the Association of Universities for Research in Astronomy, Inc., under NASA contract NAS5-26555. Support for MAST for non-HST data is provided by the NASA Office of Space Science via grant NAG5-7584 and by other grants and contracts."

MAST Spectral/Image Scrapbook Help

Help Index:

Please see also:

How we made the scrapbook

Introduction

The MAST Spectral/Image Scrapbook is designed to allow users to take a quick look at sample data in the MAST archive of a particular astronomical object of interest. It is particularly useful if the user is not already familiar with the datasets involved.

The tool utilizes a pair catalogs of representative spectra and images compiled from the MAST archive. Each of the tables lists unique datasets representing either each object or unique pointing observed by each MAST mission/instrument. These datasets contain either a calibrated spectrum or image, as the case may be. More than one dataset may be listed for an assortment of bandpasses, depending on the instrument. For instance, two GHRS spectra are included in the catalog for the star T Tauri, one for the long-wavelength and one for the short-wavelength ultraviolet ranges, among the 13 GHRS spectra in the archive. For IUE, representative images of an object are included for both low and high dispersion if they exist. For WFPC2 images only, one 2.5 x 2.5 arcmin U, B, V, R, and I image is included per pointing when available; a band centered on an emission line is also included when available. In addition, the table lists the names of the object returned by SIMBAD and NED, if available, and the name and coordinates of the object as given in the original observing catalog.

The user may query the table in one of several ways (see Search Criteria listed below):

- Enter an object name to be resolved by SIMBAD or NED, and use the SIMBAD/NED coordinates to search the catalog for any entries within a specified radius of that position.
- Enter a set of coordinates to search the catalog by position.
- Enter an object name to be resolved by SIMBAD or NED, and search the catalog for entries with that resolved name.
- Enter the mission target name to search by object name as catalogued by that mission (may include "%" as a wildcard).

Note that the individual spectra or images in the catalog are typical, not always the best quality available, and are intended to convey the general attributes and quality of the data. To explore further the data available, the user should proceed to the catalog search page for the relevant mission.

For extended objects, some missions obtained data from multiple pointings around the object. In this case for spectra, data from only a single pointing may be displayed (example: the Orion nebula). No attempt has been made to provide a listing of the various pointings for such objects.

Solar system objects are not included in this tool. A special solar system scrapbook tool is under consideration.

Input Parameters

This section describes the options available on the scrapbook search form. Only the target name or position is required; the remaining fields will default to the values shown.

Target
Enter the name or the coordinates of the astronomical object of interest.
- If you specify the name to be resolved for the "Coordinates" or "Resolved Target Name" search, use standard nomenclature as utilized by SIMBAD or NED for best results.
- For the "Mission Target Name" search mode only, a "%" can be used as a wildcard and all names are converted to upper-case; e.g., entering "r136%" will return all entries in which the mission object name begins with R136.
- To specify coordinates, enter J2000 RA and DEC as decimal degrees or as hours, minutes, and seconds. Several formats will be recognized as coordinates:
  - decimal degrees e.g. 65.4975 19.535 or 65.4975, +19.535
  - hours minutes seconds e.g. 4 21 59.4, 19 32 6 or 4 21 59.4 19 32 6
  - hours minutes, deg minutes e.g. 4 21 19 32 or 4 21, 19 32

Data Type
The user specifiies a request for spectral or image data (but not both). By default, spectral data will be displayed.

Search Criteria
Determines how the query of the catalog of representative spectra or images is performed. Three search options are currently available:
- **Coordinates -** Searching the TORS/TORI tables by coordinates within the defined search radius is the default search option. Users may enter their own coordinates (consult examples under "Target"), or use the SIMBAD/NED name resolvers to obtain coordinates. The software uses the resolvers automatically when characters are entered as part of the target name. SIMBAD is the default resolver. As an example, if one enters "NGC4151" for the target, then selects "coordinates" for the search criteria and "SIMBAD" for the name resolver, the scrapbook program uses SIMBAD to determine the coordinates for NGC4151, calculates a circular search area of specified radius centered on the returned coordinates, returns all entries from either Table of Representative Spectra or Images (depending which Data Type is selected) which fall within this area, and displays the spectra or images.
- **Resolved Target Name -** This mode compares the target name returned by SIMBAD or NED to the resolved names stored in the Table of Representative Spectra or Images. This mode is useful when looking for specific targets in crowded fields or for large extended objects, but may also miss some relevant entries. As an example of usage, if one enters "NGC 224", SIMBAD resolves the target as "M 31", and the tool returns entries from the table with the SIMBAD Name "M 31".
- **Mission Target Name -** In this mode the user's input object name is compared directly to the mission object names without using a name resolver. The mission object names are those assigned by the mission and listed in its observing catalog. The names may or may not be consistent with those of other missions. This mode can be useful for targets with unusual designations or to find certain types of objects such as "jets". All input target names are converted to upper-case and a "%" may be used as a wildcard. If one enters "NGC%4151" for example, then entries matching "NGC4151" and "NGC 4151" will be returned. If one enters, "%JET", the entries ending in "JET" such as "HH46-JET" will be returned. This mode is the fastest to execute, but may return only a subset of the desired entries due to differences in the assigned mission object names. Warning: using wildcards can result in extremely large search results.

Search Radius
Enter the coordinate search radius in arcminutes. The default of 3 arcmin will work for many objects, but a smaller radius may be needed in crowded fields. A larger radius may be needed to locate a large extended object. This parameter is not used when searching by name only (see above).

Maximum thumbnails per mission
By default, a maximum of 10 thumbnails will be displayed for each mission. This value may be changed to any number greater than zero. This option affects only the display of the thumbnails. The search results table will always list all the found entries.

Name Resolver
Select either SIMBAD (the default) or NED for name resolution. If the name is not found within either database, try entering coordinates (J2000) instead of a target name. This entry applies only to "Coordinates" and "Resolved Target Name" searches with an input name.

Submit Query
Click on this button to begin the query. The Table of Representative Spectra or Representative Images will be searched for entries which meet the specified search criteria. The result may be none, one, or many objects. You may wish to redo the search with a smaller search radius in a crowded field, or using different search criteria.

Reset
Clicking reset will return the form to its default values.

Help
Clicking help will display this help file. If you still have trouble, please e-mail your question to archive@stsci.edu.

Spectrum Output

The output of your query will include a list of representative data sets for the specified object or coordinates, thumbnails of the spectra or images, and links to browse files, data, and catalog search pages. You may also select spectra to be coplotted using the Customized Plot tool.

Table Headings

Mission/Instrument
The mission and/or instrument from which the data are derived. The table entries will be linked to the appropriate MAST mission home page.

Plot
Click on the appropriate buttons to select the spectra that you would like to display together on one graph (see Customized Plot).

Dataset Name
The name of the dataset in the MAST archive. This may be a single observation or a combination of integrations, depending on the particular mission and instrument involved.

Mission Object Name
The name of the astronomical object as given in the mission catalog. Various

designations were used by the different missions. Since all stored object names are upper case, all input names are converted to upper case when using the "Mission Target Name" mode.

Comments
Explanatory comments regarding the data sets. The contents will vary with mission. Currently the field describes the gratings used by GHRS spectra.

Simbad/NED Name
The name of the astronomical object as returned by SIMBAD (or NED if selected). SIMBAD (NED) is used to resolve multiple designations and to help the user determine if the MAST datasets are of the same target or of multiple targets falling within the search radius. Since some SIMBAD names contain lower case characters, input names are not converted to upper case in "Coordinates" or "Resolved Target Name" modes.

RA (2000), Dec (2000)
The right ascension and declination in J2000 epoch as listed in the Table of Representative Spectra, taken from the mission observing catalog.

Angular Separation
When performing coordinate searches, the angular separation (radius), given in arcminutes, between the SIMBAD (or NED) coordinates and the mission object coordinates listed in the Table of Representative Spectra catalog. The output entries are sorted by mission and angular separation.

Customized Plot

The spectra that you selected will be automatically scaled to the full range of wavelengths and nearly the full range of fluxes (i.e., y axis plot scale runs from 0 (or .25 * the minimum flux for spectra with negative fluxes) to the 10th highest flux). Each spectrum is automatically assigned a color, up to a maximum of 15. The spectra are labelled by their dataset names, with a summary of the datasets plotted given below the plot. After inspecting the plot, you may wish to change the selection of datasets which are displayed. Use your browser "Back" button to do this.

Plot range
Adjust the minimum and maximum wavelengths (in Ångstroms) and minimum and maximum fluxes (in erg/cm^2/sec/Å) to select the spectral region of interest and to exclude noisy data.

Plot dimensions
Adjust the X size and Y size in pixels to create the size of plot desired. The maximum dimensions are 850 by 640 pixels.

Redraw plot
Use this button to replot the spectra when you have changed the plot range or plot dimensions.

Image Output

The output of your query will include a list of representative images for the specified object or coordinates, previews of the images, and links to browse files, data, and catalog search pages.

Table Headings

Mission/Instrument
The mission and/or instrument from which the data are derived. The table entries will be linked to the appropriate MAST mission home page.

Dataset Name
The name of the dataset in the MAST archive. This may be a single observation or a combination of integrations, depending on the particular mission and instrument involved.

Mission Object Name
The name of the astronomical object as given in the mission catalog. Various designations were used by the different missions. Since all stored object names are upper case, all input names are converted to upper case when using the "Mission Target Name" mode.

Comments
Explanatory comments regarding the data sets. The contents will vary with mission. Currently the field describes the filters and apertures used for WFPC2 image data.

Simbad/NED Name
The name of the astronomical object as returned by SIMBAD (or NED if selected). SIMBAD (NED) is used to resolve multiple designations and to help the user determine if the MAST datasets are of the same target or of multiple targets falling within the search radius. Since some SIMBAD names contain lower case characters, input names are not converted to upper case in "Coordinates" or "Resolved Target Name" modes.

RA (2000), Dec (2000)
The right ascension and declination in J2000 epoch as listed in the Table of Representative Images, taken from the mission observing catalog. For WFPC2 images these refer to the position of the V1 axis, i.e., the center of the WFPC2 field of view.

Angular Separation
When performing coordinate searches, the angular separation (radius), given in arcminutes, between the SIMBAD (or NED) coordinates and the mission coordinates listed in the Table of Representative Images catalog. The output entries are sorted by mission and pointing.

Thumbnails and Links

The thumbnails displayed are small but readable quick-look versions of the calibrated data. Descriptions of how these thumbnails were created will be included in the planned mission help pages for the scrapbook.

Click on the mission/instrument name to go to the mission search page to query data from the full mission catalog. The search form will be loaded with the user-specified coordinates (or those derived from NED or SIMBAD) and the user-specified search radius, but the user may modify these or any other search parameter before searching the mission catalog.

For spectra, click on the data_id entry below each thumbnail to view the standard preview page. The preview pages contain a full-sized image of the spectrum and other associated information. Clicking on the mission name above the thumbnail will take the user to a query page filled out with the target name or coordinates and ready to be submitted. This is an alternative way of accessing mission-specific data products for the object. click on the data_id entry or the thumbnail to display a full-size image.

For non-HST missions, click on the object name listed below each thumbnail to download the data (fits files bundled in tar) to your disk. For HST data, click on the object name to display exposure informatiomn.

Click on "Cross Correlation Search" to search the entire MAST archive for a listing of the MAST data sets for a particular target. This will submit the user specified target name to the "xcorr" cross correlation search form. The resolver name, number of entries displayed per mission, and the search radius specified in the scrapbook search form will also be passed to xcorr.

MAST Mission Search Help Page

Overview

This form allows one to

1. perform a quick search by target name or coordinates for a specified set of data types (default is all), or
2. list and briefly describe the available MAST missions for a specified set of data types (default is all).

Clicking the "search" button without any selection criteria will return a list of all the existing MAST data sets. The information below describes the various search options.

Note: if you already know which data set(s) you are interested in, (i.e., which mission or survey), you may instead

- click the "Data Search" link to display a list of links to mission-specific search scripts, or
- click on the mission names shown on the top MAST page to go to the mission home pages (a similiar list is displayed by clicking the "Missions" link at the top of the page).

For further assistance, contact a MAST staff member by clicking the "Contacts" link at the top of the page.

Target Name (or coordinates)
: Entering either a target name to be resolved by SIMBAD (by default) or NED, or J2000 coordinates (RA and DEC separated by a comma) will start a cross-correlation search for appropriate data sets within MAST. If data types are also selected, the search will be restricted to the selected missions.

Data Type(s)
: Archived data sets have been classified according to the type of data (i.e., spectral, image or other) and wavelength coverage. Selecting various data types and wavelength ranges and then clicking "Search", will return a list containing both a summary of each missions data holdings and a link to the mission home pages. If a particular target is also specified, the results page will list the actual data sets available from each of the selected missions.

: The wavelength ranges and data types used in the table are as defined below.

X-ray
: That portion of the electromagnetic spectrum having wavelengths from ~0.1 to ~124 Å (i.e., ~124 kev to ~100 eV).

Extreme UV
: The extreme ultraviolet wavelength range is defined as ~70 to 912 Å.

Far-UV
: The spectral region from 912 to 2000 Å.

Near-UV
: The spectral region from 2000 to 3400 Å.

Optical
: The spectral region from 3400 to ~7500 Å.

Near-IR
: The spectral region from ~7500 Å to ~30 µ.

Radio
: That portion of the electromagnetic spectrum having wavelengths greater than ~10 cm.

Images
: Image data refers to digital images obtained within various bandpasses and with various spatial resolutions. (Note: images of spectra are not included in this category.)

Spectra
: This category refers to spectroscopic data containing calibrated or uncalibrated fluxes as a function of wavelength.

Other
: Data sets listed in the "Other" category include polarimetric, photometric, and astrometric data.

MAST/HIPPARCOS Cross Correlation Help

This page explains how to use the MAST/HIPPARCOS cross-correlator.

You can use this page to cross-correlate subsets of the HIPPARCOS catalog with the HST, IUE, and EUVE archives. To use the form, simply indicate the V magnitude, B-V color, Parallax (mas), and/or Spectral Type that define the subset of the catalog that you're interested in, and which missions you want to cross correlate this subset with. You can optionally specify a search radius for each mission different from the default given in the page.

The MAST cross-correlator will then extract the subset of the HIPPARCOS catalog that meets your qualifications, and will begin polling the selected mission databases to see which missions have observed these stars . The results will be presented in a simple tabular form, with links to the MAST search pages for individual missions:

- The name of the catalog or mission will be linked to that mission's search form, with the RA and Dec for the catalog target as defaults.
- The target name will be linked to a preview image or spectrum, if one is available.
- The name of the exposure (the Dataset Name for HST data, the Entry ID for IUE data, etc) will be linked to a page of information about that specific observation. (This is still under development for non-HST data.)

V Magnitude

Apparent magnitude in the Johnson V band.

```
Qualification  Meaning
-------------- ---------------------------------------
   > 18        V greater (dimmer) than 18
   < 22        V less (brighter) than 22
 18.5 .. 22.5  V between 18.5 and 22.5
   18.0        V of exactly 18
```

The range of values of this field in the HIPPARCOS catalog is -1.44 to 14.08. (This does not mean that the HIPPARCOS catalog is complete to 14.08.)

B-V Color

Johnson B-V color, expressed as a magnitude difference.

Parallax

Trigonometric parallax, in milliarcseconds (mas).

Spectral Type

The spectral type. This field is case-sensitive, so that searches using it will go faster. (The database engine wouldn't be able to use the index otherwise.)

Right ascension range

Right ascension range (J2000). Use this to limit the catalog extraction to a specific area of the sky. This field should be used to specify a *range* of right ascensions. While a single RA would be recognized, in general such a specification would not be useful, since the cross-correlator will try to match the RA *exactly*- an operation that would be subject to the whims of floating-point computer arithmetic.

Here's how to specify a range of right ascensions:

```
12 00 00 .. 14 00 00
12 00 .. 14 00
12h00m00s .. 14h00m00s
12h 00m 00s .. 14h 00m 00s
12h 00' 00" .. 14h 00' 00"
180 .. 210
```

Note that if the right ascension is given as a single floating-point number, as in the last line in the above set of examples, it will be interpreted as degrees, not hours.

You can also use < and >:

```
< 5 00 00
> 14 00 00
< 2, > 20
```

The last line means "less than 2 OR greater than 20". A comma may be to OR two RA qualifications.

Declination range

Declination range (J2000). Use this to limit the catalog extraction to a specific area of the sky. This field should be used to specify a *range* of declinations. While a single Dec would be recognized, in general such a specification would not be useful, since the cross-correlator will try to match the Dec *exactly*- an operation that would be subject to the whims of floating-point computer arithmetic.

Here's how to specify a range of declinations:

```
20 30 00 .. 21 00 00
20 30 .. 21 00
20h30m00s .. 21h00m00s
20h 30m 00s .. 21h 00m 00s
20h 30' 00" .. 21h 00' 00"
20.5 .. 21.0
```

You can also use < and >:

```
< 20
> -20
< -20, > 20
```

The last line means "south of -20 OR north of +20".

Missions

Select one or more missions with which to cross-correlate the selected catalog. (For HST, each instrument is treated as a separate mission.) You can use the **Show catalog entries that match any/all of the selected missions** selector (see below) to control whether any or all missions have to match a catalog entry in order for that catalog entry's results to be displayed.

Radius (arcmin)

The radius in arcminutes on which to cross-correlate the mission with the object catalog catalog. Each mission has its own independent radius. For each mission, a default radius has been chosen that is more or less appropriate for that mission.

Show catalog entries that match any/all of the selected missions

When you select multiple missions, you can use this selector to control how an catalog row's results will be displayed: Set it to `any` to show results if the catalog entry cross-correlates with at least one of the selected missions, or set it to `all` to show only those catalog entries that cross-correlate with *every* selected mission. For example, you might set this selector to `all` if you are looking for catalog entries that have been observed with *both* HST *and* IUE, or to `any` to find catalog entries observed with *either* HST *or* IUE.

Display *n* rows per mission

Use this selector to determine how many rows from each mission will be displayed. When `ALL` is selected, every row found for the mission will be displayed. Optionally, you may use this selector to reduce the number of rows from each mission reported, reducing the length of the results page. The *total number* of rows for each mission will always be reported.

MAST/SKYMAP SKY2000 Version 3 Correlation Help

This page explains how to use the MAST/SKY2000 cross-correlator.

Version 3 of the SKY2000 master catalog contains nearly 300,000 star entries with visual magnitudes between -1.4 and 12.92, all of which have coordinates accurate to less than or equal to 1.5 arcsec. More than 99% of the entries have Johnson V magnitudes, however note that not all the included fields have values for every star entry.

To use the SKY2000 form, simply indicate the V or B magnitude, B-V color, coordinates, Parallax (mas), and/or Spectral Type that define the subset of the catalog that you're interested in, and which missions you want to cross correlate this subset with. The page is initially displayed to search all MAST missions except FGS and HSP. To search on individual missions, first click the "unmark all" button and then select the specific missions desired. (Selecting fewer missions will speed up the search.) You can also specify a search radius for each mission different from the default given in the page.

The MAST cross-correlator will extract the subset of the SKY2000 catalog that meets your qualifications, and will begin polling the selected mission databases to see which missions have observed these stars. (Note that queries returning a large subset of the SKY2000 catalog can take a long time to complete.) The results will be presented in a simple tabular form, with links to the MAST search pages for individual missions:

- The name of the catalog or mission will be linked to that mission's search form, with the RA and Dec for the catalog target as defaults.
- The target name will be linked to a preview image or spectrum, if one is available.
- The name of the exposure (the Dataset Name for HST data, the Entry ID for IUE data, etc) will be linked to a page of information about that specific observation. (This is still under development for non-HST data.)

The MAST project wishes to thank Wayne H. Warren Jr. (Raytheon Technical Services Company) and Christopher B. Sande (Computer Sciences Corporation) for their assistance in obtaining the SKY2000 master catalog and documentation.

V Magnitude
Apparent magnitude in the Johnson V band.

```
Qualification  Meaning
-------------- ---------------------------------------
   > 18        V greater (dimmer) than 18
   < 22        V less (brighter) than 22
 18.5 .. 22.5  V between 18.5 and 22.5
   18.0        V of exactly 18
```

The range of values of this field in the SKY2000 version 3 catalog is -1.44 to 12.92. (This does not mean that the SKY2000 catalog is complete to 12.92.)

B Magnitude
Apparent magnitude in the Johnson B band. The range of values for this field is -1.43 to 16.66.

B-V Color
Johnson B-V color, expressed as a magnitude difference. Values range from -0.6 to 5.9.

Parallax
Trigonometric parallax, in milliarcseconds (mas). Values range from 742 to -343 although negative values have no physical meaning.

Spectral Type
A 30 character field containing spectral class, luminosity class, and peculiarity type. This field is case-sensitive, so that searches using it will go faster. (The database engine wouldn't be able to use the index otherwise.)

Right ascension range
Right ascension range (J2000). Use this to limit the catalog extraction to a specific area of the sky. This field should be used to specify a *range* of right ascensions. While a single RA would be recognized, in general such a specification would not be useful, since the cross-correlator will try to match the RA *exactly*- an operation that would be subject to the whims of floating-point computer arithmetic.

Here's how to specify a range of right ascensions.

```
12 00 00 .. 14 00 00
12 00 .. 14 00
12h00m00s .. 14h00m00s
12h 00m 00s .. 14h 00m 00s
12h 00' 00" .. 14h 00' 00"
180 .. 210
```

Note that if the right ascension is given as a single floating-point number, as in the last line in the above set of examples, it will be interpreted as degrees, not hours.

You can also use < and >:

```
< 5 00 00
> 14 00 00
< 2, > 20
```

The last line means "less than 2 OR greater than 20". A comma may be to OR two RA qualifications.

Declination range
Declination range (J2000). Use this to limit the catalog extraction to a specific area of the sky. This field should be used to specify a *range* of declinations. While a single Dec would be recognized, in general such a specification would not be useful, since the cross-correlator will try to match the Dec *exactly*- an operation that would be subject to the whims of floating-point computer arithmetic.

Here's how to specify a range of declinations:

```
20 30 00 .. 21 00 00
20 30 .. 21 00
20h30m00s .. 21h00m00s
20h 30m 00s .. 21h 00m 00s
20h 30' 00" .. 21h 00' 00"
20.5 .. 21.0
```

You can also use < and >:

```
< 20
> -20
< -20, > 20
```

The last line means "south of -20 OR north of +20".

Missions
Select one or more missions with which to cross-correlate the selected catalog. (For HST, each instrument is treated as a separate mission.) You can use the **Show catalog entries that match any/all of the selected missions** selector (see below) to control whether any or all missions have to match a catalog entry in order for that catalog entry's results to be displayed.

Radius (arcmin)
The radius in arcminutes on which to cross-correlate the mission with the object catalog. Each mission has its own independent radius. For each mission, a default radius has been chosen that is more or less appropriate for that mission.

Show catalog entries that match any/all of the selected missions
When you select multiple missions, you can use this selector to control how an catalog row's results will be displayed: Set it to `any` to show results if the catalog entry cross-correlates with at least one of the selected missions, or set it to `all` to show only those catalog entries that cross-correlate with *every* selected mission. For example, you might set this selector to `all` if you are looking for catalog entries that have been observed with *both* HST *and* IUE, or to `any` to find catalog entries observed with *either* HST *or* IUE.

Display *n* rows per mission
Use this selector to determine how many rows from each mission will be displayed. When ALL is selected, every row found for the mission will be displayed. Optionally, you may use this selector to reduce the number of rows from each mission reported, reducing the length of the results page. The *total number* of rows for each mission will always be reported.

MAST/AGN Cross Correlation Help

This page explains how to use the MAST/AGN cross-correlator. For information on how the AGN catalog was constructed, see the page describing the contents of the AGN catalog.

You can use this page to cross-correlate subsets of our AGN catalog with the HST, IUE, and EUVE archives. To use the form, simply indicate the classes, redshift range, visual magnitude range, and/or 6cm flux range that define the subset of the AGN that you're interested in, and which missions you want to cross correlate this subset with. You can optionally specify a search radius for each mission different from the default given in the page.

The MAST cross-correlator will then extract the subset of the AGN catalog that meets your qualifications, and will begin polling the selected mission databases to see which missions have observed the AGN. The results will be presented in a simple tabular form, with links to the MAST search pages for individual missions:

- The name of the catalog or mission will be linked to that mission's search form, with the RA and Dec for the catalog target as defaults.
- The target name will be linked to a preview image or spectrum, if one is available.
- The name of the exposure (the Dataset Name for HST data, the Entry ID for IUE data, etc) will be linked to a page of information about that specific observation. (This is still under development for non-HST data.)

Object Class

The classification of the AGN. For information on how the AGN were classified, see the section The Classification in the page describing the contents of the AGN catalog.

You may select one or more of these classifications. If you select more than one, then the cut will find AGN that fall into any one of the selected classes. (Each AGN has only one class associated with it.)

Redshift

The redshift of the AGN, expressed as *z*. You can enter a range of floating point numbers here in any of the following ways:

Qualification	Meaning
> 4	*z* greater than 4
< 2	*z* less than 2
2.5 .. 3.5	*z* between 2.5 and 3.5
2.0	*z* of exactly 2

Visual Magnitude

The visual magnitude (*V*) of the AGN. For information on how the visual magnitude was derived, see the page describing the contents of the AGN catalog.

This field can accept a range of floating point numbers:

Qualification	Meaning
> 18	*V* greater (dimmer) than 18
< 22	*V* less (brighter) than 22
18.5 .. 22.5	*V* between 18.5 and 22.5
18.0	*V* of exactly 18

6cm Flux

The radio flux at 6cm, in mJy. For information on how the 6cm flux was derived, see the page describing the contents of the AGN catalog.

This field can accept a range of floating point numbers:

Qualification	Meaning
> 18	flux greater than 18 mJy
< 22	flux less than 22 mJy
18.5 .. 22.5	flux between 18.5 mJy and 22.5 mJy
18.0	flux of exactly 18 mJy

Missions

Select one or more missions with which to cross-correlate the selected catalog. (For HST, each instrument is treated as a separate mission.) You can use the **Show catalog entries that match any/all of the selected missions** selector (see below) to control whether any or all missions have to match a catalog entry in order for that catalog entry's results to be displayed.

Radius (arcmin)

The radius in arcminutes on which to cross-correlate the mission with the object catalog catalog. Each mission has its own independent radius. For each mission, a default radius has been chosen that is more or less appropriate for that mission.

Show catalog entries that match any/all of the selected missions

When you select multiple missions, you can use this selector to control how an catalog row's results will be displayed: Set it to `any` to show results if the catalog entry cross-correlates with at least one of the selected missions, or set it to `all` to show only those catalog entries that cross-correlate with *every* selected mission. For example, you might set this selector to `all` if you are looking for catalog entries that have been observed with *both* HST *and* IUE, or to `any` to find catalog entries observed with *either* HST *or* IUE.

Display *n* rows per mission

Use this selector to determine how many rows from each mission will be displayed. When `ALL` is selected, every row found for the mission will be displayed. Optionally, you may use this selector to reduce the number of rows from each mission reported, reducing the length of the results page. The *total number* of rows for each mission will always be reported.

The AGN Catalog

The Catalog

The Active Galactic Nuclei (AGN) catalog is heavily based on A Catalogue of Quasars and Active Nuclei (7th Edition), ESO Scientific Report No. 17, by Véron-Cetty & Véron (1996) [VV96]. That includes 11,442 quasars and active galaxies, and gives optical magnitudes, redshift, and some radio information. To this we have added: 1. the BL Lac catalog of Padovani & Giommi (1995), updated with BL Lacs discovered in 1996 (for a total of 265 sources); 2. the radio galaxies in the 1 Jy, S4, and S5 radio catalogs, mostly not included in VV96. The resulting database, which totals 12,021 AGN, was also cross-correlated with various radio catalogs providing 6 cm data, namely the PKS database, the PMN survey , the GB6 catalog, the 1 Jy, S4, and S5 radio catalogues. Individual radio fluxes for radio-quiet AGN not included in radio catalogs (radio fluxes < 1 - 30 mJy), taken from the literature, were also added. The V magnitudes in VV96 are actually mostly B or photographic magnitudes when no (B-V) value is available. Therefore, for objects without (B-V) colors, V magnitudes have been derived from the given values by subtracting (B-V) values typical of the class to which an object belongs to, unless the reference was to a paper which gave V magnitudes directly. One should remember that most AGN are variable so the reported V magnitudes should be taken only as indicative. (See Padovani (1997) and Padovani et al. (1997) for some astrophysical applications of an extended version of the catalog.)

The Classification

The classification is based mostly on the one given by VV6, to which the user is referred to, with some differences and additions. Namely:

- AGN UNCLASSIFIED: unclassified sources in Table 3 of VV96 (which includes "active galaxies").
- BL LAC: sources appearing in the BL Lac catalogue of Padovani & Giommi (1995), updated with BL Lacs discovered in 1996.
- LINER: classified as S3 (or Seyfert 3) in VV96.
- QSO: this includes all quasars appearing in Table 1 of VV96, defined by a value of the blue absolute magnitude brighter than -23; for these objects a sub-classification as radio-loud or radio-quiet has been done, based on the two point spectral index alpha_ro (defined here between 5000 Angstroms and 6 cm [5 GHz]). Objects with (K-corrected) alpha_ro > 0.19 (corresponding to the "standard" dividing value of radio flux to optical flux > 10) have been called radio-loud. For the purpose of calculating alpha_ro, V magnitudes have been corrected for extinction following Wilkes et al. (1994) and for the presence of emission lines according to Natali et al. (1998). Radio-loud Seyfert 1 galaxies have been included with the radio-loud QSO, where they belong according to unified schemes for AGN (see, e.g., Urry & Padovani 1995). Note that sometimes radio fluxes are available only at wavelengths other than 6 cm (e.g., from the FIRST or NVSS surveys). In these cases the radio flux at 6 cm used to calculate alpha_ro has been derived by extrapolating the flux assuming a radio spectral index typical of the class to which an object belongs to.
  - QSO (NO V-MAG): 196 QSO without (believe it or not) V magnitude;
  - QSO RADIO-LOUD; QSO (and Seyfert 1 galaxies) with alpha_ro > 0.19 (includes a few QSO without V magnitude but radio flux > 0.5 Jy);
  - QSO RADIO-QUIET; QSO with alpha_ro <= 0.19.
- RADIO GALAXY; from the 1 Jy, S4, and S5; also, radio-loud Seyfert 2 galaxies were checked individually and classified as radio-galaxies if appropriate (radio galaxies are classified as Seyfert 2 galaxies in VV96).
- SEYFERT TYPE 1; sources in Table 3 of VV96 classified as S1 (excluding objects with broad lines in polarized light only); radio-loud Seyfert 1 galaxies are included with the radio-loud QSO (see above).
- SEYFERT TYPE 2; sources in Table 3 of VV96 classified as S2, plus S1 in VV96 with broad lines in polarized light only (classified as S1 in VV96).
- SEYFERT?; sources in Table 3 of VV96 classified as S or S?.
- STARBURST GALAXY; sources in Table 3 of VV96 classified as H2.

Useful Hints

(work in progress)

Disclaimer

Classification of astronomical objects is a complex subject and in many cases the assignement of an object to a given class can be a matter of dispute. We have done our best to be as objective as possible but are obviously open to comments and suggestions about the catalog. These should be sent, along with any questions, to Archive hotseat.

MAST/Abell Clusters Cross Correlation

Abell Clusters Catalog

Redshift (z)

Mag 10

Galactic Latitude

Galactic Longitude

Richness
0
1
2
3
4
5

Note Since a cluster can cover a relatively large area of the sky, the search radius for Abell Clusters will be the aperture radius *plus the radius of the cluster*. The cluster radius, in arcminutes, is calculated from the redshift; see the help file.

MAST/Abell Clusters Cross Correlation Help

This page explains how to use the MAST/Abell Clusters cross-correlator.

You can use this page to cross-correlate subsets of the Abell Clusters catalog with the currently archived MAST missions. To use the form, simply indicate the redshift range, visual magnitude range (see below), richness class(es), and/or a range of galactic coordinates that define the subset of the clusters that you're interested in, and which missions you want to cross correlate this subset with. You can optionally specify a search radius for each mission different from the default given in the page.

The MAST cross-correlator will then extract the subset of the Abell Clusters catalog that meets your qualifications, and will begin polling the selected mission databases to see which missions have observed the clusters. The results will be presented in a simple tabular form, with links to the MAST search pages for individual missions:

- The name of the catalog or mission will be linked to that mission's search form, with the RA and Dec for the catalog target as defaults.
- The target name will be linked to a preview image or spectrum, if one is available.
- The name of the exposure (the Dataset Name for HST data, the Entry ID for IUE data, etc) will be linked to a page of information about that specific observation. (This is still under development for non-HST data.)

A note about the search radius: Abell clusters can be large, so a search radius on the order of the instrument aperture may be too small. We have therefore defined radii for all of the clusters for which we have a valid redshift. The search radius will be the cluster radius (in arcminutes) *plus* the aperture radius for the instrument. (Clusters for which a radius has not been defined- because a redshift was not available- will be searched on the aperture radius alone.)

Richness Class

The richness class of the cluster.

You may select one or more richness class. If you select more than one, then the cross-correlator will find clusters that fall into any one of the selected classes.

Redshift

The redshift of the cluster, expressed as z. You can enter a range of floating point numbers here in any of the following ways:

Qualification	Meaning
> .75	*z* greater than .75
< .3	*z* less than .3
.3 .. .75	*z* between .3 and .75
.3	*z* of exactly .3

Mag 10

The visual magnitude (*V*) of the 10th-brightest galaxy in the cluster. This field can accept a range of floating point numbers:

Qualification	Meaning
> 18	*V* greater (dimmer) than 18
< 22	*V* less (brighter) than 22
18.5 .. 22.5	*V* between 18.5 and 22.5
18.0	*V* of exactly 18

Galactic Longitude Range

Galactic longitude range (*lii*). Use this field to restrict the catalog to a range of galactic longitudes.

This field can accept a range of floating point numbers:

Qualification	Meaning
> 270	*lii* greater than 270 degrees
< 30	*lii* less than 30 degrees
160 .. 200	*lii* between 160 and 200 degrees
< 30, > 270	*lii* between 270 and 30 degrees (including 0 degrees)

If you enter a single floating-point number, the cross-correlator will try to match that number exactly, so this probably isn't a useful way to qualify this field.

Galactic Latitude Range

Galactic latitude range (*bii*). Use this field to restrict the catalog to a range of galactic latitudes.

This field can accept a range of floating point numbers:

Qualification	Meaning
> 60	*bii* greater than 60 degrees
< -60	*bii* less than -60 degrees
-30 .. 30	*bii* between -30 and +30 degrees
< -60, > 60	*bii* less than -60 or greater than +60 degrees

If you enter a single floating-point number, the cross-correlator will try to match that number exactly, so this probably isn't a useful way to qualify this field.

Missions

Select one or more missions with which to cross-correlate the selected catalog. (For HST, each instrument is treated as a separate mission.) You can use the **Show catalog entries that match any/all of the selected missions** selector (see below) to control whether any or all missions have to match a catalog entry in order for that catalog entry's results to be displayed.

Radius (arcmin)

The radius in arcminutes on which to cross-correlate the mission with the object catalog catalog. Each mission has its own independent radius. For each mission, a default radius has been chosen that is more or less appropriate for that mission.

Show catalog entries that match any/all of the selected missions

When you select multiple missions, you can use this selector to control how an catalog row's results will be displayed: Set it to `any` to show results if the catalog entry cross-correlates with at least one of the selected missions, or set it to `all` to show only those catalog entries that cross-correlate with *every* selected mission. For example, you might set this selector to `all` if you are looking for catalog entries that have been observed with *both* HST *and* IUE, or to `any` to find catalog entries observed with *either* HST *or* IUE.

Display *n* rows per mission

Use this selector to determine how many rows from each mission will be displayed. When `ALL` is selected, every row found for the mission will be displayed. Optionally, you may use this selector to reduce the number of rows from each mission reported, reducing the length of the results page. The *total number* of rows for each mission will always be reported.

MAST Cross Correlation Help

This page explains how to use the MAST cross-correlator.

You can use this page to cross-correlate a list of sky positions with the HST, IUE, and EUVE archives. To use the form, you will need a file containing the list of sky positions you want to use as an input catalog. The format of this file is discussed below. Also, select which missions you want to cross correlate this input catalog with. You can optionally specify a search radius for each mission different form the default given in the page.

The MAST cross-correlator will then parse your input catalog and begin polling the selected mission databases to see which missions have observations at your catalog potisions. The results will be presented in a simple tabular form, with links to the MAST search pages for individual missions.

Format of the Input File

The input file should have one entry per row; blank lines and lines beginning with a # character will be ignored. Each row should contain columns delimited by one of the column-delimiting characters shown in the Column Delimiter popup menu in the form. (currently, these are tab, comma, pipe, semicolon, and colon). The RA and Dec can appear in any column. (Currently, the coordinates will be assumed to be equatorial with an equinox of J2000.)

Here are some examples of input-file formats:

- Comma-delimited file, RA in column 1, Dec in column 2:

```
240.083157,-22.621305,HD143275
261.347982,-56.377399,HD157246
67.278648,-13.048497,HD28497
24.426019,-57.236367,HD10144
```

- Pipe-delimited file, RA in column 2, Dec in column 3:

```
HD143275 | 16:00:19 | -22:37:16
HD157246 | 17:25:23 | -56:22:38
HD28497  | 04:29:06 | -13:02:54
HD10144  | 01:37:42 | -57:14:10
```

- Tab-delimited file, RA in column 1, Dec in column 2, with a comment line (which will be skipped):

```
# RA              Dec
16 00 19        -22 37 16
17 25 23        -56 22 38
04 29 06        -13 02 54
01 37 42        -57 14 10
```

Make sure that each column is separated by only one delimiter.

Once you have your input file, in the cross-correlation form, indicate the name of the file on your system, the character which delimits the columns (see below), and the column numbers of the RA and Dec (see below). Then hit the **Submit Query** button. Your browser will then send the contents of your input file to our server, which will search the Archive at the positions given in your input file. (Your file will not be saved on the server; it will be deleted as soon as the cross-correlation ends or the CGI script dies.)

Path to Your Local File
: The pathname to the catalog file on your disk. Your browser will send the contents of this file to the cross-correlator to use as an input catalog. Depending on your browser and your platform, you may need to give the full path to this file (e.g., `/home/kimball/xcorr.lis`).

Column Delimiter
: This is the character that delimits the columns in your file. The choice is currently limited to tab, comma, pipe (or vertical bar), semicolons, and colons. Let us know if you think something else would be useful here.

The cross-correlator currently cannot handle input lists of fixed-length records. When we work out a reasonable interface for this, however, we'll implement it.

RA Column Number, Dec Column Number
: These are the column numbers of the RA and Dec columns within your file. The first column is assumed to be column #1.

Sometimes a catalog will start with a column-delimiting character. For example, if your catalog looks like this:

```
| HD143275 | 16:00:19 | -22:37:16 |
| HD157246 | 17:25:23 | -56:22:38 |
| HD28497  | 04:29:06 | -13:02:54 |
| HD10144  | 01:37:42 | -57:14:10 |
```

then the cross-correlator will think that column 1 is always empty, so you should start counting columns at column #2. Therefore, in this example, the RA will be in column #3 and the Dec in column #4.

Missions
: Select one or more missions with which to cross-correlate your input catalog. You can use the **Show catalog entries that match any/all of the selected missions** selector (see below) to control whether any or all missions have to match and catalog row in order for that row's results to be displayed.

Radius (arcmin)
: The radius in arcminutes on which to cross-correlate the mission with the input catalog. Each mission has its own independent radius. For each mission, a default radius has been chosen that is more or less appropriate for that mission. (Later on, we may break HST up into its individual instruments, treating each one like a separate mission. In that case, these fields will have default values appropriate for that instrument.)

Show catalog entries that match any/all of the selected missions
: When you select multiple missions, you can use this selector to control how a catalog row's results will be displayed: Set it to `any` to show results if the catalog entry cross-correlates with at least one of the selected missions, or set it to `all` to show only those entries that cross-correlate with *every* selected mission. For example, you might set this selector to `all` if you are looking for catalog entries that have been observed with *both* HST *and* IUE, or to `any` to find entries observed with *either* HST *or* IUE.

Display *n* rows per mission
: Use this selector to determine how many rows from each mission will be displayed. When `ALL` is selected, every row found for the mission will be displayed. Optionally, you may use this selector to reduce the number of rows from each mission reported, reducing the length of the results page. The *total number* of rows for each mission will always be reported.

Cross-Mission Search Tools

The forms listed below offer a variety of cross-mission search options using either positions extracted from online catalogs, or user-specified target names or positions. Submitting any of the forms will return a table of entries listing the data available from the MAST archive for the target or targets of interest. The "MAST Scrapbook" form will return a table of representative data sets as well as a set of thumbnail images displaying either a plot of the spectrum or the image.

Form	Help	Description
MAST Scrapbook		Lists and displays representative spectra or images from the MAST archive based on user-specified target name or coordinates.
Single Target quick search		Cross-correlation search based on user-specified target name or coordinates.
Hipparcos Catalog		Make cuts on the Hipparcos Catalog and cross-correlate them with MAST's holdings.
SKY2000 Catalog		Query the SKY2000 Catalog (version 3) and cross-correlate results with MAST's holdings.
Active Galactic Nuclei		Make cuts on our catalog of AGN, derived from the Veron-Cetty and Veron (1996) catalog, and cross-correlate them with MAST's holdings.
Abell Galaxy Clusters		Make cuts on the Abell Galaxy Clusters catalog (including the supplementary southen catalog), and cross-correlate them with MAST's holdings.
User-Supplied Catalog		Upload your own list of equatorial sky positions to cross-correlate with MAST's holdings.

MAST Scrapbook

Search the MAST catalog of representative spectra or images for an astronomical object. Enter a target name or coordinates (see help for other options). Only fixed targets (i.e., no solar system objects) are available. A table of results will be displayed along with thumbnails of images or spectra.

Target: [ ] Data Type : (•) Spectra ( ) Images

Search Criteria: Coordinates

Name Resolver : (ignored for mission target name search) SIMBAD

Search Radius (arcmin): (coordinate search only) 3.0 Max thumbnails per mission: 10

Submit Query | Reset | Help

What's New Help

Overview

In order to allow more specific listings of changes within MAST, the user may now select both the mission and time period for which to view changes. Once these options are choosen, clicking **GO** will generate and display the requested list of changes.

The **What's New** links available from the individual mission pages access the same master list of changes, but the link is hardcoded with the mission name and a time period of 1 year. In other words, clicking the Whats New link from the mission pages will display changes for that particular mission made during the past year.

Mission
: This entry specifies the mission for which to view changes. Besides the current MAST-supported missions (i.e., BEFS, COPERNICUS, DSS, EUVE, FIRST, FUSE, HST, HUT, IUE, IMAPS, ROSAT, UIT, and WUPPE), one may also select ALL (the default selection) or OTHER, which describes general changes not related to a particular mission (note ALL includes OTHER).

Time Period
: The period of time over which to view MAST-related changes, starting from the day the list is generated. The current options include: last month, last 3 months (the default), last 6 months, last year, and all.

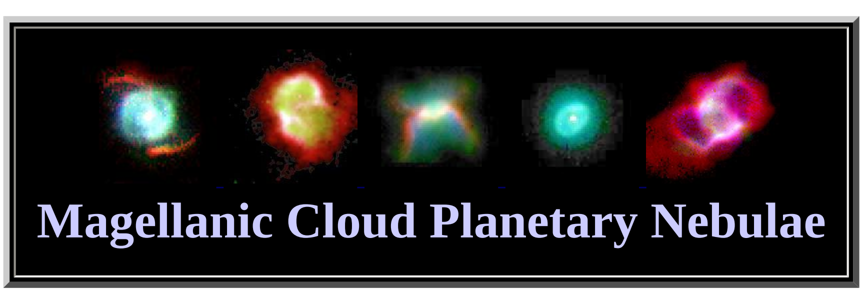
Sloan Digital Sky Survey Quasar Catalog

The Sloan Digital Sky Survey Quasar Catalog consists of 3814 objects (3000 discovered by the SDSS) contained in the initial public release. Each object has at least 1 emission line with a full width at half maximum larger than 1000 km/s, luminosities brighter than M(i*)=-23 and highly reliable redshifts. The area covered by the catalog is 494 square degrees; most of the objects were found in SDSS commissioning data using a multicolor selection technique. The quasar redshifts range from 0.15-5.03.

Calibrated spectra of all objects in the catalog, from 3800-9200 Angstroms, are also available in a gzipped tar file.

Notes: the sample is not homogeneous and is not intended for statistical analysis. The lead author is Donald Schneider from the Dept. of Astronomy and Astrophysics at Penn State University (dps@astro.psu.edu). This sample is the preferred quasar catalog for Sloan analysis, and should supercede the quasar catalog in the EDR.

- PostScript file of the paper as submitted to the Astronomical Journal in October 2001. (1.3 Mbytes)
- ASCII Catalog (0.7 Mbytes)
- A gzipped (compressed) tarfile containing a FITS spectrum for each of the 3814 quasars: edrqsosp.tar.gz (WARNING: very large filesize of 245 MBytes, 623 MBytes uncompressed)
- A web-based EDR QUASAR search interface, developed by MAST, allows you to search the EDR Quasar catalog and retrieve individual spectra. A "simple" and an "advanced" interface are both available. This interface is a generic MAST data retrieval interface, under development by MAST. Comments to archive@stsci.edu are welcome.



Planetary nebulae (PNs) are the gaseous relics of the outermost red giant layers, ejected as a superwind after the Asymptotic Giant Branch (AGB) phase. They carry a wealth of information on the evolution of their progenitor stars, and they retain information on the galaxian environment at the time of the formation of their progenitors. In short, they are the ideal probes of stellar evolution and formation of those stars that undergo the AGB phase.

The importance of studying Magellanic Cloud Planetary Nebulae (MCPN) is twofold: it allows the determination of physical parameters of PNs and their central stars, since their distances are known (as opposed to Galactic PN distances, that suffer large uncertainties); and they are the ideal probes of stellar evolution in low-metallicity galaxies. Small Magellanic Cloud PNs are probably the only direct way to study evolved stellar populations in a very low metallicity environment.

Our project is based on Hubble Space Telescope (HST) imaging with STIS and WFPC2, and optical and ultraviolet slitless spectroscopy. Only with HST can Magellanic Cloud PNs be resolved in their sizes and shapes, and their central stars can be detected. Ground based spectroscopic studies have been used to determine the plasma abundance of the nebulae.

MAST Pointings Help

Help Index:

Introduction

The MAST "Pointings" interface allows a user to search for WFPC2 exposures in a new powerful way. We have assembled a searchable data table that allows users to look for sky regions (or pointings) which have been observed more than N times, observed with 2 or more filters, or has been observed more than twice with a time separation of more than (or less than) N days. An exposure is defined to be the file created after the shutter closes. (So a CR-SPLIT results in at least 2 exposures.) All exposures within a 40 arcsecond radius are considered one "pointing". The total number of exposures within the U, B, V, R, I and for Narrow Line filters were tallied for each pointing. Included in the table are the total number of exposures for a pointing and the number of unique bands. Each band is defined by 3-4 WFPC2 filters (see Table). Filters not in this table, or exposures made with more than one filter were classified as "other" and were included in the total number of exposures. Note that an individual dataset might cover one or more pointings. The table also lists the date/time of first and last exposure for every pointing.

Because the definition of a "pointing" is a little arbitrary, results from this table should be regarded as a starting point for a continued search and subsequent retrieval request.

An example of the kind of query this table will allow is: How many high galactic latitude observations exist [for RA between 9 - 18 hours in the northern hemisphere (dec > -20) observable from the northern hemisphere in the early spring] where there has been at least two observations, and where at least one of those observerations was in the I-band, and at least one of those observations was in any other filter?

Galactic Latitude Above & below plane +/- > 20.0 degrees
Band I >0
Number of Unique Bands >1
Total Number of Exposures >1
RA 09..18
Dec >-20.0

Filter choice for all bands

F380W	F410M	F547M			F658N

Input Parameters

This section describes the options available

Coordinate Query Options
The first section of the search form contains the various coordinate search options that may be included in the query. Note that the RA/Dec range options may be combined with either the galactic or ecliptic latitude options. Entering a target name or specific coordinates for Target Name/Equatorial Coordinates however, may not be combined with the other coordinate search options.

Target Name/Equatorial Coordinates
Enter the name or the coordinates of the astronomical object of interest.
- If you specify the name to be resolved for the "Coordinates" or "Resolved Target Name" search, use standard nomenclature as utilized by SIMBAD or NED for best results.
- For the "Mission Target Name" search mode only, a "%" can be used as a wildcard and all names are converted to upper-case; e.g., entering "r136%" will return all entries in which the mission object name begins with R136.
- To specify coordinates, enter J2000 RA and DEC as decimal degrees or as hours, minutes, and seconds. Several formats will be recognized as coordinates:
  - decimal degrees e.g. 65.4975 19.535 or 65.4975, +19.535
  - hours minutes seconds e.g. 4 21 59.4, 19 32 6 or 4 21 59.4 19 32 6
  - hours minutes, deg minutes e.g. 4 21 19 32 or 4 21, 19 32

Name Resolver
Select either SIMBAD (the default) or NED for name resolution. If the name is not found within either database, try entering coordinates (J2000) instead of a target name. This parameter applies only to the "Target Name/Coordinates" search option.

Search Radius
Enter the coordinate search radius in arcminutes. The default of 3 arcmin will work for many objects, but a smaller radius may be needed in crowded fields. A larger radius may be needed to locate a large extended object. This parameter applies only to the "Target Name/Coordinates" search option.

RA/DEC Range
Specify a start & end RA and/or DEC in decimal degrees (J2000) using the "x .. y" syntax. For example, to search for all pointings between 10 and 30 degrees, enter: **10 .. 30** . Other possible conditions include: **<, >, <=,** or **>=** .

Galactic Latitude
Search on galactic latitude.
- **Above & Below Plane >:** ± Search above or below the galactic plane using designated latitude. e.g. entering 20 in > box will result in search where galactic latitude > +20 and < -20.
- **Within Plane <** ± Search within the galactic plane the galactic plane using designated latitude. e.g. entering 20 in the box will result in search where galactic latitude < +20 and > -20.
- **>** Search where galactic latitude is greater than number entered: e.g. entering 20 in the box will result in search where galactic latitude > 20
- **<** Search where galactic latitude is less than number entered: e.g. entering 20 in the box will result in search where galactic latitude < 20.

Ecliptic Latitude
Search on ecliptic latitude.
- **Above & Below Plane >** ± Search above or below the ecliptic plane using designated latitude. e.g. entering 20 in > box will result in search where ecliptic latitude > +20 and < -20.
- **Within Plane <** ± Search within the ecliptic plane the ecliptic plane using designated latitude. e.g. entering 20 in the box will result in search where ecliptic latitude < +20 and > -20.
- **>** Search where ecliptic latitude is greater than number entered: e.g. entering 20 in the box will result in search where ecliptic latitude > 20
- **<** Search where ecliptic latitude is less than number entered: e.g. entering 20 in the box will result in search where ecliptic latitude < 20

Band
Specify specific bands for the search. If nothing is entered into any bands, bands are not used for search criteria.

Specify if selection is to be on all bands chosen (and) or on any of the bands chosen.
- **And** Select on all bands designated
- **Or** select on any bands chosen
- **U** Enter the number of U band exposures required (e.g. 2, >=2, <10)
- **B** Enter the number of B band exposures required (e.g. 2, >=2, <10)
- **V** Enter the number of V band exposures required (e.g. 2, >=2, <10)
- **R** Enter the number of R band exposures required (e.g. 2, >=2, <10)
- **I** Enter the number of I band exposures required (e.g. 2, >=2, <10)
- **Line** Enter the number of Narrow band exposures required (e.g. 2, >=2, <10)

The filter numbers in the table refer to wavelength in nanometers.

Filter choice for all bands					
U	**B**	**V**	**R**	**I**	**Line**
F300W	F450W	F606W	F702W	F814W	F656N
F336W	F439W	F555W	F675W	F791W	F673N
F255W	F467M	F569W	F622W	F785LP	F502N
F380W	F410M	F547M			F658N

Exposure Times
Enter exposure limits (in seconds) for the total exposure time in each desired band (e.g. >1000, or <10). You may also specify if the search is to be for all specified bands (and) or any of the specified bands (or). For example, specifying "And" and entering >100 for "U" and >100 for "B" will return pointings for which the total exposure times are > 100 seconds in the U filter and > 100 seconds in the B filter. Specifying "Or" would return all pointings for which the total exposure times are > 100 seconds in the U filter or > 100 seconds in the B filter.

Number of Unique Bands
Enter a restriction for the number of unique filters.

Number of Exposures
Enter the number of for the total number of exposures e.g. <30

Number of Days between first and last exposure
Enter the number of days required between the first and last exposure. Entering >365 will look for pointings with exposures taken at least a year apart.

Submit Query
Click on this button to begin the query. The Pointings Tables will be searched for entries which meet the specified search criteria. The result may be none, one, or many objects. You may wish to redo the search with a smaller search radius in a crowded field, or using different search criteria.

Reset
Clicking reset will return the form to its default values.

Maximum Number of Pointings Displayed
The maximum number of rows (i.e., pointings) to be displayed on the search results page. Allowed values are 10, 100, 500, 1000, and 5000. The default is 100. Note displaying more rows will increase execution time.

Help
Clicking help will display this help file. If you still have trouble, please e-mail your question to archive@stsci.edu.

Output

The output of your query will include three parts:

- A summary section including a definition of the query used to interrogate the database, and a summary table containing the total number of pointings found, the total number of unique exposures found, etc. (See summary table heading descriptions below.)
- A table of pointing entrees in which each row represents one pointing matching the users search criteria. See descritpion of pointings table below.
- Links in the above two tables allow a third table to be displayed which describes information about the individual exposures contained in the selected pointing or pointings. (See exposures table description below.)

Summary Table

This table summarizes the search results. Note that clicking on the filter entrees in either the Summary table or the Pointings table will display the individual exposures described by the table entry. The summary table column headings are described below.

Mission/Instrument
The mission and/or instrument from which the data are derived. The table entries will be linked to the appropriate MAST mission home page. Currently only information concerning HST/WFPC2 pointings are avaiable in the pointings table.

# of Pointings
Total number of pointings found for a given query, where a pointing is defined as a group of exposures falling within a 40 arcsecond radius.

Exposures
Total number of **unique** exposures for the specified search criteria (i.e., exposures contained in 2 or more pointings are only counted once).

U
Total number of **unique** exposures taken with a U band filter. (note: since pointings may overlap, this number may be less than the sum of the entrees listed in the "U" column of the pointings search results table).

B
Total number of **unique** exposures taken with a B band filter. (note: since pointings may overlap, this number may be less than the sum of the entrees listed in the "B" column of the pointings search results table).

V
Total number of **unique** exposures taken with a V band filter. (note: since pointings may overlap, this number may be less than the sum of the entrees listed in the "V" column of the pointings search results table).

R
Total number of **unique** exposures taken with a R band filter. (note: since pointings may overlap, this number may be less than the sum of the entrees listed in the "R" column of the pointings search results table).

I
Total number of **unique** exposures taken with a I band filter. (note: since pointings may overlap, this number may be less than the sum of the entrees listed in the "I" column of the pointings search results table).

Line
Total number of **unique** exposures taken with a Narrow band filter (note: since pointings may overlap, this number may be less than the sum of the entrees listed in the "Line" column of the pointings search results table).

Other
Total number of **unique** exposures taken with any filter or filter combination not explicity assigned to a band. (note: since pointings may overlap, this number may be less than the sum of the entrees listed in the "Other" column of the pointings search results table).

Exposure Display Format
Clicking on the filter totals in the summary table will run a script to display the unique exposures for that particular filter and selected search criteria. The default **"retrieval list"** format will display data set names in an html table with options for downloading files. The **"print list"** option displays a comma-separated list of data set names which can be cut and pasted into other data retrieval tools. The **"file list"** option writes the list of data set names (one per line) to a file (dsn.txt) which can be downloaded to the users computer.

Maximum Number of Exposures Displayed
The maximum number of rows (i.e., exposures) to be displayed on the exposure search results page. Allowed values are 50, 100, 500, 1000, and 5000. The default is 100. Note displaying a large number of rows will increase execution time and displaying a large number of buttons may cause some browsers problems.

Found Pointings Table

Each row of the pointings table contains information on the exposures within one pointing. The non-zero "U", "B", "V", "R", "I", "LINE", or "OTHER" filter entries contain two numbers: the total number of exposures taken with a given filter (upper number), and the sum of the exposure times for those exposures in seconds (lower number). Clicking on the upper number will display the exposures table (see below). The pointings table column headings are described below.

Mission/Instrument
The mission and/or instrument from which the data are derived. The table entries will be linked to the appropriate MAST mission home page. Currently only information concerning HST/WFPC2 pointings are avaiable in the pointings table.

RA (2000), Dec (2000)
The right ascension and declination in J2000 epoch as defined for a particular pointing.

Galatic Latitude and Longitude
The galactic latitude and longitude as listed in the pointings table, as calculated from the J2000 ra and dec in the mission catalog.

Ecliptic Latitude and Longitude
The ecliptic latitude and longitude as listed in the pointings table, as calculated from the J2000 ra and dec in the mission catalog.

Angular Separation
When performing equatorial coordinate searches, the angular separation (radius), given in arcminutes, between the SIMBAD (or NED) coordinates and the coordinates listed in the pointings table.

Total
Total number of exposures counted for the pointing.

U
Total number of exposures taken with "U band filters" counted for the pointing.
B
Total number of exposures taken with "B band filters" counted for the pointing.
V
Total number of exposures taken with "V band filters" counted for the pointing.
R
Total number of exposures taken with "R band filters" counted for the pointing.
I
Total number of exposures taken with "I band filters" counted for the pointing.
Other
Total number of exposures taken with any other filter or filter combination for this pointing.
Line
Total number of exposures taken with "Narrow band filters" counted for the pointing.
Unique
Total number of unique bands within this pointing.
First Date
The date of observation the earliest exposure for this pointing was acquired.
Last Date
The date of observation the latest exposure for this pointing was acquired.

Exposures Table

This table lists the individual exposures and data set names associated with the pointings selected from the pointings search results page. Options on the search results page control both the page format (i.e., html table or comma-separated list), and the maximum number of entries displayed. The html table format allows the display of preview images and data retrieval. Column headings are described below.

Row
The row number in the results.

Mark
Mark this dataset for retrieval by pressing this checkbox. After you have marked for retrieval all the datasets that you're interested in, hit the **Retrieve Marked Datasets for Retrieval** button to initiate the retrieval.

Dataset Name
The unique identifier for an HST observation. This value is hyperlinked. By clicking on it, you can display a preview image of the observation.

Target
The name of the target of the observation, as given by the proposer.

PEP ID
The ID number of the observing program. Clicking on an entry in this field will display the HST proposal search page containing the proposal title, PI's name, abstract, ads links to published papers, and a table of all known observations.

Occasionally, you will see target names like `PAR`, `UNKNOWN-TARGET`, and so on; these are (most likely) parallel observations, which are observations done by one instrument while another is making the primary observing of the telescope's visit.

RA
The equatorial right ascension of the instrument aperture, in equinox J2000.

(For the WFPC2, the aperture right ascension coincides with the V1 right ascension, which is the middle of the field of view.)

Dec
The equatorial declination of the instrument aperture, in equinox J2000.

(For the WFPC2, the aperture declination coincides with the V1 declination, which is the middle of the field of view.)

V3 Position Angle

The V3 position angle (PA_V3) is the direction in degrees east from north that the tip of the L shape formed by the 3 WF chips would point, if the L shape is imagined to form the tip of an arrow. (see WFPC2 Position & Orientation). The V3 position angle is 180 degrees different (exactly opposite in direction) rom the U3 position angle, which is specified by the observer during the Phase 2 proposal process as the "ORIENT".

Exposure Time
The exposure time of the observation, in seconds.

Filter
The HST filter used for the observation.

Observation Date
The starting date and time of the observation (GMT).

Release Date
HST data has a nominal proprietary period of one year (though in special cases, this may be shortened or extended). The Release Date field gives the end of the dataset's proprietary period.

On-the-Fly Reprocessing of HST Data

Welcome to the STScI OTFR WWW site.

Through OTFR, Hubble archive users can obtain data that are processed with the latest calibration files, software, and data parameters. The OTFR system reconstructs the data files with update headers and calibrates data when processing a user's request for the data from the archive. WFPC2, NICMOS, and STIS data can now be retrieved with OTFR system.

The raw data returned to users through OTFR is reconstructed from telemetry files to include updates to data parameters.

The following links provide information for users:

- Instructions

What's New for MAST during last 6 months

- **WUPPE Added to MAST Scrapbook**
  2002 March 15
  Representative spectra from the ASTRO WUPPE mission have been added to the MAST scrapbook available at http://archive.stsci.edu/scrapbook.html

- **New WUPPE Preview Files**
  2002 February 28
  The WUPPE Preview files have been updated following the format adopted for the other MAST missions. Besides a plot showing flux, polarization, and polarization position angle as a function of wavelength, there are now links to display the FITS header, display the ASCII table file, display/customize a plot of flux versus wavelength, and download data in FITS format. Links to known literature references are also displayed.

- **More MAST mission data now on-line**
  2002 February 27
  All IUE, UIT, BEFS and VLA-FIRST data are now on-line on a RAID array. The response time for data downloads for these missions should improve significantly. Data for missions HUT, WUPPE, TUES, and Copernicus were already on-line. HST and FUSE data remain on DADS and response times for data download for these two missions are not affected. EUVE data are held at HEASARC and this data is also not affected.

- **Larger Staging area for HST and FUSE data**
  2002 February 27
  The staging area for HST and FUSE data retrieved with the HOST option has been significantly increased to around 500 GB from 27GB.

- **Name Resolver Option Available in Cross Correlation search**
  2002 January 15
  The cross correlation search option available from the top MAST page now allows a choice of NED or SIMBAD for resolving user-specified target names. (The previous version only used SIMBAD.)

- **New MAST/ADS Data Links**
  2002 January 11
  The ADS data links to data archived winthin MAST have been revised. Now a link to a single MAST page is shown which displays all the known MAST references for a single bibcode. (See 1995ApJ...449..488R as an example.)

- **Coplotting Option now available for IUE Spectra**
  2001 December 10
  A new option is available on the search results page of the IUE search script which allows users to coplot up to 15 selected IUE spectra and interactively rescale the resulting plot.

- **New Interface for SDSS EDR Quasar Data**
  2001 December 3
  A web-based search and spectra retrieval interface for the SDSS EDR Quasar catalog and spectra, is now available at http://archive.stsci.edu/sdss/quasars/. The interface is based on a generic MAST interface we are developing and comments and suggestions, as always, are welcome at archive@stsci.edu.

- **Magellanic Cloud Planetary Nebulae Data Sets now Available**
  2001 November 15
  HST prepared datasets of the Magellanic Cloud Planetary Nebulae are now available.

- **HST Literature Links Update**
  2001 November 13
  The HST reference database table entries (and ADS data links) are now complete through the first half of this year.

- **EUVE Previews Updated**
  2001 October 24
  Preview files were made available for the last 83 EUVE observations obtained in 2000 and 2001.

- **New Plotting Option Offered in MAST Scrapbook**
  2001 October 18
  A new option for coplotting multiple spectra and adjusting plot scales is now available in the MAST scrapbook.

- **Exposure time searches offered for WFPC2 Pointings**
  2001 September 27
  The WFPC2 Pointings search form now allows searches to be performed on total exposure times. See the pointings help page for more information.

- **OTFR Implemented for NICMOS Data**
  2001 September 26
  As of today, all requests for archived NICMOS data will utilize the On-the-fly Reprocessing (OTFR) system.

FAQ Help

Overview

Welcome to the MAST Frequently Asked Question (FAQ) help page. If you don't see an answer to your question, or have suggestions for adding new FAQs, please contact the archive help desk at the e-mail address shown at the bottom right of this page.

The FAQ links on the various mission pages will display all the FAQs specific to that mission. A form shown at the top of the FAQ page however will allow FAQs from other missions and/or specific categories to be displayed. To use the form, simply select the mission and/or category from the menu list and click "GO".

Mission/Category

This entry specifies the mission for which to view FAQs. Note that for some missions, the MAST pages simply link to FAQ pages maintained at remote sites and will therefore have a different appearance and format. This currently applies to FUSE, VLA-FIRST, and ROSAT. MAST FAQs currently exist for the remaining MAST-supported missions. A general FAQ page also exists for MAST itself.

If a category follows the mission name separated by a "/", only the FAQ's for that particular category will be displayed. If only the mission name is selected, all the missions FAQs will be displayed.

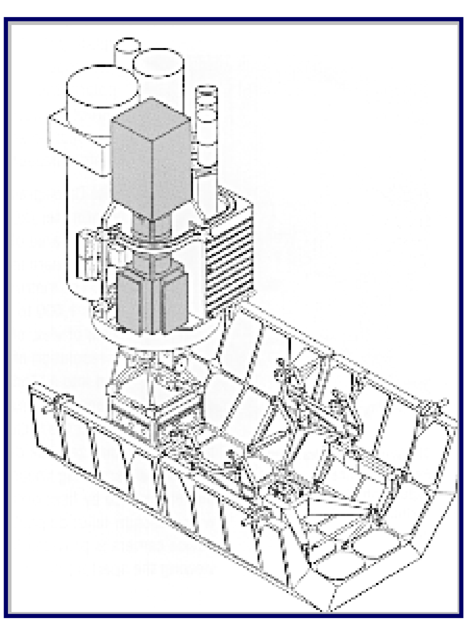
Instrument Description

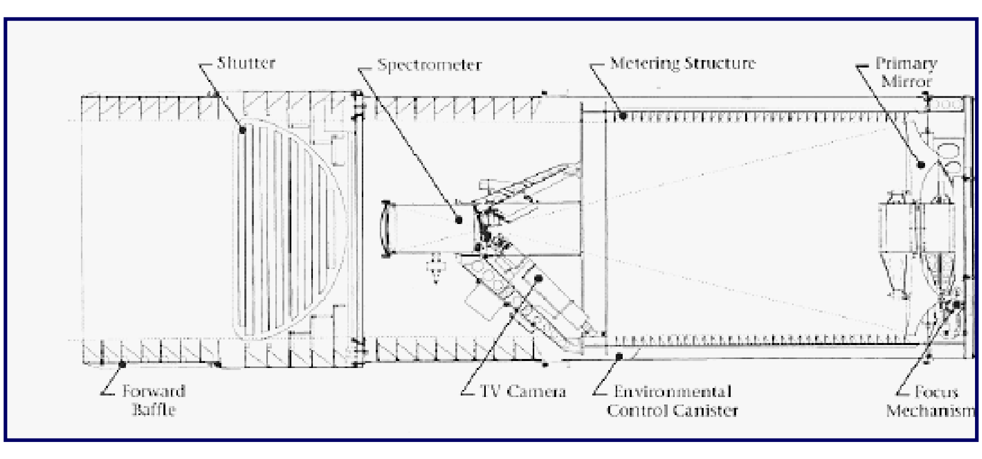
- **Developing Institution:** *University of Wisconsin*
- **Telescope Optics:** *Cassegrain system, f/10 focal ratio*
- **Instrument:** *Spectropolarimeter with dual electronic diode array detectors*
- **Primary Mirror:** *50 centimeters (20 inches) diameter*
- **Field of View:** *3.3 x 4.4 arc-minutes*
- **Spectral Resolution:** *6 angstroms*
- **Wavelength Range:** *1,400 to 3,200 angstroms*
- **Magnitude Limit:** *16*
- **Weight:** *446 kilograms (981 pounds)*
- **Diameter:** *70 centimeters (28 inches)*
- **Length:** *3.7 meters (12.14 feet) length*

WUPPE was designed to obtain simultaneous spectra and polarization measurements from 1400 to 3300Å. WUPPE has a 0.5m f/10 classical Cassegrain telescope (area = 1,800 square centimeters, 279 square inches) and a spectropolarimeter, with a field of view of 3.3 by 4.4 arc-minutes and a resolution of 6 angstroms. The telescope feeds light to a low resolution spectrometer equipped with various polarimetric analyzers. The spectrometer is a modified Monk-Gilleson spectrometer: two rotating wheels are used to select the focal plane aperture and the polarimetric analyzer; a magnesium fluoride Wollaston polarizing beam-splitter placed between the aperture and the relay mirror splits the beam into two orthogonally-polarized spectra which fall on the detector. The detector consists of dual Reticon self-scanning linear arrays of 1024 pixel photodiodes (to detect both beams simultaneously) coupled by fiber optics to a microchannel plate intensifier with a cesium-telluride photocathode. A charge-coupled device camera is provided for target acquisition and for viewing the aperture during a measurement. The focal plane scale is 26 arcsec/mm and the dispersion is 78 Å/mm, blaze at 2000 Angstroms. A set of halfwave plates at 6 different angles provided spectropolarimetric modulation with 5 angstrom resolution on point sources through apertures from 6 to 40 arcsec. A "Lyot" analyzer was used to provide 50-100 angstrom spectropolarimetric resolution on faint point targets and diffuse nebulae.



Page taken from WUPPE Web site

Instrumentation and Operations



Principal Investigator:	Dr. Arthur F. Davidsen
Developing Institution:	The Johns Hopkins University
Telescope Optics:	90-centimeter (36-inch) aperture, f/2 focal ratio, silicon carbide-coated, parabolic mirror
Spectrograph:	Prime-focus, Rowland-circle design using a 600 line/mm grating coated with silicon carbide
Spectral Resolution:	3.0 angstroms
Wavelength Range:	825 to 1850 angstroms (first order)
	420 to 925 angstroms (second order)
Detector:	photon-counting
	microchannel-plate intensifier
	cesium iodide photocathode
	1024 element photo-diode array detector
Time Resolution:	1 ms in high time mode
	2 s in histogram mode
Dark Count Rate:	0.001 counts/Angstrom/s
Peak Effective Area:	35 sq. cm at 1200 angstroms
Sensitivity:	S/N of 10 per Angstrom in 1800 s for Flambda=3.3e-14 ergs/cm2/s/A
Weight:	789 kilograms (1736 pounds)
Dimensions:	1.1 meter (4 feet) diameter
	3.7 meters (12 feet) length
Field of View of Guide TV:	10 arc-minutes

The Hopkins Ultraviolet Telescope (HUT) was designed and built by members of the Center for Astrophysical Sciences and the Applied Physics Laboratory of The Johns Hopkins University in Baltimore, Maryland. HUT consists of a 90-centimeter (36-inch) f/2 mirror that focuses light from celestial sources onto a prime focus spectrograph.

Covering the 825-1850-angstrom region with about 3-angstrom resolution, HUT opened the astrophysically important 912 to 1200-angstrom window to detailed scrutiny for the first time. In typical 1800 s integrations, HUT observed faint astronomical objects with visual magnitudes of about 16.

Originally designed to explore the far- and extreme-ultraviolet ranges on Astro-1, HUT was modified for Astro-2 to concentrate on the far-ultraviolet. The changes made to HUT for Astro-2 included a new detector system and new silicon carbide coatings on the mirror and grating which replaced the original iridium and osmium. These improvements provided a factor of 2.3 increase in sensitivity in the primary operating range of 825 to 1850 angstroms, especially in the 912- to 1200-angstrom region unique to HUT.

HST Archive Answers

Who do I contact for help with proposal preparation?

STScI is maintaining a hotseat from 9:00am to 5:00pm Eastern Time at 410-338-1082 or (toll-free in the U.S.) 800-544-8125, and e-mail to help@stsci.edu. There is also the ST European Coordinating Facility, at 49-89-320-06-291, email: stdesk@eso.org, as well as a list of contacts in Appendix A of the Call For Proposals.

If you have a question regarding Archive facilities used in preparing your proposal (such as duplication checking or the Planned and Archived Exposures Catalog), please contact us at archive@stsci.edu

back to top

Can I do duplication checking on the web?

You can use the web-based duplication search to do check you proposals for duplication conflicts. Duplication checking is still available via StarView.

back to top

Why can't I log into archive.stsci.edu as `guest` ?

The archive guest account has been discontinued. You can install StarView6 on your machine. You can also use the Web form. If neither of these approaches is sufficient to meet your needs, please let us know.

back to top

How do I get the latest FOS calibrated data?

Improved calibrations for FOS data are available using STSDAS software available from the www.stecf.org web site. Additional FOS information is also available from this site.

back to top

How can I retrieve HST data?

You'll need to register for a retrieval account. Your retrieval account will give you access to any science, calibration, or engineering data in the Archive. PIs need a special authorization attached to their retrieval accounts which allows them to retrieve proprietary data from their own proposals; see this answer for details. You can retrieve public data using one of the

following options:
- by installing and running StarView6 at your site;
- by using the HST Archive Search on the Web;
- The archive guest account has been discontinued.

The data can be retrieved either to the staging disk using the `HOST` option or directly to your own site using the `NET` option. Both options are now available via StarView6 or the HST Archive Searches on the Web.

If you use the `HOST` retrieval option, DADS will retrieve the data to the staging disk of the host machine listed in your retrieval completion message.

If you use the `NET` retrieval option, you will need to specify the machine address, login, password and directory where you wish the data to be retrieved.

> DADS will ftp the data directly to a directory on your computer. (Note that we protect your destination information when it is transferred to us with the same kind of secure-web mechanism that is used by commercial sites conducting online commerce.)

Note that the `NET` option is the only one available to retrieve proprietary data across the internet.

If internet transfers are not feasible, both public and authorized proprietary data can also be retrieved to tape-- just use the `TAPE` retrieval option. We will ship it to the address given in your account registration.

back to top

I'm the PI on proposal xxxx. Can I use StarView or the Web to retrieve my data?

We're happy to tell you that you can! You can have your retrieval account set up so that you will be able to retrieve proprietary data from those proposals directly to a directory on your home machine.

Just send an email to archive@stsci.edu. Please note the proposal id's, and designate any others who you believe should have access to the data.

You can't retrieve *any* proprietary data to the Archive hosts; it has to be delivered to your machine using the `NET` option or to tape using the `TAPE` option.

You can also designate your co-investigators for this privilege.

back to top

I'm the PI on proposal xxxx. Why can't I retrieve the data?

You can, but you'll need to let us know you want it. Currently, PIs do not receive automatic electronic access to their data. (This is a technical limitation, not a policy.) If you are the PI and want electronic access to your proposal, contact *archive@stsci.edu* and let us know the proposal ID and your archive username. We will attach the proper access privileges to your account to allow you to retrieve this data electronically.

You can also authorize co-investigators and co-workers to have electronic access as well. Just tell us the proposal ID and the names and archive usernames of those to whom you wish to grant access. (If they don't have accounts, or you're not sure if they do, then let us know their email addresses to we can help them set up accounts for access.)

Authorization may be set up only on a per-proposal basis; we cannot restrict access to certain data within the proposal.

back to top

How do I get permission to retrieve my proprietary data and documents?

We ask that the PI send us an email (to archive@stsci.edu). In that email, note the proposal id's, and designate any others who you believe should have access to the data.

Once an individual is authorized for a particular proposal, they have access to all proprietary data in that proposal only.

Be sure to use the *`NET`* retrieval option!!

If while retrieving your data you get a message saying that the data are still proprietary, one of the following has happened:

- You are trying to retrieve the data to the Archive Host staging disk. The staging disk is an anonymous FTP area, so we can allow only non-proprietary data to be written to it. Have the data sent directly to your disk or sent to you on tape instead.
- We made a mistake and didn't properly authorize your account. This may be particularly true if you (for some reason) have more than one archive account.
- The data are under restriction, which means that they were found to duplicate planned or existing proprietary observations, and an access restriction has been placed on them until the data with which it conflicts is released.

back to top

I forgot my password...

Don't worry, it happens to the best of us. Just call the Archive Hotseat and we'll reset it for you.

back to top

How long should a retrieval take?

The retrieval time depends on a variety of factors:
- the type of data in the request. Some older data is stored offline and requires an operator's intervention.
- the size of the request- the larger the request the longer it takes, both to move the request up the queue , and to retrieve the data.
- the number of requests in the system at the time.
- the destination of the request. The internet connections between STScI and some sites, especially those overseas, is sometimes a significant source of delay.

If everything is running smoothly, expect a median turn around time of a few hours. If it takes more than one day, and you don't think any of the factors listed above are playing a significant role, please contact us.

back to top

When I submit a request, it fails immediately, telling me my host password contains forbidden characters

There are 5 characters that are forbidden:
( ) * " /
In order to successfully submit a request, you will need to change you password to something not containing those characters. We hope to fix this eventually, as it can be a significant inconvenience.

back to top

I submitted a retrieval, but never got a notice that my request was submitted and queued...

DADS may be down, so it's not reading its mail. The way a retrieval works is that StarView emails the request to DADS. (If you have your mailer set to automatically log outgoing mail, then you'll see these requests, in their encrypted form, in your outgoing mail folder.) DADS then reads its mail and puts your emailed request onto the retrieve queue.

If DADS is down, or is not reading its mail for some reason, then your message will be held in the folder until DADS comes back up, when it starts reading its mail and queueing requests again. That's when you'll be notified.

back to top

I tried retrieving some data, but the staging disk is full...

Fortunately, this doesn't happen as often as it used to, since we installed a bigger staging disk on one of the Archive host machines. (You can check its capacity to be on the safe side.) However, if it does, you can either contact the Hotseat and we'll see if we can do anything to make room (usually by contacting other users and asking them if we can delete their data), or by resubmitting the request and having the data delivered directly to a directory on your home machine (`NET` option), rather than onto the staging disk.

back to top

My request failed. Now what do I do?

If it failed for a reason you can identify (such as a mistyped password/directory/login or no space left on destination device) go ahead and resubmit the request with the necessary alterations. Once a request fails in DADS, it is dropped from the system.

We do not resubmit failed requests for users, you will need to do that yourself.

If the failure occurred for a reason that isn't clear, contact the Archive hotseat with a description of the failure and we will investigate.

back to top

I submitted a request two days ago, and it hasn't finished yet.

Chances are it won't finish. Retrievals may have crashed and taken your request with it. We will contact you when that happens, but sometimes we may not be able to.

DADS retrieval times are dependent on the size of your request, the destination you specified and the number of requests in the system. A median retrieval turnaround time is a few hours, so if your request has taken more than a day without you getting a completion message, contact the Archive Hotseat and ask about your request. It has been our experience that users outside the United States sometimes experience longer retrieval times.

back to top

How can I find out how my retrieval's doing?
UPDATED

Via the web, you can check the status using a simple tool at http://archive.stsci.edu/cgi-bin/reqstat.

back to top

I retrieved some data and got a notice that it was ready. Where is it?

If you selected the `HOST` option in StarView or on the Web then the data was retrieved to the staging disk of stdatu.

It has a "lifetime" on that disk of about 3 days.

Use anonymous FTP to get your data (ignore the `/stdatu/dads_stage` part of the pathname).

If you selected `NET` as the media option, then the data will have gone to the node name and directory you gave to Starview as the destination directory.

back to top

I don't want the data I just requested. Can you kill this request?

Once the request has been queued, we can't kill it-- at least, not without bringing down retrievals completely.

back to top

Can I get the data in (GIF/JPEG/whatever) format?

The data are delivered from the Archive in multigroup Flexible Image Transport System (FITS) format only. We currently do not support conversion to other formats; you will have to do this yourself.

back to top

How do I display data in FITS format?

There are various FITS readers available. For example SAOimage (ds9), which can be retrieved via anonymous FTP from sao-ftp.harvard.edu in the directory /pub/rd/ds9, runs on various systems. More information on HST data and data analysis software is available on-line (in particular, see the HST Data Handbook).

back to top

I know I have an account on stdatu, but I can't log into it any more...

The Archive guest account has been discontinued. Users should either:

- Install StarView6 at their home sites
- Use the Web tools for searching the catalog and retrieving data

If neither of these options meet your needs, please contact us at archive@stsci.edu.

back to top

I don't need the whole dataset. How do I retrieve just one file extension?

With the current OTFR system, this is not possible. You will get a `Dataset` `does not exit` error. For instruments not using On The Fly Calibration or Reprocessing, it will still work.

This option will eventually be reactivated.

We recommend not using it in the meantime.

As of May 15 2000, ST ScI stopped archiving calibrated WFPC2 data. For datasets archived after this date, selecting a calibrated file extension will return a dummy file containing no data. Use the On-The-Fly Calibration option to retrieve calibrated data for WFPC2 datasets archived after May 15 2000.

back to top

StarView6, a Java application released

NEW

Developed in Java, StarView version 6 provides an easy to use, highly capable user interface that runs on any Java enabled platform as a standalone application.

You can download and install it. It requires Java 1.2 or higher to run.

The old StarView 5.4a has been discontinued. All x-windows and crt-versions of are no longer functional. Users will need to switch to StarView6.

back to top

Does StarView run on platform X?

StarView6 needs a system that has a Java 2 Runtime Engine. You will need to make sure that you have a version of Java that is 1.2 compliant. See download and install links for more information

back to top

Can I install the StarView software on my machine?

Yes. StarView6 is available from the web.

back to top

Can I get the source code for StarView and compile it on my machine?

Please use StarView6.

back to top

How do I run StarView?

You can install StarView6 and run it from your home site.

back to top

I need to run StarView on archive.stsci.edu. Why can I not login with my archive user id and password?

The Archive guest account was been discontinued. Users should either:

- Install StarView6 on their home sites
- Use the Web tools for searching the catalog and retrieving data

If neither of these options meet your needs, please contact us at archive@stsci.edu.

back to top

When I try to start StarView5.4 (xwindows distributions), it crashes immediately. What is wrong?

StarView 5.4 is now obsolete. Please install StarView6.

back to top

I need to recalibrate some data. Can I retrieve the calibration files?

back to top

Yes. In Starview, for each instrument, there is a calibration screen that will show you what files the dataset was calibrated with, and which files you should use if you are recalibrating. Each of these screens has special buttons to mark the used or recommended calibration files for retrieval.

If you already have the names of the files you want, then you can retrieve them directly. Go directly into the Retrieval screen through the Commands menu and use the "Add dataset by name" or "Add datasets from file" options. In the "File Options" screen, just press the "Calibrated" (or "OTFC" for STIS or WFPC2) button. That will ensure you get the right files.

Via the Web, select the appropriate choice from the Retrieval Options page: "Best Reference" or "Used Reference" files.

To search for specific calibration files, you will need to know the names of the files and search for and retrieve them using the Dataset List Search page.

back to top

How do I find observations of an object by name?

You can try entering this in the "Target name" field of a search screen, but the target names in our database are chosen by the proposer, so they might be a little (or a lot) different than you might guess.
The best way to search for a specific (fixed) target is to use the "Get Coordinates"/Resolve button. Press this button and a window will pop up asking you for a target name. When you enter a target name and search, it will resolve the target names into RA and Dec through SIMBAD or NED. It will then enter the target's RA and Dec on the StarView screen, along with a 10-arcminute search radius (which you can change, if you want). (If you do a lot of extragalactic work, you can choose the NED resolver instead of SIMBAD.)

For solar-system targets, you may still need to search by target name. In this case, it would be wise to wildcard the target name. For example, to search for observations of Jupiter, enter `*JUP*` into the target name field. Also, you can constrain your search to solar-system proposals by entering `Solar System*` in the "Description" field, if there is one on the screen. (Note the wildcard!)

back to top

How do I find all the observations for a class of objects (like Seyferts?)

Specify a target description. Pull down the "Help" menu and select "On Targets". This help topic will show you how to search for observations of classes of objects. There is also an up-to-date list of target descriptions currently in the HST Archive.

back to top

Can I use StarView or the Web to cross-correlate a list of my targets?

Both StarView and the web offer cross correlation.
There are instructions on how to use the StarView cross correlation in the online StarView help documentation.

Cross correlation is also available on the web at http://archive.stsci.edu/search/. There are help texts that describe how to use this function.

back to top

I had some observations made recently, but I haven't yet received a tape...

As of August 1, 2000, we are no longer generating tapes for proposals. If you wish to have a tape of your data, please submit a retrieval request as you normally would, and use the TAPE retrieval option.

back to top

Can I have multiple copies of a tape made for my collaborators?

Because of the volume of data that we handle, we can only make one copy of the data. However, see the question about PIs retrieving their own data for information on how to let your CoIs retrieve the data from the Archive directly.

back to top

Can I get my tapes sent via a next-day carrier?

All tapes are sent out via FedEx Next Day Air by default.

back to top

How do I generate paper products myself?

- We offer paper products electronically in PDF format. As of **August 1, 1999** we no longer manufacture hardcopies of the paper products, but will still provide them for extreme need cases. Please contact us if this is the case.

  Users will need to retrieve their paper products using the PDF Search Page

  Files are password protected (unless the proposal is a calibration program) and users will need their archive name and password to access documents (as well as authorization to access the proposal). This interface is not intended for general archive users but specifically for PIs of HST programs.

- You can also generate paper products from your data using a task in IRAF/STSDAS called pp_dads.

back to top

Where can I get the Archive Manual?

- The ***Archive Manual*** is also available on-line.
- The ***HST Data Handbook*** can be found here.
- You can get these via anonymous FTP from:
  - ftp.stsci.edu, in the directory `archive-html`
  - archive.stsci.edu, in the directory `pub/manuals`
- You can also use our document request form to order printed copies (they're free), or just contact the Archive Hotseat.

back to top

How do I find out the latest versions of the Archive Manual?

We will keep the most up to date manual we have available on-line.

back to top

Is there an Archive Newsletter?

Yes. The electronic newsletters provide information about the various archives supported by the Multi-mission Archive at STScI (MAST). In addition to HST data, MAST also provides support for VLA First, IUE, Copernicus, and EUVE data. Data from the FUSE, Astro-1 and Astro-2 missions for the UIT, HUT, and WUPPE instruments will be added in the future.

It is sent out electronically to a distribution list. You can also read it on-line.

back to top

Where do I find the ASCII catalogs, namely the AEC and PAEC?

The ASCII catalogs are online at http://archive.stsci/hst/catalogs.html.

back to top

How often are the catalogs updated?

The AEC is updated monthly. Check the file README.AEC for the date through which the AEC is complete.

The PAEC and proposal catalogs are usually done once or twice each proposal cycle.

back to top

What does this error message mean?

`General FTP error`: Transfer failed due to ftp errors. If it isn't clear from the code and comments what caused the error, and it continues to occur, please contact us and we will investigate.

`File not found`: Usually a result of a hardware error on our end. You can resubmit the request and usually the problem goes away. If it doesn't, please contact us.

`File not processed`: If you receive this error and cannot subsequently retrieve the data, please let us know.

`Dataset does not exit`: This can result when you have submitted a request using the customize retrieval options, or have edited your request file. Double check that there are no errors in the filenames, classes and extension you requested. If you are certain that this file should exist, please contact us and we will look into it.

back to top

Frequently Asked Questions

---

1. Why do I get 2 IUESIPS MELO files for some low dispersion images but only 1 NEWSIPS MXLO file?

- In IUESIPS, the extracted data for large and small aperture data from a given image were archived as two separate files (e.g. MELO1 and MELO2). In NEWSIPS, the extracted data for both apertures were archived in the same FITS file (e.g. MXLO).

2. Can I request IUE data in ASCII format?

- ASCII versions of the mxlo and mxhi files are available. From the search results page click on the object name to display the preview image. The ASCII versions can be downloaded by clicking on the line "Download a gzipped ASCII file of the large/small aperture preview spectrum." This line is found at the bottom of the preview page. If the image contains an exposure for both apertures, there will be a line and file for each aperture.

3. Why are some IUE NEWSIPS data not available? The IUESIPS version is available from the archive.

- There are various reasons why certain images may not be available. Some images are have problems that can't be handled by the NEWSIPS software but are glossed over by IUESIPS. Some images were misplaced during the processing and archiving process; we are chasing them down now. If you are interested in a particular image that doesn't seem to be available, please contact us and we will find out and make it available to you if possible.

4. How do I read NEWSIPS files into IRAF?

- The **iuetools** package will allow users to read NEWSIPS files. Currently the package requires IRAF (V2.11 or later), TABLES (V2.0 or later) and STSDAS (V2.0 or later). Here is more information.

5. How do I read NEWSIPS files into IDL?

- IDL programs are available to read in the NEWSIPS files. Use READMX to read either MXLO or MXHI files, and READSI to read either SILO or SIHI files. See the IUEDAC User's Guide for more information.

6. Why are my RDAF-format IUESIPS files unreadable after I transferred them from NDADS to my unix workstation?

- RDAF format files from NSSDC use the VAX VMS floating point data format and must be converted to IEEE format before being copied to a unix workstation. See our helpful hints about file copying from NDADS for more information. (Note however that IUE files are no longer available from NDADS.)

7. Can I use SAOimage to look at NEWSIPS files?

- Yes, it will handle the RI, LI, and SI files but not the VD and MX files. Use the options -fits to tell SAOimage that the files are FITS and -upperleft to display the images in the usual orientation, e.g. saoimage -fits -upperleft SWP12345.RILO. Adding the options -min and -max to scale the dynamic range of the grayscale display is also a good idea.

8. What is the wavelength scale used for NEWSIPS? Is it heliocentric?

- Yes, the wavelengths have been corrected for both the Earth's motion around the Sun and the IUE spacecraft's motion around the Earth, computed as of the start of the exposure. A more up-to-date platinum-neon line library was used to create the wavelength calibration, resulting in some small systematic changes in the wavelength scale compared to IUESIPS. Some other small differences compared to IUESIPS are described in the NEWSIPS Manual Appendix III.

9. I have a NEWSIPS image which may not have been processed correctly (wrong dispersion, wrong exposure time). How can I get a correct version?

- Please let us know; we certainly would like to correct any errors. We have a limited capability to reprocess images through NEWSIPS if there was an error in the processing. Send email to archive@stsci.edu.

10. The wavelengths for the Mg II h and k lines are very different, by almost an Ångstrom, between my IUESIPS and NEWSIPS high-dispersion data. Is this an error?

- The IUESIPS data follows the old convention of giving wavelengths in air for wavelengths greater than 2000 Å and in vacuum for wavelengths shorter than 2000 Å. The NEWSIPS data follow the new convention, also used by HST, of giving all ultraviolet wavelengths in vacuum. The difference is pretty large. For instance, Mg II h is 2802.695 in air but 2803.52 in vacuum, Mg II k is 2795.53 in air but 2796.35 in vacuum, and Mg I is 2851.65 in air but 2852.49 in vacuum.

11. The wavelengths for my high-resolution NEWSIPS spectra seem to be off by almost an Ånsgtrom. What happened?

- The NEWSIPS data follow the new convention of using ultraviolet wavelengths in vacuum. Most IUE data users are accustomed to using wavelengths in air for wavelengths longward of 2000 Å, i.e. all LWP and LWR data. (See also the answer to 10.)

12. Are there ASCII files containing the IUE Merged Log?

- Yes, there are ASCII files with the IUE Merged Observing log. There are several subsets of the observing log available also.

13. When analyzing data, which of the data quality flags should I use to throw out pixels?

- Almost certainly all of the nonzero flags. One can imagine situations (the only spectrum in the archives of your source) where you would want to "look" at a spectral feature which was uncalibrated, on the edge of the camera field, or whose fluxes were extrapolated beyond the highest ITF-calibration level - but even in this regime one would probably not want to try to conduct a quantitative analysis of the feature.

  Users should also be aware that no attempt was made in NEWSIPS to eliminate cosmic rays from the high-dispersion images, and the attempts made for low dispersion probably err on the conservative side. The reason for this was a concern that a provision for cosmic rays would lead NEWSIPS inadvertently to remove actual emission lines. Users should especially be cautious about the influence of oblique, diffuse cosmic rays, which can subtlely affect the background surface by 150 pixels or more from the centroid of the "hit" region and be responsible for less than optimal fits to the background surface. We suggest that the SIHI or SILO images be first visually screened before the extracted spectra are analyzed.

14. When coadding like spectra, should I weight the constituent spectra by exposure time or the square root of exposure time?

- Probably neither. An analysis of the noise properties of the IUE cameras for IUESIPS (e.g. as given by Ayres, PASP, 102, 1420, 1990 and PASP, 105, 538, 1993), but probably also applicable to NEWSIPS, suggests that the signal to noise gain is an increasing function of exposure time, but which is slower than either the limits of Exp_time or sqrt(Exp_time). Of course, the actual situation is even more complicated. For example, for integration longer than the "optimal" exposure time, illuminated pixels saturate and are useless. In this regime the quality of the data quickly *degrades*; saturated pixels can never be used for any purpose.

  For the coaddition of data, we recommend weighting individual spectra by reciprocal of the means of their noise fluctuations. (But in computing such a mean consider only those pixels with zero-value quality flags!) The "sigma" vector is computed by NEWSIPS as an estimate of these fluctuations as a by-product of the flux extraction process. For the extracted MXHI data the estimate for each wavelength pixel is based on predicted fluctuations of extraction slit pixels from the noise model for the same region of the camera. The units of the sigma vector in high dispersion are in "FNs" (Flux Numbers), the same as the *net flux* vector. For MXLO data the sigma vector is derived from the noise model, but it depends also upon the relative illuminations of pixels along the extraction slit. In this case the result is also scaled to units of *absolute flux*.

15. Whew! Is there a simpler way of estimating noise?

- Yes. The time-honored way is to find a stretch of continuum in the extracted spectra which contains no spectral features and is free of pixels of with negative data-quality flag values and then compute the rms formally from its noise fluctuations.

  Since "clean" continuum is not always easy to find, let's consider an empirical procedure which works well even for a spectrum containing features. As long as the flux errors are primarily gaussian- distributed, we can make use of the fact that randomly drawn samples will differ from one another, on average, by exactly one standard deviation. In the computing language IDL, an estimate of the rms may be computed conveniently by a few steps. Defining "*f*" as a spectral flux array taken from pixels near the blaze maximum (so the noise will be approximately uniform along the spectrum) and containing only zero-valued quality flags, we compute the mean point to point fluctuation of two pixels separated by a short distance *n*:

  The distribution of noise fluctuations among these pixels can be obtained from the computation:

  rmsdist = abs(*f* - shift(*f* , *n*)) .

  The median of this distribution is computed by sorting the distribution *rmsdist* and finding the middle element of the sorted *rmsdist* array, which by definition is half the number of elements in the distribution. Thus:

  ntot = n_elements(*rmsdist*), so *ntot2* , = *ntot*/2 ,

  Now we compute the sorted index distribution and take the value of *rmsdist* we need:

  isort = sort(*rmsdist*) ,

  medrms = *rmsdist*(isort(*ntot2*)) . *medrms* is the our noise estimate using the median average.

  The *mean* of the distribution can likewise easily be determined from:

  meanrms = total(*rmsdist*)/*ntot* .

  This value will be biased on the high side if there are outlying fluctuations in the spectrum. In practice the pixel separation distance *n* should be at least a spectral resolution element (3 or more).

Frequently Asked Questions

*** DATA REQUESTS**

- Where do I get Copernicus archival data?
- How do I download the Copernicus Spectral Atlas data?

*** COPERNICUS INSTRUMENTS**

- What are the wavelength ranges of the various Copernicus detectors?
- Did the instrument sensitivity significantly degrade with time?

*** DATA ANALYSIS**

- How do I read a Copernicus FITS file?
- How do I coadd Copernicus Scans?
- How do know what wavelength regions were observed for a particular object?

Where do I get Copernicus archival data?

- At the end of the mission, Princeton provided the National Space Science Data Center (**NSSDC**) with a compact set of data on 9-track tapes as the final archive of the *Copernicus* science mission. The data were formatted in such a manner that special programs were needed to extract the information, bit by bit, from the archive. Under a grant from NASA's Astrophysics Data Program, the **Laboratory for Astronomy and Solar Physics** and the **IUE Data Analysis Center** have converted the tape files into **FITS** format disk files and created an on-line archive of *Copernicus* ultraviolet spectra.

  There is one FITS file of raw scans for each of the 551 objects observed by *Copernicus*. These files can be retrieved from the **raw target list**, the **Copernicus search page**, and via the anonymous FTP at archive.stsci.edu in the **/pub/copernicus/raw** subdirectory. The FITS files containing the raw spectral scans are constructed using a Binary table extension and the proposed "variable length array facility" as described in the NOST FITS Draft Standard. Each row of the binary table contains the data from one spectral scan.

  In addition to the raw data files, coadded contemporaneous scans from the U1 high resolution channel (900-1560 Å) and U2 (900-1650 Å) channel are available from the **Copernicus Coadded Scan search page**, and via the anonymous ftp at archive.stsci.edu in the **U1 coadded scan directory** and the **U2 coadded scan directory** The files are stored as standard Binary table FITS files using fixed length vector fields. The files are intended primarily for quick-look data analysis.

How do I download the Copernicus Spectral Atlas Files?

- The spectral atlas files are available online from the **Copernicus spectral atlas page**. References to the original published papaers are also given. The files can also be retrieved via anonymous ftp at archive.stsci.edu in the **spectral atlas directory**. All the spectral atlas files use FITS binary table extensions with scalar fields.

What are the wavelength ranges of the Copernicus detectors?

- The table below shows the spectral coverage of each detector. Note however that the individual scans generally covered a much smaller wavelength range.

Name	Exit Slit* (Å)	Wavelength (Å)	Step Size* (Å)
1 - U1	0.05	710-1500**	0.025
2 - V1	0.10	1640-3185	0.05
3 - U2	0.20	750-1645	0.20
4 - V2	0.40	1480-3275	0.40
5 - V3	?	3430 (fixed)	-
6 - U3	?	1320 (fixed)	-

*****Note: Exit slit and step size vary slightly with wavelength.
******For brighter stars, the 1500-1560 angstrom range can be scanned with U1 in the first order.

Did the instrument sensitivity significantly degrade with time?

- The principal malfunction in the Copernicus instrumentation was the rapid decline in the far-UV sensitivity. The decision to terminate the spacecraft was based partly on the loss of far-UV sensitivity. The following **figure** shows the relative sensitivity of the high-resolution far-UV phototube U1 from orbits 100 to 44000. A rapid (approximately 50 percent) decline at shorter wavelengths was experienced during the first year followed by smaller declines in subsequent years. The low-resolution far-UV phototube U2 exhibited a behavior similar to that of U1. The near-UV phototubes, V1 and V2, did not exhibit the rapid decline seen in the far-UV phototube. For further information, see the **Final Operations Report**.

How do I read a Copernicus FITS file?

- The raw data sets are probably the most difficult files to read since they use the proposed variable length array facility for storing vectors in a binary table extension. In any event, **<examples>** of how to read all the Copernicus data sets using a variety of FITS readers are available. Many users will want to work with individual scans. Examples of how to work with them are on the **<third example>** page just cited.

How do I coadd Copernicus Scans?

- The IDL program **STACK** allows U1 or U2 Copernicus scans to be coadded. This software was used to create the "quick-look" coadded scan files and is available to users from either the **Copernicus Spectral Scan** page (which currently requires you to know the name of a coadded scan file), or from the browse files accessible after searching the **coadded scan database**. In principle, STACK can coadd any Copernicus scans, however only scans taken close in time and using the same detector can produce meaningful results. For this reason, use of STACK is restricted to addiing or subtracting the existing sets of coadded scans.

How do I know what wavelength regions were observed for a particular object?

- The min and max wavelength for each scan is stored as scalar fields in the raw data sets (note wavelengths could be scanned in either direction, so some vectors are in order of decreasing wavelength). However, to help users determine wavelength coverage for U1 and U2 scans, a **spectral coverage table** was created. This can be a useful tool since most U1 scans only cover a couple of Angstroms, and U2 scans normally covered less than 50 Angstroms. The rows of the spectral coverage table represent the observed targets, while the columns list various wavelength regions. Each entry in the table shows the number of scans obtained in that particular spectral region and is also a link to a gif-format plot file showing the spectral range of each scan within that spectral region.

EUVE FAQ

* **DATA REQUESTS**

1. Where do I get EUVE archival data?

2. How do I get multiple EUVE data sets? .

* **EUVE Instruments**

3. What are the wavelength ranges of the EUVE instruments?

4. What are common EUVE spectral features? (i.e is there any signal here!)

5a. What about the Deep Survey Dead-spot?

5b. What about the Deep Survey's short wavelength response?

* **EUVE PERMANENT ARCHIVE DATA**

6. How do I get started with the EUVE permanent archive data?

7. How do I extract an EUVE Spectrum?

8. I run *euvextract* and get an error: "dispaxis not found".

9. How do I make a Deep Survey Light-curve?

---

1. Where do I get EUVE archival data?

- As of Nov 1997, the EUVE project in Berkeley is no longer delivering EUVE archival data. Events and image datasets, which may be reduced to create spectra and light-curves are available from this web site: click here to search the EUVE archive.

2. How do I get multiple EUVE datasets?

- If you are requesting multiple EUVE datasets, for now (since the data resides at HEASARC) you have to click on each data set or go to their ftp site. We will have a batch option in the future.

3. What are the wavelength ranges of the EUVE instruments?

-

  Spectrometer Range (Ang) Resolution SW 70-190 0.5 Ang MW 140-380 1.0 Ang LW 280-760 2.0 Ang Imagers: 10% Filter Bandpasses (Ang) DS Lexan 67-178 DS Al/C 157-364 ScA/B Lexan 58-174 ScA/B Al/Ti/C 156-234 ScC Ti/Sb/Al 345-605 ScC Sn/SiO 500-740

4. What are the common EUVE spectral features?

- The EUVE spectrometers have some common background features caused by airglow and scattering in the upper atmosphere.

  SW- The short-wavelength spectrometer can have a bright rim at shortest wavelengths (left) caused by scattered Lyman alpha.

  MW- The medium-wavelength spectrometer has a broad feature at 304 Angstroms from geocoronal helium.

  LW- The long-wavelength spectrometer has a broad feature at 584 Angstroms from geocoronal helium, which includes the 304 Angstrom line in second order.

5a. What about the Deep Survey Deadspot?

- There is a region of low gain (the "dead-spot") near the center of the Deep Survey Lexan/B band caused by the Feb 1993 observation of HZ 43. The region is about 2 arcmin in diameter and is described in detail in the EUVE technical memo.

5b. What about the Deep Survey's short wavelength response?

- The short wavelength response of the DS has been investigated to explain large count rates observed from high column sources, like Sco X-1 and has often been termed "X-ray leak". The latest ideas have been summarized in John Vallerga's Memo.

6. How do I get started with the EUVE permanent archive data?

- Once you have obtained events and/or fits images from http://archive.stsci.edu/cgi-bin/euve

  3 steps to read them:

  1) gunzip the files.

  2) read fits files with *strfits* (in *stsdas.fitsio*) (step no longer needed with IRAF 2.11, which allows you to read the fits files with out converting them. And *cep* will run on fits files).

  3) the img file will produce ds,sw,mw,and lw images + good times tables [you can go onto spectral extraction from these or continue and reduce the events files.]

  4) the evt file will produce the equivalent of the old format data (like table0 and so on) tables produced will have the following names: adcnts.tab lw_events.tab orientation.tab sw_events.tab ds_events.tab mw_events.tab quadrant.tab valid_times.tab)

  5) run *cep* to produce qpoe files using the appropriate script in archpipe (in egodata1.16) {Note: Only use "Rebuild DS SourceCentered Archive QPOE" for moving targets}

  6) use qpoe file as before

  Please also see the Permanent Archive Guide EUVE Permanent Archive Data Products Guide

7. How do I extract an EUVE Spectrum?

- In IRAF Use the EUV task *euvextract* on the two dimensional image file (which you get get from the source_date_img.fits file). See also: quick help on Spectral extraction?

8. I run *euvextract* and get an error: "dispaxis not found".

- You are missing DISPAXIS header line. This card was omitted from the EUVE archival format because it is specific to reduction of spectra under IRAF and, unlike the old GO products, the archival data format is not IRAF-specific.

  You can add the DISPAXIS card to an image with the standard IRAF task *hedit* . It will need to have the value '1', meaning the spectra run along the x-axis, as long as you haven't rotated the images.

9. How do I make a Deep Survey Light-curve?

- Quick Help on making a DS Light-curve

archive@stsci.edu

BEFS FAQ

1. Where can I get BEFS archival data?

2. What are the differences between BEFS I and BEFS II? .

---

1. *Where do I get BEFS archival data?*

- Both BEFS I and II data can be obtained by searching the on-line catalog at click here to search the BEFS archive.

  Or by ftp access (please see the obtaining BEFS data page.

2. *What are the differences between BEFS I and BEFS II?*
For BEFS II, two of the four diffraction grating were overcoated with silicon carbide and the instrument electronics were modified for improved imaging at high count rates. Three apertures were added for spectroscopy: 1) with an on-axis 26" hole, 2) a second clear hole displaced by 2.4' and 1.4 times larger for diffuse sky glow or serendipitous spectroscopy, and 3) a large 2' aperture with a tin filter opaque to FUV radiation, but transparent in the EUV and used primarily for observations of epsilon CMa.

Frequently Asked Questions

Where do I get TUES archival data?

- See the obtaining TUES data web page.

Can you explain the TUES file naming conventions?

- Basically names are of the form TUESnnnn_m_o.fits where the target ID ("nnnn") is a special 4-digit target identification number and the observation number ("m") refers to the order in which the exposures (for a given target) were obtained. A third number ("o") indicates several pointings were obtained during a single observation (sometimes to improve the alignment of the telescope). A "_PH" denotes an integration from single photon events recorded onboard but integrated after the mission. See also the TUES file naming conventions described in the data products page.

How accurate are the calibrated flux values?

- A HST archive model of G191B2B http://garnet.stsci.edu/STIS/models/tables/g191b2b_mod_002.tab" was used as a reference for the absolute flux calibration. The calibration was additionally checked with a model of BD +28°4211 (R.Napiwotzki). We guess an accuracy of ±10% for the flux calibration. This is valid, if the object was fully centered within the diaphragm. There are, however, some observations for which the object was not completely centered. The reasons are probably due to temperature drifts of the telescope causing a shift of the alignment. In some cases also slightly wrong coordinates of the target might have led to a decentralization.

What is the wavelength coverage of the echelle spectra?

- The Tübingen Echelle (TUES) obtained moderate dispersion observations (R= 13,000) using an echelle grating including orders 40-61 covering the wavelength range from 910 to 1410 Angstroms.

Frequently Asked Questions

GSC

GSPC

How were the Guide Star Catalogs created?

- The basic steps involved include:
  - scanning and digitizing the Schmidt plate material,
  - image processing,
  - calibration for astrometry, photometry, and object classification,
  - Comparison to external catalogs

What is the difference between GSC-I and GSC-II?

- For a quick summary of the properties of these two catalogs see: http://www-gsss.stsci.edu/gsc/gsc2/CatalogProperites/GSCIIProperties.htm

  The GSC I catalog (version 1.0) was constructed to support pointing and target aquistion for the HST. The catalog contains approximately 19 million stars and other objects in the sixth to fifteenth magnitude range, primarily determined from an all-sky, single epoch collection of 6.4 degree by 6.4 degree Schmidt plates. The Schmidt plates for north of +6 degrees consists of a 1982-1984 epoch "Quick V" survey (IIaD, 20 minute exposure) obtained from the Palomar Observatory. The southern fields consist 0f 50-75 minute exposure IIIa-J Schmidt plates, from the UK SERC J/EJ survey (epoch 1975-1988) and a supplemental 4 minute IIa-D southern Galactic plane extension (epoch approximately 1988).

  For more information on the Schmidt plates used to construct the GSC I catalog see: http://www-gsss.stsci.edu/PlateMaterial/plateMaterial.htm

  GSC 1.1 is the catalog used for control and target acquistion for the HST. The improved catalog corrected a number of known problems in the GSC 1.0. The corrected defects included spurious entries (principally due to false detections on the diffraction spikes of bright objects), grossly incorrect entries for the brighter stars (V<7) that were produced from heavily over-exposed Schmidt images, and different entries for the same object having more than one name because of blend-resolution difficulties, as well as astrometric errors at the plate edges.

  GSC 1.2 An astrometric re-calibration of the GSC 1.1 reducing the systematic errors present in the GSC 1.1 positions. This catalog has not been been installed on the HST Guide Star Selection system, so it must not be used for HST observation planning.

  The GSC II will be an all-sky catalog based Schmidt plates at two epochs and three bandpasses, from the Palomar (POSS I and POSS II) and UK Schmidt telescopes (SERC/UK surveys). This catalog will contain postions, magnitudes, colors and proper motions for all objects to at least 18.5 in photographic F. The construction of the GSC II is in progress. A preliminary catalog, GSC 2.2 is now available.

  The GSC2.2 is an all-sky, magnitude-selected subset of this data that has been extracted to support telescope operations at the GEMINI and VLT telescopes. This Telescope Operations version contains positions, classifications, and magnitudes for 435,457,355 objects. The magnitude limits (18.5 in photographic F and 19.5 in photographic J) were implemented to ensure the photometric quality of the released data. Since bright objects are extremely overexposed on the Schmidt plates, positions from the Tycho-2 catalog were used.

  The final version (GSC 2.3), expected to be released in 2002, will also contain proper motions.

  For more information on the Schmidt plates used to construction the GSC I catalog see: http://www-gsss.stsci.edu/PlateMaterial/plateMaterial.htm

When would one use GSC-I instead of GSC-II?

- GSC-II has not been installed in HST Guide Star Selection system, so it should not be used for HST observation planning.

What material is the GSC II based on?

- See http://www-gsss.stsci.edu/PlateMaterial/plateMaterial.htm#GSCIIPlates

What reference frame is used for the GSC II catalog?

- The International Celestial Reference Frame (ICRF).

What magnitude system is used with GSC II?

- The magnitudes are in the natural system of the photographic plates. See http://www-gsss.stsci.edu/gsc/PlateMaterial/plateMaterial.htm for bandpass information.

How were the positions, magnitudes, and classification selected for objects imaged on more than one plate ?

- Although the database from which the catalog was constructed contains multiple epochs and observations for a given source, the GSC 2.2.0 exported catalog positions, magnitudes, and classifications for each unique source were selected by the following criteria:

  Positions and magnitudes from plate observations were selected by choosing the observation which occurs closest to the plate center prioritized by bandpass F,J,V, and N respectively. Magnitude cutoffs were applied (F=18.5, J=19.5, V=19.5). If the observation occurred at different plate scanning resolutions, the highest resolution (15 um pixels) was selected over the lower resolution (25 um pixels) for each bandpass regardless of plate location. Classifications were assigned by voting observations into star (0) or nonstar(3) codes.

  For more details see: http://www-gsss.stsci.edu/gsc/gsc2/gsc22_release_notes.htm

What epoch was used for positions?

- The positions are at the epoch from the plate that they were taken from. We did not take an average or combine in any way the positions imaged on more than one plate. The positions were selected by choosing the observation which occurs closet to the plate center prioritized by bandpass F, J, V, and N repectively.

How were positions determined for bright stars?

- Since bright objects are extremely overexposed on the Schmidt plates, positions obtained from the Tycho-2 catalog were used (see http://www.astro.ku.dk/%7Eerik/Tycho-2/).

Can you provide the photometric transmission curves ?

- Yes, here (http://www-gsss.stsci.edu/DSS/Transmission%20Curves/transmission_curves.HTML)

What is the GSPC?

- To support the photometric calibration of the Guide Star catalogs, CASB produced the Guide Star Photometric Catalog. GSPC I is an all-sky set of photoelectrically determined BV sequences in the magnitude range from 9 to 15, generally near the centers of the fields of the GSC-I plates. The GSPC II, a joint project between CASB and Osservatorio Astronomico di Torino, is generally an extension of GSPC I sequences to V=19 in B, V, and R passbands based on CCD photometry.

  For more detailed information see: http://www-gsss.stsci.edu/gspc/GSPChome.htm

What is the sky coverage of the GSPC II?

- http://www-gsss.stsci.edu/gspc/gspc2_coverage_map.htm

How do I obtain the GSPC data?

- http://www-gsss.stsci.edu/support/data_access.htm#table

HUT Frequently Asked Questions

The Mission

1) What is HUT and What Does it Do?

- See the HUT project answer.

2) What is the history behind HUT?

- See the HUT history page.

3) Where can I find a HUT Technical Summary?

- See the HUT technical summary page.
- A detailed view of the HUT2 telescope module can be seen in the hardware chapter of the HUT data handbook. or alternatively in the HUT instrument and operations page.

4) What are some major publications using HUT data?

- See the HUT publications page.
- Note also the papers by Kruk et al. on final calibration of HUT 1 and HUT-2 (ApJS, 122, 299) data.

Data Handling

5) How do I retrieve HUT data?

Data retrieval proceeds in much the same way as most other MAST-archived datasets. Go to the how to search HUT data page for instructions and the HUT search page for downloading of data. Data will be returned very quickly in a tarred file consisting of many zipped data files and an ASCII filetypes.txt file explaining some of the contents. For further information go to the HUT data products page.

6) How do I read HUT data?

- See the HUT data reading page.

Data Characteristics

7) What are the instrumental error sources in HUT data?

- Unwanted time-dependent signals (dead time, phosphor persistence).
- Airglow in emission lines (geocoronal Lyman alpha can be the dominant feature in the spectrum).
- Extreme UV contamination (white dwarf only; corrected from model atmospheres estimates).
- Telluric absorption (yes, there is atmosphere above the Shuttle!).
- Flux loss from field astigmatism (extended sources only).
- pointing-jitter errors (jitter corrected every 2 secs).

The calibrated data consist of corrections for all these error sources. See the calibration chapter of the HUT data handbook.

8) Did HUT lose sensitivity during its missions?

Yes, the losses were noticeable on an approximately 48 hour timescale, particularly in the far-UV. This is modeled in Figure 5 of Kruk et al. (ApJS, 122, 299, 1999). By the end of the mission the sensitivity of the detector (CsI photocathode) had decreased by 26% at 912 Å and 5% at 1840 Å.

9) What were the differences between HUT1 and HUT2?

The second mission:

- lasted longer (16 days compared to 8 days; 205 hours of on-target time vs. 40 hours).
- made more observations (385 of 265 targets, compared to 136 of 87 targets).
- had greatly improved pointing stability.
- had less sensitivity to extreme-UV contamination because of SiC coatings on the optical elements.

Frequently Asked Questions

*** DATA REQUESTS**

1. Why does it take so long to download the UIT files?

2. How can I tell which files are fully calibrated?

*** READING FILES**

3. How do I read the UIT data files?

---

1. Why does it take so long to download the UIT files?

- The combined files for each observation are fairly large, about 28 Mb compressed, 51 Mb uncompressed. If you need only one file for a given observation, such as the fully calibrated and geometrically corrected ("G") file, you may wish to obtain it from the anonymous ftp site (see Obtaining UIT Data).

2. How can I tell which files are fully calibrated?

- The easiest way is by the file name. The raw image (digitized densitometer output) filenames end in D, e.g. fuv0345d.fits. The linearized, flat fielded image filenames end in E (no good astrometry solution) and F (good astrometry solution). The fully calibrated, geometrically corrected image filenames end in G.

3. How do I read the UIT data files?

- The image files are in FITS format, with the data stored in the primary arrays. The point-source photometry data are stored in ASCII table extensions, with no primary array. These simple FITS formats should be readable by a variety of FITS readers. See Reading UIT Data for more information.

Frequently Asked Questions

* **DATA REQUESTS**

1. How can I tell whether polarization data, as well as the UV spectrum, are available for a particular object?

* **READING FILES**

2. How do I read the WUPPE data files?

3. How do I convert the Stokes parameters Q and U to linear polarization parameters?

---

1. How can I tell whether polarization data, as well as the UV spectrum, are available for a particular object?

- In the search results page, the polarization and position angle will both be set to 0.000 if no polarization data are available. In this case, only the ultraviolet spectrum is available from the archive. In addition, the FITS file for an observation including polarization data is significantly larger (typically 34560 bytes uncompressed) than one with only spectral data (11520 bytes).

2. How do I read the WUPPE data files?

- The image files are in FITS format, and should be readable with standard FITS readers. See Reading WUPPE Data for more information.

3. How do I convert the Stokes parameters Q and U to linear polarization parameters?

- Linear polarization = sqrt($Q^2 + U^2$), while position angle = 1/2 $\tan^{-1}$(U/Q)

Contents

Using the Web Service

"Is there a way to retrieve DSS images in batches?"

No. We know this would be a convenient service, and we would like to do it, but our jukebox is currently getting over 1500 hits a day (more like a thousand, if you count internal accesses and accesses to the Medium Deep Survey), and potential abuse of a batch service could easily put the jukebox into a perpetually busy state, denying the DSS to everyone.

"What are SIMBAD & NED?"

SIMBAD (in Strasbourg, France) and NED (in Pasadena, California) are centralized astronomical databases that provide services like taking an object name and returning its coordinates. That's how they're used here: to redraw the DSS form with your object's RA and Dec in place, so you don't have to go look them up.

Note: SIMBAD and NED only catalog fixed objects, like stars and galaxies. These databases don't track moving targets, like planets, comets, and asteroids. The Sky Surveys were designed to avoid bright solar-system objects anyway, so there won't be any images in the DSS of Saturn or Comet Hale-Bopp.

Also, remember that NED only catalogs objects outside our own galaxy, like external galaxies, quasars, etc. NED doesn't catalog individual stars or nebulae.

(For you acronym fans, SIMBAD stands for **S**et of **I**dentifications, **M**easurements, and **B**ibliography for **A**stronomical **D**ata; NED stands for **N**asa **E**xtragalactic **D**atabase.)

"I tried to use SIMBAD, but it never came back."

SIMBAD is a wonderful service, but unfortunately, the network connection between Baltimore and Strasbourg isn't the best it could be. Sometimes, the network hangs; other times, SIMBAD is just too busy to answer right away.

If you're looking for extragalactic objects, and SIMBAD isn't working, try NED. Ned is in California, and our network connection is a bit better there.

"Are there other sites that offer DSS services?"

Yes, there are. Here's a partial list.

Exposure and Survey Information

"How can I tell what telescope/filter was used for a given image?"

The data are either from the UK Schmidt or the Oschin Schmidt (Palomar) telescopes. You can tell which survey the data come from by looking at the `REGION` keyword in the FITS header. You can also get the observatory ID from the header keyword `TELESCOP`.

For the First Generation DSS, the emulsion/filter combinations are:

- `XE` - POSS-E RED PLATE,
- `XV` - SERC-V Equatorial extension,
- `S` - SERC-J Survey

(Also, see below about the short-exposure plates near M31 and the Magellanic Clouds.)

For the Second Generation, these are:

- `ER` - 'Equatorial Red' survey (UK Schmidt) IIIaF + RG610
- `XS` - 'Second Epoch Southern' survey (UK Schmidt) IIIaF + RG610
- `GR` - 'Galactic Red' survey (UK Schmidt) IIIaF + RG610 SHORT exposure in galactic plane
- `XP` - POSS-II Red IIIaF + RG610
- `XJ` - POSS-II Blue IIIaJ + GG385
- `XF` - POSS-II Near-IR IVN + RG9

(To get information about individual images, you'll need to get them in FITS format and look at the header. This information is not preserved in the GIF image.)

"What do the pixel values represent?"

Scans in the DSS are digitizations of photographic plates. The pixel values in the scans are a measure of the photographic density of the original plate, which is non-linear with the intensity.

"Is a photometric calibration available?"

Yes. The Catalogs and Surveys Branch (originators of the Digitized Sky Survey and the Guide Star Catalog) recently completed a photometric calibration for the First Generation survey (northern POSS-E, souther SERC-J, and southern Galactic Plane SERC-V).

(There was a crude calibration done on the *southern* SERC plates; see Lasker, B., et al. 1990 AJ 99, 2019. Equation 1 shows this solution. Table V lists coefficients for Palomar, too, but *don't use them!* They were for a Mini-J survey, not the actual POSS.)

"How about the exposure time?"

That's in the `EXPOSURE` keyword in the FITS header. (Note that the exposure time there is in minutes.) All exposures are between 2400 and 4200 seconds.

"What's the plate scale?"

For the First Generation scans, the plate scale is 1.7 arcsec per pixel; for the Second Generation scans, it's 1.0 arcsec per pixel. (The plate scale is derivable from the FITS keywords `PLTSCALE` and `XPIXELSZ` / `YPIXELSZ`).

"What Second-Generation survey plates are currently available?"

A complete list of the plates currently available for the Second Generation survey is available at http://archive.stsci.edu/cgi-bin/dss2list.

Image Anomalies

"What's this funny line/feature/UFO in my scan?"

These images were scanned from photographic plates, so every once in a while, you will encounter a scratch, internal telescope reflection, fingerprint, etc. in your image. So far, none have turned out to be aliens. I'm compiling an informal catalog of regions with plate anomalies, so if you run across one, let us know.

"I have a field near M31 that I know should have a lot of stars in it, but I only see a few."

This field was probably drawn from the special short-exposure plate of M31.

There are three such plates, for the Large Magellanic Cloud, the Small Magellanic Cloud, and M31, exposed for 5 minutes instead of the usual 50 or so:

- `XX001` - The Large Magellanic Cloud
- `XX002` - The Small Magellanic Cloud
- `XX005` - M31 (Andromeda Galaxy)

These plates are in the V band; specifically, they were taken with IIaD emulsion and GG 495 filter.

The Quick V version may look better; you can access it through the Phase II proposal preparation form.

"I tried to get an image of the Orion Nebula, but all I got was a big white spot!"

It worked; you just need to extract a wider image to see it. The Orion Nebula is so big that all a 15'x15' extraction shows you is the very center, which in these scans *is* a big white spot. Go to a bigger scan size (if you don't mind handling the correspondingly bigger image file).

Using the Images

"If I use the DSS in my published research, do I need to acknowledge it?"

We request that you do. The Catalogs & Surveys Branch (CASB) has a recommended acknowledgment.

"Can I use images from the DSS in a CD-ROM or some software that I'm writing?"

If you're using images from the DSS for research, teaching purposes and other non-profit activities, you may use them freely, and we only request that you acknowledge the source. Commercial applications require a license. For information about licensing, contact the STScI Business Office:

DSS FAQ

Frequently Asked Questions

Data

- What type of data are supported by MAST?
- How do I search MAST?
- How can I retrieve MAST data?

Documentation

- Are there manuals available for the MAST Archives?
- Is there a MAST Newsletter?

More FAQ

- Can I find FAQ's for individual missions?

User Support

- What level of support is provided for the various missions?

Data

- ***What type of data are supported by MAST?***
  The Multimission Archive at STScI supports:
  - The Hubble Data Archive (HDA), which contains spectroscopic (1,100 - 11,000 Angstroms range; slitless spectroscopy up to 2.5 microns with NIC3) and imaging (1,150 - 25,000 Angstroms) data taken with Hubble Space Telescope. As of August 1998, the HDA contains over 5.2 Tbytes of science and engineering data, for a total of approximately 150,000 science exposures.
  - The Far Ultraviolet Exporer (FUSE) covers the 905-1187 Å spectral region. This active mission contains high planetary resolution spectra of hot and cool stars, AGNs, supernova remnants, planetary nebulae, solar system objects and the interstellar medium.
  - The International Ultraviolet Explorer (IUE) Final Archive, which contains over 104,000 spectra of approximately 10,000 individual astronomical sources (covering the 1,200 - 3,350 Angstroms range).
  - The Extreme Ultraviolet Explorer (EUVE) Archive, which at present contains spectroscopic observations (in the 70 - 760 Angstroms range) of about 300 sources, mostly Galactic.
  - The Hopkins Ultraviolet Telescope (HUT) Archive, which contains 106 spectrophotometric observations of 77 targets were obtained in the far-UV (i.e., 912-1850 Å) at a resolution of ~3 Å. These were obtained during the first ASTRO mission. An additional 385 observations of 265 targets were obtained during the ASTRO-2 missions.
  - The Ultraviolet Imaging Telescope (UIT) Archive, which contains 1,579 images of 259 targets (covering the 1,200 - 3,300 Å range) obtained by UIT as part of the ASTRO-1 and ASTRO-2 missions.
  - The Wisconsin Ultraviolet Photopolarimeter Experiment (WUPPE) Archive, which contains 467 observations of 169 objects. WUPPE obtained simultaneous spectral and polarization measurements from 1400 to 3300 Å during the ASTRO-1 and ASTRO-2 missions.
  - The Copernicus Archive, which includes far- (900 - 1,560 Angstroms) and near- (1,650 - 3,150 Angstroms) ultraviolet spectra of 551 objects, primarily bright stars.
  - The Berkeley Extreme and Far-UV Spectrometer (BEFS), flew on the Orbiting and Retrievable Far and Extreme Ultraviolet Spectrograph (ORFEUS)-SPAS I and II space shuttle missions in 1993 and 1996, returning high-resolution (/3000) FUV spectra (900-1200 Å) of 75 astrophysical objects from the first flight and more than 100 from the second. EUV spectra (400-900 Å) were obtained for a subset of these targets.
  - The The Interstellar Medium Absorption Profile Spectrograph (IMAPS) obtained high resolution (R=75,000 for IMAPS-1) objective-grating echelle spectra of hot stars, over the spectral region 950-1150 Å. The IMAPS archive currently contains roughly 600 spectral images of 10 hot stars from the first shuttle flight. Once the proprietary period ends for the second IMAPS mission, the archive will include an additional 3,900 spectral images of 29 stars
  - The Tübingen Ultraviolet Echelle Spectrometer (TUES) flew on the Orbiting and Retrievable Far and Extreme Ultraviolet Spectrograph (ORFEUS)-SPAS II space shuttle mission in 1996, returning spectra in the 900 Å to 1400 Å wavelength range. The instrument was designed to achieve a spectral resolution of $\lambda/\Delta\ \lambda$=10000 when used with an entrance aperture of 10" diameter. During the 17.7 day flight, TUES returned 239 spectra of 62 targets.
  - The Digitized Sky Survey (DSS). The Catalogs and Surveys Branch of the STScI has been digitizing the photographic Sky Survey plates from the Palomar and UK Schmidt telescopes in order to support HST operations and provide a service to the astronomical community. Archive users can easily retrieve image data for any part of the sky.
  - The The Guide Star Catalog I (GSC I) is an all-sky optical catalog of positions and magnitudes of approximately 19 million stars and other objects in the 6th to 15th magnitude range. The GSC II is an all-sky catalog of approximately 2 billion stars and galaxies containing positions, magnitudes, colors and proper motions complete to a minimum of V =18.
  - The Sloan Digital Sky Survey (SDSS) is using a dedicated 2.5 m telescope and a large format CCD camera to obtain images of over 10,000 square degrees of high Galactic latitude sky in five broad bands (u', g', r', i' and z', centered at 3540, 4770, 6230, 7630, and 9130 Å, respectively). The first data release, planned for June 2001, includes: imaging data containing a searchable catalog, images in several formats (FITS and JPEG), and spectra in both FITS format and GIF spectra with line identifications. This first public data release will contain over 500 square degrees of sky.
  - The Faint Images of the Radio Sky at Twenty-centimeters (FIRST) Archive. The FIRST project is designed to produce a radio survey at 20 cm (1.4 GHz) of over 10,000 square degrees down to a flux of 1 mJy. MAST provides access to the radio images and the source catalog, which currently includes about 437,000 entries.
  - The ROSAT, the RÖntgen SATellite, was an X-ray observatory developed through a cooperative program between Germany, the United States, and the United Kingdom. ROSAT data is maintained and archived at HEASARC. Except for the search and acknowledgments pages, all images and linked pages are provided by HEASARC.

- ***How do I search MAST?***
  Every single archive can be searched using its search page. Links to the Web pages of the various archives included in MAST are available from the MAST main page. Moreover, for users wanting to search more than one archive at the same time, two interfaces are provided:
  - From the MAST main page one can conduct a quick search by typing the name of a target to see if any of the MAST supported archives have observations of this target.
  - The MAST Cross Correlation page provides a facility to allow the user to cross-correlate lists of positions with data in our archives. You can compile lists externally or use one of our online catalogs.

- ***How can I retrieve MAST data?***
  All MAST data can be retrieved from the appropriate Web pages. HST, FIRST, and DSS data can also be retrieved using StarView.

Documentation

- ***Are there manuals available for the MAST Archives?***
  Yes. You can get them here:
  - The HDA Manual
  - IUE Reduction/Analysis Documentation
  - IUE Instrumentation/Operations Documentation
  - IUE Project Publications
  - EUVE Project Publications
  - Copernicus Reduction/Analysis Documentation
  - Copernicus Instrumentation and Operations Documentation
  - UIT Publications
  - WUPPE Instrumentation and Operations Documentation
  - HUT Instrumentation and Operations Documentation

- ***Is there a MAST Newsletter?***
  Yes. It is sent out electronically to a distribution list. You can also read it on-line. If you would like to subscribe to the mailing list, please send e-mail to archive_news-request@stsci.edu and put the single word SUBSCRIBE in the BODY of the message.

More FAQ

- ***Can I find FAQ's for individual missions?***
  More FAQ for the single archives are available on the following pages:
  - HDA FAQ Page
  - IUE FAQ Page
  - Copernicus FAQ Page
  - EUVE FAQ Page
  - FUSE FAQ Page
  - BEFS FAQ Page
  - TUES FAQ Page
  - GSC FAQ Page
  - HUT FAQ Page
  - UIT FAQ Page
  - WUPPE FAQ Page
  - DSS FAQ Page

User Support

- ***What level of support is provided for the various missions?***
  Assistance is available for users of the various data included in MAST, although at different levels. Namely:
  - Full support for HST data analysis.
  - Full support for IUE data analysis (except for enhancement of post-pipeline data products).
  - Moderate support for EUVE data analysis.
  - Limited support for DSS, Copernicus, UIT, HUT, and WUPPE data analysis.

  Questions about HST data analysis should be sent to help@stsci.edu. Questions about IUE, EUVE, Copernicus, and UIT data analysis should be sent to archive@stsci.edu.

OAO-3 "Copernicus" High Resolution Spectral Atlases

During the *Copernicus* mission several stars were observed intensively with the high-resolution spectrometers to obtain as complete wavelength coverage as possible. Ultraviolet high resolution spectral atlases were constructed for six stars: Alpha CMa (Sirius), Alpha Lyr (Vega), Beta Ori (Rigel), Gamma Peg, Iota Her, and Tau Sco.

The atlas data were delivered to GSFC by the Copernicus Project at Princeton University in the early 1980s. The data are now available in FITS binary table format and can be selected from the following table. Each star also has a corresponding journal article describing the details of the extraction and analysis, including identification of spectral features. Summary information on the atlas contents and file descriptions are included on the pages for each atlas.

Star	V	Sp Type	Wavelength (Å)	Resol (Å)	Reference
Alpha CMa	-1.46	A1 Vm	1650-3170	0.10	Rogerson, *Ap.J. Supp*, 63, 369, 1987
Alpha Lyr	0.03	A0 Va	2000-3185	0.10	Rogerson, *Ap.J. Supp*, 71, 1011, 1989
Beta Ori	0.16	B8 Ia	999-1420 1420-1560	0.05 0.10	Rogerson & Upson, *Ap.J. Supp*, 49, 353, 1982
Gamma Peg	2.82	B2 IV	967-1430 1430-1500	0.05 0.10	Rogerson, *Ap.J. Supp*, 57, 751, 1985
Iota Her	3.80	B3 IV	999-1420 1420-1470	0.05 0.10	Upson & Rogerson, *Ap.J. Supp*, 42, 175, 1980
Tau Sco	2.84	B0 V	949-1420 1420-1560	0.05 0.10	Rogerson & Upson, *Ap.J. Supp*, 35, 37, 1977

The files may be read with any FITS reader that supports the binary table format. The IUEDAC procedure IFITSRD is a generic IDL based FITS reader which can be used to read these files.

EUVE Atlas of Stars

This page takes you to a table containing EUVE (Extreme Ultraviolet Explorer Data) spectra of 94 stars selected by Craig et al. (1997). The list is roughly representative of the sample of stars by the EUVE project during its lifetime (1992-January 2001). These spectra were taken whenever possible with all the three bandpasses, short- (SW; 70-190 Å), medium- (MW; 140-380 Å), and long-wavelength (LW; 280-760 Å). The spectral resolutions for these cameras are 0.5, 1, and 2 Å, respectively.

The stars are organized in a table by spectral type and by subcategories within each type. A user may click on the 'ps' link to browse a multi-panel image or one of the three bandpass links to download the data in compressed FITS format. The x-axis is in wavelength units, while the y-axis is in units of photons/cm^2/s/Å).

It is important to point out that the spectra in this atlas were only the best available at the time of the compilation. In some cases longer exposures were made after the atlas was constructed (late in the mission lifetime) and are available in the HEASARC/MAST archives.

Available Data

FOS Composite Quasar Spectrum

This is a mean quasar spectrum, between 350 and 3000 Å, constructed from 2 84 FOS obser vations of 101 quasars with redshifts z > 0.33, as described in **Zheng, W., et al. 1997 ApJ,475,469**, from the 1 Feb issue of *The Astrophysical Journal*. This reduced archival data is made available courtesy of Wei Zheng .

The spectrum is available as a flat ASCII file:

- **Uncompressed** (409.96 kbytes)
- **Unix compressed** (93.087 kbytes)
- **gzip compressed** (78.277 kbytes)

(Your browser should attempt to save the above files to disk, rather than displa ying them.)

The table columns are:

- **Rest wavelength (Å)**
- **Relative flux F(λ)**
- **Error**
- **RMS**

HST/GHRS Spectral Atlas of the O9 V Star 10 Lacertae

This page brings you to an ultraviolet atlas of 10 Lacertae constructed by members of the HST Goddard High Resolution Spectrograph (GHRS) scientific development and calibration teams. The star 10 Lac was chosen because it is unique as a bright O (O9V) star exhibiting a very sharp-lined spectrum. As a member of the Lacerta OB1 association, the star is known to have a distance of about 600 pc.

The atlas consists of a number of plots of relative flux versus wavelength over the range 1181 -- 1777 Å. The data were recorded by 4:1 substepping the G160M (medium resolution) grating over an angle corresponding to one pixel at the detector. Each pixel corresponds to a spectral resolution element of about 15 km/s. Fluxes of "continuum pixels" range from 32,000 to 100,000 photon counts across the total spectral range, resulting in a signal-to-noise ratio in excess of 100. The data were recorded over a total time of about 5 hours on 6 November, 1992 through the small science aperture. Note that these observations were done before the installation of the COSTAR corrective optic element. Full details of these observations are given by Brandt et al. (1998).

Taking into account the signal to noise, wavelength range, and the wealth of unblended sharp lines, this is probably the most comprehensive ultraviolet spectral atlas of a hot star published to date. Wavelength identifications were obtained with the aid of a spectral line synthesis codes and model atmosphere data. This has permitted some line blends to be designated. Identifications are given in the atlas for 45 interstellar lines of 17 ions. Stellar wind lines are evident in the form of asymmetric C IV (1548, 1551 Å) and N V (1239, 1243 Å) absorption lines as well as nearly symmetric absorption lines of strong lines of He II, Si IV, and N IV. The atlas is dominated by the presence of over 700 absorption lines of six ionization levels of 16 chemical elements. The interstellar line list and the full list of photospheric lines is given in the accompanying two tables. The "Data" consist of two-column ascii files listing the wavelengths (Ångstroms) and flux (10^9 ergs cm^2/s/Å). "ID" list both measured and laboratory wavelengths; the sources for the latter are given in the Brandt et al. paper.

Available Data

HST/GHRS Observations of the HgMn star chi Lupi

A major, eight-year investigation of the extraordinarily detailed ultraviolet spectrum of the sharp-lined, non-magnetic, main-sequence chemically peculiar star chi Lupi (B9.5pHgMn + A2Vm) was undertaken as a GHRS GTO team project. The UV observations are comprised of 345 Å of the spectrum acquired with the Goddard High Resolution Spectrograph on board the *HST*, at an average resolution of 0.023 Å. The major results of this program are summarized in Leckrone et al. (1999), and the complete set of echelle spectrograms is presented as an atlas in Brandt et al. (1999).

We present here an online version of our reduced data, as well as the synthetic spectra and line identification lists used to produce the figures in Brandt et al. (1999). We anticipate that this atlas will be a useful resource for both astrophysicists and atomic physicists and will serve as a roadmap for future UV spectroscopy of late-B and early-A stars.

Available Data

Related Publications

HST/GHRS Chromospheric line Atlas for Procyon

This page brings you to a short series of ultraviolet spectra of chromospheric lines of Procyon (F5 IV-V) constructed and published by Dr. Brian Wood and colleagues at the University of Colorado (see Wood et al. (1996). MAST is grateful to these investigators for providing their data of a chromospheric spectrum of a near-solar type star.

The F5 IV star Procyon (alpha CMi = HD61421) was chosen it is a nearby star with prominent chromospheric emission lines in its spectrum. These lines appear to be broadened by nonthermal mechanisms and are formed over a range of layers in the chromosphere. Therefore, they exhibit similarities to chromospheric lines in the solar spectrum.

The Wood et al. atlas consists of plots of absolute flux for seven wavelength bands ranging from Si III, Lyman-alpha, and N V lines near 1200 Å to the Mg H/K lines near 2800 Å. The data shortward of 2000 Å were recorded through the Large Science Aperture (LSA) by 4:1 substepping the G160M or G200 (medium resolution) gratings, giving a resolution of 17,000 to 21,000. Longward of 2500 Å the small science aperture (SSA) was used, and substepping was again done, this time with the EB-20 or EB-22 echelle gratings, giving a resolution of about 75,000.

The data given in the table and figures are very similar but not precisely equivalent to those published. The new data provided by Dr. Wood differ from those published in that: (1) a more recent flux calibration has been employed, (2) wavelengths are given "old style" (in-air wavelengths longward of 2000 Å), (3) annotations in the figures give the in-air laboratory wavelengths of the chromospheric lines, (4) multiple lines of an ion on any one plot arise from the same multiplet, (5) very weak lines identified in the paper are omitted from our rendition of the plots. In addition, note that the Wood et al. paper details the small redshifts of these features.

Available Data

HST/GHRS Spectral Atlas of the M2 Iab Star Alpha Orionis

This page brings you to an ultraviolet atlas of Alpha Orionis (Betelgeuse) constructed by members of the HST Goddard High Resolution Spectrograph (GHRS) scientific development and calibration teams. This star was chosen because of extensive observations of it from ground-based spectrographs, photometers, and interferometers in the optical and IR spectral regions and because of the time coverage of its variations from ground sites and the IUE satellite by many observers.

The spectral data were recorded on 1992 Septmber 24 using the GHRS Small Science Aperture (SSA). (Note that these observations were done before the installation of the COSTAR corrective optic element.) The atlas consists of a number of plots of relative flux versus wavelength over the range 1979 -- 3300 Å. The data were recorded through the Large Science Aperture (LSA) by 4:1 substepping the G270M (medium resolution) grating over an angle corresponding to one pixel at the detector. The pixel-to-pixel sampling decreases with increasing wavelength from 3.7 to 2.0 km/s, or about 1/4 of a resolution element. The signal to noise in "continuum pixels" varies from 3 near 2000 Ångstroms to about 30 at 3000 Ångstroms; in the emission lines the SNR is somewhat higher. Full details of these observations are given by Brandt et al. (1995).

Taking into account the signal to noise, wavelength range, and the wealth of unblended sharp lines, this is possibly the most comprehensive ultraviolet spectral atlas of a cool star published to date. Wavelength identifications were obtained primarily from lines already observed in this star and other luminous red stars by the IUE. Laboratory measurements were taken from R. L. Kelly (J. Phys. & Chem Ref. Data, 16, Suppl. No. 1, 1987).

The "Data" consist of two-column ascii files listing the wavelengths (Ångstroms) and flux (10^9 ergs cm^2/s/Å); the column headers must be stripped before being numbers are read. The identifier "ID" lists both measured and laboratory wavelengths; the sources for the latter are given in the Brandt et al. paper. Note that some fluxes in the original data are negative; these have been set artificially to zero.

Available Data

HST/Time Series of gamma Cas GHRS observations

This page brings you to an ultraviolet grayscale timeseries of difference spectra for gamma Cas in the neighborhood of the SiIV resonance lines. This is a unique kind of data set for the GHRS.

The spectral data were recorded for over 21 hours while gamma Cas was in HST's "continuous viewing zone" on 1996 March 14-15 using the GHRS 2" Large Science Aperture (LSA). This mode of observing permitted observations to be made continuously except for a few minutes of wavelength recalibration at the end of each orbit and except for interruptions of the South Atlantic Anomaly, which became non-negligible toward the end of the observing sequence. The observations covered 1045 out of a total of 1280 minutes. The data were obtained at a cadence of one spectrum per second in the ACCUM mode (8100 counts per second per pixel) with the G160M grating and were later rebinned to 1 spectrum per minute. The ACCUM mode permitted only a modest resolution (30 km/s) but provided the ability to integrate fluxes unobstructed by an aperture and construct a pseudo-continuum light curve from "non-line pixels." The spectral range covers approximately 1382--1417 Ångstroms.

Several instrumental effects had to be removed to obtain the final spectra. These effects included included fixed pattern noise artifacts from the detector, differential spacecraft velocities, and shifts of the spectrum in both detector coordinates caused by changes in the Geomagnetic field (so-called "GIMP") as the spacecraft traced its orbit. The removal of the velocity effect gives a slight residual wavy appearance to sharp features in the grayscale plot. Finally, photometric variations in a 140 pixels to the red of the Si IV line complex were removed and are presented as a separate data file. Finally, a maximum-spectrum template was obtained from the spectra by submtracting the maximum flux at each pixel from each spectrum of the time series. The data shown are from difference spectra from that template in units of continuum = 1. Full details of the data reductions and of the continuum light curve are given in Smith, Robinson, and Hatzes (1998).

The spectra were taken as part of a simultaneous campaign with the RXTE satellite and contemporaneously with IUE and optical observations two months earlier. A full analysis of the details of the X-ray characteristics are given in Smith, Robinson, and Corbet (1998). The analysis of the quasi-continuum light curve obtained from these and wavelength-integrated IUE data are discussed in terms of occulting magnetic clouds by Smith, Robinson, and Hatzes (1998). The analysis of the variations of the photospheric Si IV lines, the blue-to-red moving (striated) features, and many other faint features away from the Si IV complex is published by Smith and Robinson (1999). An analysis of the Si IV DAC features in the context of X-ray illumination is given by Cranmer, Smith, and Robinson (2000, in preparation).

The "Available Data" consist of spectral and photometric data files. The photometric file lists time from start in minutes and the flux normalized to unity for (normalized for the first two orbits) is a UV pseudo-continuum light curve The spectral files consist of two-column ascii files listing the wavelengths (Ångstroms) and flux in continuum units. The one line identifying header must be stripped before numbers are read in the wavelength and flux files. Postscript and files of the grayscales are scaled in intensity to bring out the global development of the dominant, Discrete Absorption Features of Si IV and also the faint absorptions and striations ("migrating subfeatures") that are ubiquitous in this region of the spectrum. These figures show wavelength from left to right and time in minutes from bottom to top.

Suggested Guidelines for Authors of Prepared Science Products

The MAST Prepared Science Products site provides a user with on-line information that can be browsed or downloaded (e.g., preview images, data files) by users. In general, these science products should be data that have been processed and interpreted to a degree considerably beyond that obtained from pipeline processing, i.e. modifications to the pipeline data product that are critical to the published scientific result. Common examples are spectral atlases, greyscale spectral images of temporal activity of an object, and image atlases. Datasets of related images and spectra of objects are also encouraged. Tables of extracted parameters (e.g., equivalent widths, radial velocities) would not in themselves comprise a complete Prepared Science Product. We have introduced a separate subcategory for prepared science products that are catalogs with links to the published data.

MAST reserves the right to select which datasets will be posted in this site. In some cases MAST will agree to point to an external site that already adheres to its standards and protocols. Authors interested in contributing data to the MAST Prepared Science Products site should contact the address given at the bottom of this page.

Here are some guidelines that MAST has found useful to aid users interested in offering data for this site:

1. the prepared science product should be published in a refereed journal or have a demonstrable record of use,
2. the data may be prepared either in the form of standard FITS files, or (spectra only) ASCII tables. If possible, the FITS headers should provide information pertinent to the observation (date, exposure time, instrument). Other data products (preview images, documentation) do not have to be limited to these formats,
3. the home page should consist of a prolog or introduction to the use of the prepared science product. This page should link clearly to a catalog or data listing. This page should give a simple explanation of what instrument was used to obtain the data, the purpose of the observations, detailed information on data processing (especially non-standard procedures), and any other useful information to orient the user (the user should be considered to be a professional astronomer from any of many diverse subcommunities),
4. clear links (preferably not embedded in text) should be provided for easy navigation,
5. data should be listed in a catalog or table referring to a common object (or sky region),
6. preview images should be put in a standard imaging format, such as gif, ps, jpeg, etc.,
7. each image should refer to a separate object or sky region (e.g. no spectral montages of different objects having similar physical properties),
8. A copyright statement supplied by MAST should be displayed at the end of the home page,
9. No extra data processing should be required from MAST staff.

MAST Prepared Science Products

The following is a listing of sites of highly processed datasets from missions supported by MAST. These are datasets consisting of atlases, images, and/or the data themselves which have been placed on the web either as final data products or as appendices referenced in recent published papers. These data are in the public domain and/or will soon be published. The datasets are organized by type of observation (survey, individual objects, time series) and will include a growing number of catalogs with links to the data and in some cases spectra and/or images.

About the IUEDAC

IUEDAC User's Guide

The latest **IUEDAC User's Guide** was updated on February 5th, 1998, and is now available online. The changes primarily include more information on working with various file formats and analyzing NEWSIPS data. (Note the one major change since the User's guide was updated was that the program COADD is now compatible with NEWSIPS high dispersion files.)

The User's Guide is also available for downloading in either **Postscript (guide.ps)** , **LaTeX (guide.tex)** , or **PDF (guide.pdf)** format. A limited number of hardcopies are available on request.

IUEDAC IDL Software Libraries

Latest News: Chronological listing of the most recent changes to the IUEDAC software libraries.

The IUEDAC software libraries below (except the windows NT file which was updated March 16th, 2000), were last updated: 30 June 1999.

- **Macintosh**
- **Ultrix and DEC Unix**
- **Sun Unix**. May also be used for Linux (although this platform is not officially supported).
- **Vax VMS**. Please see this note concerning record attributes and recent IDL changes.
- **Windows**. Use win31_rdaf.exe for windows 3.1 systems, winNT_rdaf.zip for others.

Individual Procedures: Allows individual programs to be displayed or downloaded.
Beta software: Files for all platforms created or modified since the last library set was created.

IUEDAC Software Documentation

The primary source for documentation on individual programs is the procedure prologs. The **IUEDAC Software Documentation Search** page allows this information to be displayed for specific procedures. Since the IUEDAC prologs uses a standard format, searches can also be made of subheadings by specifying the particular keyword. For example, the "modification history" can be displayed to see when the last changes were made, or a summary of the progam or programs (wildcards are allowed) can be displayed by selecting the keyword "purpose".

Y2K Testing

The **Y2K-Testing** page describes a study to determine which if any of the IUEDAC programs may have problems in the year 2000. The study resulted in several program modifications, all of which have now been incorporated into the IUEDAC libraries. The compressed libraries are available for download from the **iuedac software** directory in the anonymous ftp area.

NOST 100-2.0

NASA/Science Office of Standards and Technology
Code 633.2
NASA Goddard Space Flight Center
Greenbelt MD 20771
USA

The NASA/Science Office of Standards and Technology (NOST) of the National Space Science Data Center (NSSDC) of the National Aeronautics and Space Administration (NASA) has been established to serve the space science communities in evolving cost effective, interoperable data systems. The NOST performs a number of functions designed to facilitate the recognition, development, adoption, and use of standards by the space science communities.

Approval of a NOST standard requires verification by the NOST that the following requirements have been met: consensus of the Technical Panel, proper adjudication of the comments received from the targeted space and Earth science community, and conformance to the accreditation process.

A NOST standard represents the consensus of the Technical Panel convened by the NOST\@. Consensus is established when the NOST Accreditation Panel determines that substantial agreement has been reached by the Technical Panel. However, consensus does not necessarily imply that all members were in full agreement with every item in the standard. NOST standards are not binding as published; however, they may serve as a basis for mandatory standards when adopted by NASA or other organizations.

A NOST standard may be revised at any time, depending on developments in the areas covered by the standard. Also, within five years from the date of its issuance, this standard will be reviewed by the NOST to determine whether it should 1) remain in effect without change, 2) be changed to reflect the impact of new technologies or new requirements, or 3) be retired or canceled.

The Technical Panel that developed this version of the standard consisted of the following members:

- **Robert J. Hanisch**, Chair, Space Telescope Science Institute
- **William D. Pence**, Secretary, NASA Goddard Space Flight Center
- **Barry M. Schlesinger**, Past Secretary, Raytheon STX
- **Allen Farris** , Space Telescope Science Institute
- **Eric W. Greisen** , National Radio Astronomy Observatory
- **Peter J. Teuben** , University of Maryland
- **Randall W. Thompson**, Computer Sciences Corporation
- **Archibald Warnock**, A/WWW Enterprises

Members of the previous Technical Panels also included:

- **Lee E. Brotzman**, Hughes STX
- **Edward Kemper**, Hughes STX
- **Michael E. Van Steenberg**, NASA Goddard Space Flight Center
- **Wayne H. Warren Jr.**, Hughes STX
- **Richard A. White**, NASA Goddard Space Flight Center

This standard is published and maintained by the NOST. Send comments and orders for NOST documents to:

MAST Data Format Guidelines

Introduction

This document describes recommendations for formatting data sets using the **Flexible Image Transport System** (i.e. **FITS**) format for inclusion in the Multi-mission Archive at the Space Telescope Science Institute (MAST). It assumes the reader is already somewhat familiar with FITS format. The terminology used is that defined in the **NOST FITS Draft Standard** (Copies of the FITS standard can be downloaded from the **FITS Support Office.**)

Choosing the Appropriate FITS Format

FITS has evolved significantly during the past 5 years. As a result, there is usually more than one way to store the same information within a FITS file. Each mission must decide which FITS format is most appropriate for their own data sets. This may be influenced by the data analysis software currently in place at the users institutions, since not all FITS readers support all the currently available FITS formats. A summary of the FITS formats used by the missions currently supported by MAST can be found in the **FITS File Formats** table. The table shows that projects have used a variety of FITS formats for archiving data, including all the approved FITS extensions. The one FITS format not represented is the **"Random Groups Structure"**. Although this format is defined in the NOST FITS Draft Standard document and used for radio interferometry data, it has become a deprecated standard and is not recommended for MAST archival data sets.

The **HEASARC** FITS Working Group (HFWG) has adopted a set of **FITS file Recommendations** for the high-energy astrophysics community. The HEASARC documents describe detailed recommendations regarding: the use of specific project-defined keywords, recommended formats for particular types of data, the naming of table columns, and the use of particular physical units. Although aimed primarily at the high-energy astrophysics community, the recommendations should be useful for other projects as well.

Similiarly, the **AXAF Science Center** (ASC) has compiled the **ASC FITS File Designers Guide** which details the FITS conventions adopted by the AXAF project for its archival data sets. (Note the AXAF guidelines comply with the HFWG guidelines.)

FITS keyword conventions have also been adopted at the Solar Data Analysis Center (SDAC) at Goddard Space Flight Center for several solar missions.

Besides the **FITS Support Office** at Goddard Space Flight Center, another source for FITS documents, sample FITS files, and links to other FITS-related sites, is the **FITS Archive at NRAO** .

Spectral Data

In general, we suggest storing spectral data (i.e., data sets composed of one or more vectors) using **binary table extensions**. It is also possible to store vectors in a non-homogeneous primary array, (e.g., having a row of wavelengths followed by a row of fluxes, etc.) however it is usually more difficult to interpret the resulting data set. Some data analysis systems have however adopted conventions for handling these files (e.g., IRAF).

A binary table containing vector fields seems the most logical way to store this type of data although some FITS readers may not be able to read this format. Hopefully this will change in the near future. With vector fields, one row in the binary table could contain all the data for one spectrum (e.g., a vector of wavelengths, followed by a vector of fluxes, etc.). Additional spectra could be stored in the same manner in the following rows (assuming the vectors are of the same length and format). Currently, a more readable but less flexible format would be to store the data in scalar fields so that each row of the table contains all the data for one wavelength. This implies however that the table could not be used for storing multiple (e.g., echelle) spectra. FITS files could however contain multiple binary tables.

If multiple spectra are to be stored which have vectors of variable length, the project must decide between the following format options:

- pad the vectors with zeroes to a fixed length and store as vector fields in one table,
- use scalar fields and one spectrum per table with one wavelength/flux value per row in the table,
- use the **not-yet-approved** variable-length array facility described in the original binary table extension proposal and store all spectra in one table. (The Copernicus raw data sets are an example of this format.)

Although non-linear wavelength values must usually be stored as individual values, linear wavelengths can be stored as FITS keywords (i.e., a starting wavelength and a wavelength increment), or, if multiple spectra are to be stored within each binary table (e.g., one table row per spectra), the starting wavelength and wavelength increment can be stored as scalar data fields within the table. Note the IAU now approves the use of vacuum wavelengths above 2000 Angstroms, so UV data no longer need to contend with the vacuum-to-air correction which causes a non-linearity at 2000 Angstroms.

As mentioned before, not all processing systems support vector fields. Earlier versions of IRAF for example, do not support this format. Although the **variable-length array facility** is not yet an approved FITS standard, the use of vector fields in binary tables has been an approved format since 1994, so hopefully more FITS readers will support this format in the future. Projects must decide which format would best serve their user community.

Image Data

Image or multi-dimensional data can be stored as a **primary array**. This is the most basic FITS format and should be readable by most if not all FITS readers. Technically the Binary table extension can also be used to store **multi-dimensional arrays**, however most FITS viewers currently require primary array FITS files. Image data can also be scaled (using the BSCALE and BZERO keywords) to allow data to be stored as integers rather than (larger) floating point values, however unless disk space is an issue, it is preferable to store the data unscaled.

FITS extensions can be added for either additional image or spectral data. We recommend **image extensions** for additional image data, **binary tables** for storing mixtures of ASCII and binary data, and **ASCII tables** for purely ASCII data. Note ASCII tables are particularly useful for storing "catalog-type" information.

Keywords

Besides the **required FITS keywords**, the project-defined keywords should be sufficient to properly describe the included data. This information is also useful when included as a separate project catalog (see MAST Guidelines for Archiving Astrophysical Data). For processed data, it is useful to store the processing history using **FITS commentary keywords** (i.e., using the HISTORY, COMMENT, or blank keywords). It is also strongly recommended that the project-defined file name be stored using the FITS FILENAME keyword.

Data to be archived within MAST will be checked for proper syntax using various FITS verification programs. The reserved FITS keywords must follow the standard FITS conventions or they will be modified to conform. (Surprisingly, we have found several errors in the DATE and DATE-OBS keyword values.) Project-specific keywords will generally not be modified. It is suggested that the keyword comment fields be used to help define these keywords.

Keyword Inheritance

There has been some discussion lately about whether information contained in the primary header should be relevant to data stored in the extensions. In other words, should the extensions "inherit" the keywords contained in the primary header. Unfortunately, the FITS community has not reached a consensus on how this should be handled. Some feel the extensions should be self-contained and not linked in any way to the primary header information, while others assume the primary header information should be considered global and apply equally to all data in the file. Adding to the problem is the fact that numerous FITS files were created and archived before the issue was ever raised.

One suggestion has been to include the keyword INHERIT (with a value of either T (true) or F (false)) in the extension headers to indicate whether the primary header keywords apply to each particular extension. This would help avoid the ambiguity, however the INHERIT keyword has not been officially reserved for this purpose. This convention however has been adopted by the HST project and is described in the STScI User's Guide to the IRAF FITS kernel.

A survey of the existing (non-HST) MAST data sets found that inheritance was assumed in **all** FITS files containing extensions. In other words, **all** the MAST archived FITS files assume that project-defined keywords in the primary header apply to all the extensions contained within the file. In general, the convention has been to store all the observation information in the primary header, and store only a minimal number of FITS keywords in the extension headers. It may be the case however, that older missions tended to use simpler file formatsi.

It is therefore difficult to give future missions a recommendation regarding keyword inheritance. The choices are basically:

- assume no inheritance and duplicate all neccessary keywords in all extensions,
- assume keywords in the primary header are global and apply to all extensions, or
- use the HST convention of adding the keyword INHERIT to the extension headers indicating whether keyword inheritance should apply.

Perhaps the FITS community will adopt a convention for keyword inheritance in the near future which could apply to all future FITS files.

Units

Another recently discussed issue has been the use of standard units for data stored in FITS format. The current FITS standard states units "... should conform with the recommendations in the IAU style manual". The problem however is that most UV spectral data archived in MAST use Angstroms for wavelengths and ergs/cm2/s/A for absolute fluxes, both of which are listed in the IAU style manual. as "obsolete units". As with the "keyword inheritance" issue, there is not yet a consensus among the FITS community regarding the use of standard units and it is therefore difficult to make a recommendation for future missions.

Coordinate Keywords

It is recommended that data sets include the target coordinates using Right Ascension and Declination specified in decimal degrees. There is currently no consensus as to the keyword names to use, but this may be at least partly dictated by the spacecraft instrumentation. Some of the currently used keywords are shown in the FITS coordinates table.

File Naming Conventions

The only suggestions made for data set names are the following:

1. the name should be sufficient to uniquely identify each data set,
2. file names should be case-insensitive,
3. names should be no longer than necessary.

Historically file names following the ISO 9660 standard had a maximum of 8 characters for the name and 3 characters for the extension. This convention meant that files could be stored on DOS or Windows 3.1 16-bit computer systems without truncating the file name. Now that 32-bit computers are more common, this naming convention is less important and longer file names are common. However consider that many users may need to ftp files between systems, and have to manually type in the file names.

Flexible Image Transport System (FITS)

The astronomical community has adopted the **Flexible Image Transport System** (i.e. **FITS**) format as the default standard for the exchange of data between institutions. The FITS file format is platform independent, supported by many institutions, and endorsed by both NASA and the IAU. For these reasons FITS is the recommended file format for archiving data at STScI. A description of the MAST data format recommendations can be found in the **MAST Data Format Guidelines** document.

For the official description of the FITS format, see the **FITS Standard Document**.

The **FITS User's Guide** provides examples, infomation on the history of FITS as well as a thorough description of the format.

Acknowledgments

The MAST staff wishes to acknowledge the work that other groups and projects have done and allowed us to use. Thank you to:

- Canadian Astronomy Data Centre (CADC) for the HST preview images

- NASA's Goddard Space Flight Center (GSFC) Astrophysics Data Facility (ADF) staff for access to the IUE and UIT browse images, and copies of the IUE, UIT, WUPPE, and HUT datasets. ADF staff members provided background information and documentation about these datasets. Special thanks to the WISARD group for a copy of their UIT databases.

- GSFC's Laboratory for Astronomy and Solar Physics (LASP) IUE Project for the IUE Documentation, the IUEDAC web pages, the IUEDAC software package, and the initial copy of the database.

- EUVE Project for initial copy of the EUVE database and various web pages.

- WUPPE , UIT , and HUT projects for additional information, documentation, and data.

- High Energy Astrophysics Science Archive Research Center (HEASARC) for access to the on-line copies of the EUVE data

- Dr. George Sonneborn and other members of the GSFC LASP for the Copernicus data, database, and associated web pages.

We would also like to request that users acknowledge the use of data obtained from MAST in their publications. An example acknowledgment is shown below.

> "Some/all of the data presented in this paper were obtained from the Multimission Archive at the Space Telescope Science Institute (MAST). STScI is operated by the Association of Universities for Research in Astronomy, Inc., under NASA contract NAS5-26555. Support for MAST for non-HST data is provided by the NASA Office of Space Science via grant NAG5-7584 and by other grants and contracts."

Users wishing to use documents obtained from the MAST web site for other than personal use, should first contact the MAST staff at archive@stsci.edu regarding neccessary permissions and acknowledgements.

Archive Status & Staging Disk Capacity

Planned Archive Downtimes

These are scheduled downtimes which will affect access to the HST Archive. Note: Due to the nature of the archive systems, we cannot always report unscheduled downtimes.

```
Thu Mar 21 11:56:54 EST 2002

Searches may be unavailable for an hour starting at 1 PM EST
today, March 21st.

We apologize for the inconvenience.
```

Check on the status of your individual requests *here*.

Staging Disk Capacity

This is the most current capacity of the Archive host's (archive.stsci.edu) staging disk:

```
Fri Mar 22 07:20:15 EST 2002

Filesystem            kbytes    used   avail capacity  Mounted on
/dev/dsk/c4t124d0s6  846332414 388063019 449806071    47%    /stdatu/dads_stage
```

For Netscape-compatible browsers, this page will be refreshed every five minutes.

If the capacity is near 100%, then the staging disk is full, and HOST retrievals and retrivals submitted through the Web interface will fail. When that happens, you may either

- Wait until there is more space on the staging disk (every hour, files older than three days are swept from the staging disk), or
- you can select NET retrieval instead of HOST and have the data sent directly to your machine.

When the disk is full, and you have data on it you don't need, please let us know so we can delete it to make space for other retrievals.

HST Science Search Help

This page describes how to use the *new* **HST Science Search form** and describes the individual fields in that form.

> Features that are new in this release will be marked like this.

Use the HST Science Search form to search the HST Archive Catalog by object name, position, observation date, proposal ID, wavelength, and data type. You can also mark data for retrieval using this interface.

> This new interface can retrieve data either to the archive staging area or directly to the destination you specify, so you can now retrieve proprietary data (if you're priveleged to do so). To allow you to safely enter a destination username and password, we use the same security mechanism as many commercial sites.

Object Name

The name of the astronomical object you want to search for.

Resolver

The name resolver you want to use, if you want to get an object's coordinates. To resolve an object's name into its coordinates, enter the object name in the **Object Name** field, select either NED or SIMBAD for the resolver, and hit the **Resolve** button. The form will be redrawn with the object's right ascension and declination entered as defaults in the **RA** and **Dec** fields. Resolving an object name will *not* change any other choices made in the form.

> You don't *have* to hit the resolve button, though. If you enter an object name and select either SIMBAD or NED, and then hit the "Search" button, the script will get the coordinates before doing the search. A message will appear at the top of the results page showing you what coordinates were found for the object (or an error message if the name resolver didn't work for some reason).

We recommend that you use object-name resolution to find observations of fixed targets in the database. This is the most reliable way to look up observations, because the observer could have given the observation any name at all (for example, `NGC1976` instead of `M42`, or `PARALLEL-FIELD`). However, if you do know the name of the object, you can select HST Target Name, in which case, the object name will not be resolved into coordinates, but will be used as a search qualification in the database. (Remember when you do this to *not* press the **Resolve** button.)

The SIMBAD and NED object name resolvers can only resolve the names of fixed astronomical object; they cannot compute the positions of moving objects (planets, comets, etc.).

Resolve

When you press this button, the HST Science form will be redrawn with the coordinates of the object name entered into the RA and Dec fields.

RA,Dec

The Right Ascension and Declination around which you want to search. A number of formats are accepted for the RA and Dec. Here are some examples:

```
Decimal Degrees
    185.63325 29.8959861111111

Hours, minutes and Seconds
    12 22 31.98      29 53 45.55
    12h22m31.98s     29d53m45.55s
    12:22:31.98     +29:53:45.55
    12h22'31.98"     29d53'45.55"
    12h 22m 31.98s   29d 53m 45.55s
    12h 22' 31.98"   29d 53' 45.55"
    12h 22' 31.98"  -29d 53' 45.55"
    12h22'31".98    -29d53'45".55
    12h22m31s.98    -29o53m45s.55
    12h 22' 31".98  -29d 53' 45".55

Hours/Degrees and Minutes (no seconds)
    12 22     29 53
    12h22m   +29d53m
    12h22m    29d53m
    12:22m    29:53m
    12h22'    29d53'
    12h 22m   29d 53m
    12h 22'   29d 53'
    12h 22'  -29d 53'

The RA may be given in decimal degrees by
indicating a D or d after the degrees:
    12d 22m   29d 53m
```

Spacing is not important, as long as the value is unambiguous, and that you can delimit the hours/degrees, minutes, and (optional) seconds with letters, colons, spaces, or any character that's not a digit or a decimal point.

Note also that seconds of the form 31".98 or 31s.98 are accepted. This should make it easy to cut and paste values into these fields from electronic publications.

Radius

How far around the search position you would like to search, in arcminutes.

> This used to be the "radius" of a coordinate box, but we now compute the angular separation between each result dataset and the search center, so this really is a radius. (The results will be sorted on the angular separation by default.) So this really is a circular radius around the search position.
>
> One result is that you can do fancy stuff like searching for all observations between 2 and 8 arcminutes from the center of a galaxy (just give `2 .. 8` for the radius).

Equinox

The equinox of the RA and Dec you have entered, either B1950 or J2000. This only affects the input coordinates; the output coordinates will always be J2000.

> There's a selector for output coordinate types in the output options section, but it doesn't work yet.

Observation Date

The date of the observation. More specifically, the date and time, in GMT, on which the exposure was started. When specifying this date, you need to include a date and an optional time. The date can have any of the following formats (the month name can be spelled out or abbreviated to three letters; case is not significant):

```
Jul 15 1994
Jul 1994 15
15 Jul 1994
1994 Jul 15
1994 15 Jul
7/15/1994
7-15-1994
7.15.1994
```

If the day is omitted, the first day of the month is assumed. This means that a specification like "July 1994" will look for observations done on July 1 1994 00:00:00, *not* for observations done during July 1994. Note also that when entering a date with the month in numerical format, the American ordeing is used; i.e., the first number is the month.

If a time is omitted, then midnight (00:00:00) is assumed. Otherwise, you can specify a time in any of these formats:

```
14:30
14:30:20
14:30:20:999
14:30:20.9
4am
4 PM
04:30:20 AM
```

To search for observations before a given date, use <, and for observations after a given date, use >. For example,

```
> Jul 15 1994
< Jul 15 1994
```

You can use the .. operator to search on a range of dates:

```
Jul 1 1994 .. Aug 1 1995
```

This operator is inclusive on the first date and exclusive on the second.

Finally, you can search on a list of dates or date ranges. For example,

```
Jul 1 1994 .. Jul 3 1994,
Dec 1 1995 .. Dec 6 1995
```

will search for observations done within either one of these date ranges.

Exposure Time

The commanded exposure time in seconds. You can use operators or ranges in this field; for example,

```
< 100
> 1000.0
100 .. 1000
```

You can *exclude* a range of exposures using a comma:

```
< 100, > 1000
```

Observer/PI Last Name

The last name of the principal investigator of the observation. We sometimes refer to this person as the "observer".

Program ID

The HST proposal number under which the observation was executed. This can be a numeric ID or a comma-separated list of numeric IDs. Any characters other than digits, commas, and spaces will cause an error message to be displayed. For example, instead of searching for `GO-5916`, simply specify `5916`. Or to search for observations from either proposal 5410 or proposal 5916, specify `5410, 5916`. **Note: when using the prop_form search script, only one program id can be entered at a time.**

Obset ID

The observation set within the program. This is usually the same as the visit number, though in a small number of cases it will be different. The obset ID is used as the fourth and fifth letters of a dataset name. You can enter a comman separated list here. If necessary, obset IDs will be padded with leading zeroes to two characters.

Target Description

A short description of the target, supplied by the observer. like target names, these may not always be reliable- one observer's CLUSTER OF GALAXIES may be another's ELLIPTICAL- but they are generally better than nothing (especially where solar system objects are concerned; planet, asteroid, and comet names are more likely to be spelled out in the target description than in the target name).

Every morning, we generate a list of all the target descriptions currently in use. This list is linked back to the HST Science Search page, so you can read through this list (or search it with your browser's find capability) and find datasets matching the description.

Dataset Name

The dataset name is the unique identifier for an HST observation. (For NICMOS and STIS, it can also represent an association of exposures.) This value can be wildcarded using a *. *When you specify a dataset name, any instrument or wavelength specification will be ignored.*

Observation Band

Use this selector to decide how you want to use wavelengths in your search. The selector has three settings:

"Observation falls in this range"

For this setting, give a range of wavelengths (in Angstroms), separated by `..`; for example, `5000 .. 6000` indicates a range from 5000 to 6000 Angstroms. Observations will match this qualification when their central wavelength is within this range.

"Observation bandwidth contains this wavelength"

For this selection, you give a single wavlength in Angstroms; for example, `5000`. An observation will match this qualification when this wavelength falls within the bandwidth of the observation.

"Observation used these filters"

For this qualification, enter an HST filter name; for example, `F606W`. An observation will match this qualification if it used a filter by that name.

It's important to understand what we mean by "central wavelength" and "bandwidth" in the above discussion. For an image, these terms describe the throughput of the filter or filters used. For spectra, they describe the actual spectral range of the observation. (The exception to this rule is the FOC; for FOC spectra, "central wavelength" and "bandwidth" mean the same as for an image. This is because FOC spectra are done using an objective prism, and a spectral range is not calculated for them when they are archived.)

Also, notice that all wavelengths should be given in Angstroms.

Instruments Here you select which instruments you want data from. We've divided the instruments into Imagers, Spectrographs, and Other, but instruments that are (or were) capable of producing either images or spectra will appear in both places. These buttons will help you select *only* images or spectra from a particular instrument.

As a convenience, users with Javascript enabled in their browsers will see two little buttons here labelled `ALL` and `NONE`. These buttons will select or deselect all of the checkboxes in the section, so you don't have to go through hitting lots of checkboxes if you only want one instrument.

Imagers

In this section, select the kind of images you want to search for by selecting the instrument.

Spectrographs

In this section, select the kind of spectra you want to search for by selecting the instrument.

Notice that some instruments are capable of producing both images and spectra. In this case, the query will be properly built to search for the selected observation type for that instrument.

Other

Here you can select data from instruments that produce neither images nor spectra: the Fine Guidance Sensors (which produce astrometric, usually interferometric, data) and the High Speed Photometer (which produced photometric data). These are not checked by default.

Release date

Select the release date for the data, in GMT. See the observation date for the entry format. HST data has a nominal proprietary period of one year (though in special cases, this may be shortened or extended). The Release Date field gives the end of the dataset's proprietary period.

This used to be just a pair of radio buttons that let you specify only public or all data. Now it's a fully qualifiable date. By default it searches for everything released before today (i.e., public data only). If you're going to retrieve proprietary data, don't forget to delete this date.

Both public *and* proprietary datasets now have mark buttons. (Proprietary datasets will have an at symbol, @, next to the mark button, and on most browsers, the background for proprietary mark buttons will be yellow.) Properly authorized users will be able to retrieve proprietary data through the Web interface.

Archive Date

This is the date on which a dataset was archived. If a dataset was archived more than once (for example, if it was reprocessed by the pipeline), then this will show the *latest* archive date.

About 75% of all science datasets are archived within 24 hours after the end of the observation. (delays longer than this are usually due to problems in pipeline calibration, or if the data stream gets backed up. Delays like this are rare, however, and are more likely to apply to the newer instruments early in their careers.)

The Archive Date was added to the HST Archive Search on 1998 Feb 19.

Output Columns

Your choice of what columns you want to see in the output. There are two radio buttons that let you select either the default set of columns, or choose your own set of columns.

You can select your own output columns by pressing the `custom...` radio button and selecting the columns from the list below it. (`Mark` is pre-selected for you.) The output columns will be in the order in which they appear in this list.

Sort output by:

Choose how you want the output rows sorted. You can select up to three fields to sort on. the rows will be sorted in the order of the first sort field; if two rows have the same sort field, they will be sorted in order of the second sort field, and so on.

For each field, you can select that the rows be sorted in *reverse* order on that field by selecting the `reverse` checkbox. For example, you can sort the rows with the most recent observations first by selecting `Observation Date` for the first sort field and selecting the `reverse` checkbox next to it.

Maximum number of hits

Some queries will be capable of returning thousands of rows or more. Such large search results tend to use up memory on both the client and server sides, and aren't usually useful. By default, we limit the number of rows displayed to 100 rows, but you can increase (or decrease) this limit as needed.

Output equinox

Just what you'd think: the equinox of the coordinates displayed in the output. *This doesn't work yet.*

Show SQL Query

Select this checkbox if you want to see the SQL query that the HST Search engine constructs from your query qualifications. The query will be shown at the end of the search results.

SQL (Standard Query Language, pronounced either "ess cue ell" or "sequel") is a language used by most relational database systems for retrieving information from database tables. The HST Search Page takes your search specifications and converts them to an SQL query to run on our database. Viewing the generated query is often useful for debugging, and may also be useful for SQL-literate users who want to see what logic was used in the query. (In fact, this may be useful for most people, since SQL is pretty easy to understand.)

JPG GrayScale ADU : 0 to 20 JPG Quality : 30

This catalog of over 210,000 faint galaxies and stars is based on observations with the European Space Agency (ESA) and National Aeronautics and Space Administration (NASA) Hubble Space Telescope (HST).

The catalog contains data from 387 Wide Field Planetary Camera (WFPC2) fields taken in pure parallel mode for the Medium Deep Survey (MDS), Guaranteed Time Observations (GTO), and from the HST Data Archive primary observations of 54 galaxy cluster fields and 81 random fields which match the MDS survey criteria, including the Hubble Deep Field.

The data is obtained from the Space Telescope Science Institute (STScI), which is operated by the Association of Universities for Research in Astronomy inc. (AURA) under NASA contract NAS5-26555. The analysis is funded by the HST WFPC2 Science Team and STScI grants GO2684, GO6951, and GO7536 to Prof. Richard Griffiths and Dr Kavan Ratnatunga at Carnegie Mellon University (CMU).

The analysis uses automated maximum likelihood 2-Dimensional image analysis software developed by Dr. Kavan Ratnatunga. The MDS pipeline data reduction was done by Eric Ostrander, and continued by Adam Knudson. We gratefully acknowledge help from Dr Stefano Casertano, Dr Myungshin Im, Dr Avi Naim and Dr Lyman Neuschaefer who were for some years associated with the MDS pipeline.

FUSE Science Search Help

This page describes how to use the FUSE Science Search form and describes the individual fields in the form. For information about FUSE and its data, see the FUSE homepage at http://fuse.pha.jhu.edu/.

Use the FUSE Science Search form to locate and retrieve observations from the FUSE data archive at STScI. Both public and proprietary data may be retrieved through this interface.

The FUSE Science Search form offers a view of FUSE *observations*, which comprise one or more *exposures*. To locate individual exposures, use the FUSE Exposures Search page. More information about retrieving FUSE data may be found on the FUSE retrieval help page.

Object Name
The name of the astronomical object you want to search for.

Resolver
The name resolver you want to use, if you want to get an object's coordinates. To resolve an object's name into its coordinates, enter the object name in the **Object Name** field, select either NED or SIMBAD for the resolver, and hit the **Resolve** button. The form will be redrawn with the object's right ascension and declination entered as defaults in the **RA** and **Dec** fields. Resolving an object name will *not* change any other choices made in the form.

If you enter an object name and select either SIMBAD or NED, and then hit the "Search" button, the script will get the coordinates before doing the search. A message will appear at the top of the results page showing you what coordinates were found for the object (or an error message if the name resolver didn't work for some reason).

We recommend that you use object-name resolution to find observations of fixed targets in the database. This is the most reliable way to look up observations, because the observer could have given the observation any name at all (for example, `NGC1976` instead of `M42`). However, if you do know the name that the observer gave as the object, you can select FUSE Target Name. In that case, the object name will not be resolved into coordinates, but will be used as a search qualification in the database. (Remember when you do this to *not* press the **Resolve** button.)

The SIMBAD and NED object name resolvers can only resolve the names of fixed astronomical object; they cannot compute the positions of moving objects (planets, comets, etc.).

Resolve
When you press this button, the FUSE Science form will be redrawn with the coordinates of the object name entered into the RA and Dec fields.

RA,Dec
The Right Ascension and Declination around which you want to search. A number of formats are accepted for the RA and Dec. Here are some examples:

```
Decimal Degrees
    185.63325 29.8959861111111

Hours, minutes and Seconds
    12 22 31.98      29 53 45.55
    12h22m31.98s     29d53m45.55s
    12:22:31.98     +29:53:45.55
    12h22'31.98"     29d53'45.55"
    12h 22m 31.98s   29d 53m 45.55s
    12h 22' 31.98"   29d 53' 45.55"
    12h 22' 31.98"  -29d 53' 45.55"
    12h22'31".98    -29d53'45".55
    12h22m31s.98    -29o53m45s.55
    12h 22' 31".98  -29d 53' 45".55

Hours/Degrees and Minutes (no seconds)
    12 22     29 53
    12h22m   +29d53m
    12h22m    29d53m
    12:22m    29:53m
    12h22'    29d53'
    12h 22m   29d 53m
    12h 22'   29d 53'
    12h 22'  -29d 53'

The RA may be given in decimal degrees by indicating
a D or d after the degrees:
    12d 22m   29d 53m
```

Spacing is not important, as long as the value is unambiguous, and that you can delimit the hours/degrees, minutes, and (optional) seconds with letters, colons, spaces, or any character that's not a digit or a decimal point.

Note also that seconds of the form 31".98 or 31s.98 are accepted. This should make it easy to cut and paste values into these fields from electronic publications.

Radius
How far around the search position you would like to search, in arcminutes. You can specify either a single number or a range. A single number means "all observations whose positions are less than this many arcminutes from the given position". A range can be given to get observations within a torus around a position; for example, "5 .. 20" will find observations between 5 and 20 arcminutes from the search position.

Equinox
The equinox of the RA and Dec you have entered, either B1950 or J2000. This only affects the input coordinates; the output coordinates will always be J2000.

Observation-level Information

Observation Date
The date of the observation. More specifically, the date and time, in GMT, on which the exposure was started. When specifying this date, you need to include a date and an optional time. The date can have any of the following formats (the month name can be spelled out or abbreviated to three letters; case is not significant):

```
Jul 15 1994
Jul 1994 15
15 Jul 1994
1994 Jul 15
1994 15 Jul
7/15/1994
7-15-1994
7.15.1994
```

If the day is omitted, the first day of the month is assumed. This means that a specification like "July 1994" will look for observations done on July 1 1994 00:00:00, *not* for observations done during July 1994. Note also that when entering a date with the month in numerical format, the American ordeing is used; i.e., the first number is the month.

If a time is omitted, then midnight (00:00:00) is assumed. Otherwise, you can specify a time in any of these formats:

```
14:30
14:30:20
14:30:20:999
14:30:20.9
4am
4 PM
04:30:20 AM
```

To search for observations before a given date, use <, and for observations after a given date, use >. For example,

```
> Jul 15 1994
< Jul 15 1994
```

You can use the .. operator to search on a range of dates:

```
Jul 1 1994 .. Aug 1 1995
```

This operator is inclusive on the first date and exclusive on the second.

Finally, you can search on a list of dates or date ranges. For example,

```
Jul 1 1994 .. Jul 3 1994, Dec 1 1995 .. Dec 6 1995
```

will search for observations done within either one of these date ranges.

Exp Time
The total exposure time of the observation, in seconds. You can use operators or ranges in this field; for example,

```
< 100
> 1000.0
100 .. 1000
```

To exclude a range of exposures, use a comma:

```
< 100, > 1000
```

Observer
The last name of the principal investigator of the observation. We sometimes refer to this person as the "observer".

Program
The FUSE proposal identifier under which the observation was executed. This can be an alphanumeric ID or a comma-separated list of alphaumeric IDs.

Archive Date
This is the date on which a dataset was archived. If a dataset was archived more than once (for example, if it was reprocessed by the pipeline), then this will show the *latest* archive date.

Release date
Select the release date for the data. See the observation date for the entry format. FUSE data has a nominal proprietary period of one year (though in special cases, this may be shortened or extended). The Release Date field gives the end of the dataset's proprietary period.

When the results of a search query are displayed, both public and proprietary datasets will have mark buttons. Proprietary datasets will have an at symbol, @, next to the mark button, and on most browsers, the background for proprietary mark buttons will be yellow. Properly authorized users will be able to retrieve proprietary data through the Web interface.

Observation Name
The Observation name is the unique identifier for a FUSE observation. (For FUSE, an observation is an association of exposures.) This value can be wildcarded using a `*`.

Output Options

Output Columns
Your choice of what columns you want to see in the output. There are two radio buttons that let you select either the default set of columns, or choose your own set of columns.

You can select your own output columns by pressing the `custom...` radio button and selecting the columns from the list below it. (`Mark` is pre-selected for you.) The output columns will be in the order in which they appear in this list.

Sort output by:

Choose how you want the output rows sorted. You can select up to three fields to sort on. the rows will be sorted in the order of the first sort field; if two rows have the same sort field, they will be sorted in order of the second sort field, and so on.

For each field, you can select that the rows be sorted in *reverse* order on that field by selecting the `reverse` checkbox. For example, you can sort the rows with the most recent observations first by selecting `Observation Date` for the first sort field and selecting the `reverse` checkbox next to it.

Maximum number of hits

Some queries will be capable of returning thousands of rows or more. Such large search results tend to use up memory on both the client and server sides, and aren't usually useful. By default, we limit the number of rows displayed to 100 rows, but you can increase (or decrease) this limit as needed.

Show SQL Query

Select this checkbox if you want to see the SQL query that the FUSE Search engine constructs from your query qualifications. The query will be shown at the end of the search results.

SQL (Standard Query Language, pronounced either "ess cue ell" or "sequel") is a language used by most relational database systems for retrieving information from database tables. The FUSE Search Page takes your search specifications and converts them to an SQL query to run on our database. Viewing the generated query is often useful for debugging, and may also be useful for SQL-literate users who want to see what logic was used in the query. (In fact, this may be useful for most people, since SQL is pretty easy to understand.)

If you have problems retrieving your data, you can contact the help desk via the link at the bottom of this page.

FUSE Exposure Search Help

This page describes the FUSE Exposure Search form and the individual fields in the form. For information about FUSE and its data, see the FUSE homepage at http://fuse.pha.jhu.edu/.

Use the FUSE Exposure Search form to locate and retrieve observations from the FUSE data archive at STScI. Both public and proprietary data may be retrieved through this interface.

The FUSE Exposure Search form offers a view of FUSE *exposures*, which make up *observations*. To locate observations, use the FUSE Science Search page. More information about retrieving FUSE data may be found on the FUSE retrieval help page.

Object Name

The name of the astronomical object you want to search for.

Resolver

The name resolver you want to use, if you want to get an object's coordinates. To resolve an object's name into its coordinates, enter the object name in the **Object Name** field, select either NED or SIMBAD for the resolver, and hit the **Resolve** button. The form will be redrawn with the object's right ascension and declination entered as defaults in the **RA** and **Dec** fields. Resolving an object name will *not* change any other choices made in the form.

If you enter an object name and select either SIMBAD or NED, and then hit the "Search" button, the script will get the coordinates before doing the search. A message will appear at the top of the results page showing you what coordinates were found for the object (or an error message if the name resolver didn't work for some reason).

We recommend that you use object-name resolution to find observations of fixed targets in the database. This is the most reliable way to look up observations, because the observer could have given the observation any name at all (for example, `NGC1976` instead of `M42`). However, if you do know the name that the observer gave as the object, you can select FUSE Target Name. In that case, the object name will not be resolved into coordinates, but will be used as a search qualification in the database. (Remember when you do this to *not* press the **Resolve** button.)

The SIMBAD and NED object name resolvers can only resolve the names of fixed astronomical object; they cannot compute the positions of moving objects (planets, comets, etc.).

Resolve

When you press this button, the search form will be redrawn with the coordinates of the object name entered into the RA and Dec fields.

RA,Dec

The Right Ascension and Declination around which you want to search. A number of formats are accepted for the RA and Dec. Here are some examples:

```
Decimal Degrees
    185.63325 29.8959861111111

Hours, minutes and Seconds
    12 22 31.98      29 53 45.55
    12h22m31.98s     29d53m45.55s
    12:22:31.98     +29:53:45.55
    12h22'31.98"     29d53'45.55"
    12h 22m 31.98s   29d 53m 45.55s
    12h 22' 31.98"   29d 53' 45.55"
    12h 22' 31.98"  -29d 53' 45.55"
    12h22'31".98    -29d53'45".55
    12h22m31s.98    -29o53m45s.55
    12h 22' 31".98  -29d 53' 45".55

Hours/Degrees and Minutes (no seconds)
    12 22     29 53
    12h22m   +29d53m
    12h22m    29d53m
    12:22m    29:53m
    12h22'    29d53'
    12h 22m   29d 53m
    12h 22'   29d 53'
    12h 22'  -29d 53'

The RA may be given in decimal degrees by indicating
a D or d after the degrees:
    12d 22m   29d 53m
```

Spacing is not important, as long as the value is unambiguous, and that you can delimit the hours/degrees, minutes, and (optional) seconds with letters, colons, spaces, or any character that's not a digit or a decimal point.

Note also that seconds of the form 31".98 or 31s.98 are accepted. This should make it easy to cut and paste values into these fields from electronic publications.

Radius

How far around the search position you would like to search, in arcminutes. You can specify either a single number or a range. A single number means "all observations whose positions are less than this many arcminutes from the given position". A range can be given to get observations within a torus around a position; for example, "5 .. 20" will find observations between 5 and 20 arcminutes from the search position.

Equinox

The equinox of the RA and Dec you have entered, either B1950 or J2000. This only affects the input coordinates; the output coordinates will always be J2000.

Observation-level Information

Observation Date

The date of the observation. More specifically, the date and time, in GMT, on which the exposure was started. When specifying this date, you need to include a date and an optional time. The date can have any of the following formats (the month name can be spelled out or abbreviated to three letters; case is not significant):

```
Jul 15 1994
Jul 1994 15
15 Jul 1994
1994 Jul 15
1994 15 Jul
7/15/1994
7-15-1994
7.15.1994
```

If the day is omitted, the first day of the month is assumed. This means that a specification like "July 1994" will look for observations done on July 1 1994 00:00:00, *not* for observations done during July 1994. Note also that when entering a date with the month in numerical format, the American ordeing is used; i.e., the first number is the month.

If a time is omitted, then midnight (00:00:00) is assumed. Otherwise, you can specify a time in any of these formats:

```
14:30
14:30:20
14:30:20:999
14:30:20.9
4am
4 PM
04:30:20 AM
```

To search for observations before a given date, use <, and for observations after a given date, use >. For example,

```
> Jul 15 1994
< Jul 15 1994
```

You can use the .. operator to search on a range of dates:

```
Jul 1 1994 .. Aug 1 1995
```

This operator is inclusive on the first date and exclusive on the second.

Finally, you can search on a list of dates or date ranges. For example,

```
Jul 1 1994 .. Jul 3 1994, Dec 1 1995 .. Dec 6 1995
```

will search for observations done within either one of these date ranges.

Exp Time

The total exposure time of the observation, in seconds. You can use operators or ranges in this field; for example,

```
< 100
> 1000.0
100 .. 1000
```

To exclude a range of exposures, use a comma:

```
< 100, > 1000
```

Observer

The last name of the principal investigator of the observation. We sometimes refer to this person as the "observer".

Program
The FUSE proposal identifier under which the observation was executed. This can be an alphanumeric ID or a comma-separated list of alphaumeric IDs.

Archive Date
This is the date on which a dataset was archived. If a dataset was archived more than once (for example, if it was reprocessed by the pipeline), then this will show the *latest* archive date.

Release date
Select the release date for the data. See the observation date for the entry format. FUSE data has a nominal proprietary period of one year (though in special cases, this may be shortened or extended). The Release Date field gives the end of the dataset's proprietary period.

When the results of a search query are displayed, both public and proprietary datasets will have mark buttons. Proprietary datasets will have an at symbol, @, next to the mark button, and on most browsers, the background for proprietary mark buttons will be yellow. Properly authorized users will be able to retrieve proprietary data through the Web interface.

Observation Name
The Observation name is the unique identifier for a FUSE observation. (For FUSE, an observation is an association of exposures.) This value can be wildcarded using a *.

Exposure-level Information

Exposure Date
The date of the start of the exposure. (Note that one observation can include several expoosures.) See observation date entry above for information on formatting date entry.

Exposure ID
Exposure ID from data header. This 3-digit number uniquely defines each exposure obtained during a single observation. The exposure ID plus the association ID is equivalent to the exposure name (otherwise known as the rootname). To search for a particular exposure (e.g. A0030102006) by name, one must specify both a value for the observation name (e.g., A0030102000) and the exposure ID (e.g., 006).

Instrument Mode
Instrument mode (either TTAG or HIST).

Planned Aperture Name
planned target aperture (PINH, HIRS, MDRS, or LWRS).

Total Count Rate
The total count rate (in counts/sec), specified as a real number, for a particular exposure.

FP Split?
Number of FP split positions (?).

FES Filter
FES filter wheel position (CLR=Clear, COL=color, ND=Neutral Density)

FES Target Pos
FES target position: (IN or OUT)

Output Options

Output Columns
Your choice of what columns you want to see in the output. There are two radio buttons that let you select either the default set of columns, or choose your own set of columns.

You can select your own output columns by pressing the `custom...` radio button and selecting the columns from the list below it. (`Mark` is pre-selected for you.) The output columns will be in the order in which they appear in this list.

Sort output by:
Choose how you want the output rows sorted. You can select up to three fields to sort on. the rows will be sorted in the order of the first sort field; if two rows have the same sort field, they will be sorted in order of the second sort field, and so on.

For each field, you can select that the rows be sorted in *reverse* order on that field by selecting the `reverse` checkbox. For example, you can sort the rows with the most recent observations first by selecting `Observation Date` for the first sort field and selecting the `reverse` checkbox next to it.

Maximum number of hits
Some queries will be capable of returning thousands of rows or more. Such large search results tend to use up memory on both the client and server sides, and aren't usually useful. By default, we limit the number of rows displayed to 100 rows, but you can increase (or decrease) this limit as needed.

Show SQL Query
Select this checkbox if you want to see the SQL query that the FUSE Search engine constructs from your query qualifications. The query will be shown at the end of the search results.

SQL (Standard Query Language, pronounced either "ess cue ell" or "sequel") is a language used by most relational database systems for retrieving information from database tables. The FUSE Search Page takes your search specifications and converts them to an SQL query to run on our database. Viewing the generated query is often useful for debugging, and may also be useful for SQL-literate users who want to see what logic was used in the query. (In fact, this may be useful for most people, since SQL is pretty easy to understand.)

---

 archive@stsci.edu

IUE Search Help

Use the **IUE search form** to search the IUE Archive Catalog by object name, position, observation date, program ID, etc. and to specify the output format. You can also mark data for retrieval using this interface.

Object Name

The name of the astronomical object you want to search for. Examples of valid names include gam Gem, NGC 1068, JUPITER, and hd 45677.

When you search on the object name in the database (i.e. without using the name resolver), case will be ignored. The object name will *not* be wildcarded at the front and back automatically (that's so if you innocently enter `IO`, you don't match things like `ORION`). You can however wildcard the object name using `*` (for example, `*IO*`). You can also enter a comma-separated list; for example, `*JUP*,*SAT*` would match object names containing either `JUP` or `SAT`.

Object Resolver

The name resolver you want to use, if you want to resolve an object into its coordinates. You can resolve an object name either before a search, or you can redraw the form with the resolved coordinates in place. You can also elect not to resolve the object name when doing the search, but to search the IUE database on the object name given.

To resolve an object name before a search, enter the object name in the **Object Name** field, select either `NED` or `SIMBAD` for the resolver, and hit the **Search** button. NED is the NASA Extragalactic Database at Caltech in Pasadena, California, and SIMBAD is the Set of Identifications, Measurements, and Bibliography for Astronomical Data at the Centre de Données astronomiques in Strasbourg, France. The object name will be sent to the chosen resolver, which will send back the coordinates. (If the object name is not recognized by the resolver, or there is some other problem with the SIMBAD or NED services, then the search form will be redrawn with an error message at the top.) These coordinates will then be used to search the IUE database, along with whatever other query qualifications you have given.

You can also hit the **Get coordinates** button instead of the **Search** button. In that case, the search form will be redrawn with the object's right ascension and declination entered as defaults in the **RA** and **Dec** fields. Resolving an object name will not change any other choices made in the form, except for the equinox, which will be reset to J2000 (since both the SIMBAD and NED resolvers return J2000 coordinates).

We recommend that you use object name resolution to find observations of specific objects in the database. This is the most reliable way to look up observations, because the observer could have given any object name at all (for example, `NGC1976` instead of `M42`, or `PARALLEL-FIELD`). However, if you do know the object name that the observer used, you can select `Don't resolve`, in which case the object name will not be resolved into coordinates, but will be used as a search qualification in the database. (This will happen only when you press the **Search** button.)

The SIMBAD and NED object name resolvers can resolve only fixed objects; they cannot compute the positions of moving objects (planets, comets, etc.). To find moving objects, try selecting the appropriate object class, entering an object name that could match what you're looking for, and selecting `Don't resolve` for the name resolver. NED is an extragalactic database, and generally won't resolve object names within the Milky Way galaxy.

Resolve

When you select either `NED` of `SIMBAD` for the resolver and then press the "Get coordinates" button, the IUE Search form will be redrawn with the coordinates for the given object entered into the RA and Dec fields. If you then press **Search**, the search will be conducted on that position. (The resolver will *not* be re-run for the search, unless you change either the object name or the resolver).

RA, Dec

The Right Ascension and Declination around which you want to search. A number of formats are accepted for the RA and Dec. Here are some examples:

```
Decimal Degrees
    185.63325 29.8959861111111

Hours, minutes and Seconds
    12 22 31.98       29 53 45.55
    12h22m31.98s      29d53m45.55s
    12:22:31.98      +29:53:45.55
    12h22'31.98"      29d53'45.55"
    12h 22m 31.98s    29d 53m 45.55s
    12h 22' 31.98"    29d 53' 45.55"
    12h 22' 31.98"   -29d 53' 45.55"
    12h22'31".98     -29d53'45".55
    12h22m31s.98     -29o53m45s.55
    12h 22' 31".98   -29d 53' 45".55

Hours/Degrees and Minutes (no seconds)
    12 22      29 53
    12h22m   +29d53m
    12h22m    29d53m
    12:22m    29:53m
    12h22'    29d53'
    12h 22m   29d 53m
    12h 22'   29d 53'
    12h 22'  -29d 53'

The RA may be given in decimal degrees by indicating
a D or d after the degrees:
    12d 22m   29d 53m
```

Spacing is not important, as long as the value is unambiguous, and that you can delimit the hours/degrees, minutes, and (optional) seconds with letters, colons, spaces, or any character that's not a digit or a decimal point.

Note also that seconds of the form 31".98 or 31s.98 are accepted. This should make it easy to cut and paste values into these fields from electronic publications.

Radius

The radius of the search box around the RA and Dec, in floating-point arcminutes (e.g., `5.0`). You should be careful about giving too restrictive a search radius in an IUE search: the coordinates are coordinates of the *object* as given by the Guest Observer, and since acquisitions were made in real time, these coordinates may not reflect the precise pointing of IUE at the time of the observation.

Equinox

The equinox of the RA and Dec you have entered, either `B1950` or `J2000`. This only affects the input coordinates; there is a separate selector for the equinox of the output coordinates.

If you hit the **Resolve** button to get an object's coordinates and redraw the form, the equinox will be set to `J2000`, since that's the equinox of the coordinates returned by the object name resolvers.

Exp. Time

The commanded exposure time, in seconds. You can use operators or ranges in this field; for example,

```
< 100
> 1000
100 .. 1000
```

You can *exclude* a range of exposure times using a comma:

```
< 100, > 1000
```

Observation Date

The date and time, in GMT, on which the exposure was started. When specifying this date, you need to include at least a date; a time is optional. The date can have any of the following formats (the month name can be spelled out or abbreviated to three letters; case is not significant):

```
Jul 15 1994
Jul 1994 15
15 Jul 1994
1994 Jul 15
1994 15 Jul
7/15/1994
7-15-1994
7.15.1994
```

If the day is omitted, the first day of the month is assumed. This means that a specification like "July 1994" will look for observations done on July 1 1994 00:00:00, *not* for observations done during July 1994. Note also that when entering a date with the month in numerical format, the American ordering is used; i.e., the first number is the month.

If a time is omitted, then any time for that day will match. Otherwise, you can specify a time in any of these formats:

```
14:30
14:30:20
14:30:20:999
14:30:20.9
4am
4 PM
04:30:20 AM
```

To search for observations before a given date, use <, and for observations after a given date, use >. For example,

```
> Jul 15 1994
< Jul 15 1994
```

You can use the .. operator to search on a range of dates:

```
Jul 1 1994 .. Aug 1 1995
```

This operator is inclusive on the first date and exclusive on the second.

Finally, you can search on a list of dates or date ranges. For example,

```
Jul 1 1994 .. Jul 3 1994, Dec 1 1995 .. Dec 6 1995
```

will search for observations done within either one of these date ranges.

Program ID

An alphanumeric code identifying the IUE observing program under which the observation was made; for example, `KQ120`. The program IDs were assigned for each episode of observing proposals. NASA, ESA, and SERC followed different naming conventions.

This field may be wildcarded using `*` to match any character.

Class

IUE Object Class code. An IUE classification system used for categorizing IUE observations. The object class was specified by the Guest Observer; thus, one object may be archived under more than one object class.

Object Classes 98 (Wavelength Calibration Lamp) and 99 (Nulls and Flat Fields) are excluded from the search results unless they are explicitly selected.

Multiple object classes may be searched at one time.

Camera

The camera used in the observation. Approximate wavelength ranges for absolutley calibrated data:

Camera	Wavelength Range (Å)
SWP	1150 - 1975
LWP	1850 - 3350
LWR	1850 - 3350

Data may be available for extracted "net flux" files over more extended wavelength ranges.

SWR was rarely used due to malfunction.

Dispersion

High dispersion (`High`) mode produces a two-dimensional echelle spectrum containing approximately 60 orders, with a resolution of roughly 0.2 Å. Low dispersion (`Low`) mode produces a single spectrum, or two if both apertures were used, with lower spectral resolution, approximately 6 Å.

Aperture

The aperture used in the observation.

Each spectrograph has a pair of entrance apertures, consisting of a large approximately 10 x 20 arcsecond oval and a small 3 arcsecond diameter circle. The image size at the focal plane is typically about 3 arcseconds for a point source. Spectra may be trailed along the large aperture. In addition, multiple exposures may be offset within in the large aperture to create a pseudo-trailed spectrum or series of time resolved spectra. The throughput of the small aperture varied significantly depending on the object centering and tracking, with a maximum throughput of about 60%. Thus most point-source spectra were taken using the large aperture. The aperture field is left blank only when the dispersion is not applicable (e.g., flat field images).

Image ID

The camera name plus a sequential number used to distinguish each image within the data set for that camera; for example, `LWP01408`. The image number will always be five digits, with leading zeros if necessary. However, if you enter something like `LWP1408`, the IUE Search engine will fill in the leading zeroes for you and search for `LWP01408`. If you want anything starting with LWP1408, then use a wildcard, like this: `LWP1408*`.

The numbering began at 1000, but a handful of images with duplicated image numbers were reassigned with numbers in the 500's. Some image numbers were accidentally skipped as well.

If you enter a qualification in this field, then the **Camera**, **Dispersion**, and **Aperture** qualifications in the form will be ignored. HOWEVER other qualifications such as object class will NOT be ignored.

Output Columns

Your choice of what columns you want to see in the output. There are two radio buttons that let you select either the default set of columns, or choose your own set of columns.

The default set of columns is:

```
Mark
Object Name
Image ID
Disp
Aper
Obs Date
RA (J2000)
Dec (J2000)
Exp Length
Program
Class
More info
```

You can select your own output columns by pressing the `custom...` radio button and selecting the columns from the list below it. (`Mark` is pre-selected for you.) The output columns will be in the order in which they appear in this list. Note: Window users need to hold down the Ctrl key while clicking specific columns to be displayed. For selecting a group of columns, press the shift key and click the first and last entries.

Sort output by:

Choose how you want the output rows sorted. You can select up to three fields to sort on. The rows will be sorted in the order of the first sort field; if two rows have the same sort field, they will be sorted in order of the second sort field, and so on.

For each field, you can select that the rows be sorted in *reverse* order on that field by selecting the `reverse` checkbox. For example, you can sort the rows with the most recent observations first by selecting `Observation Date` for the first sort field and selecting the `reverse` checkbox next to it.

Maximum number of hits

Some queries will be capable of returning thousands of rows or more. such large search results tend to use up memory on both the client and server sides, and aren't usually useful. By default, we limit the number of rows displayed to 100 rows, but you can increase (or decrease) this limit as needed.

Output equinox

Just what you'd think: the equinox of the coordinates displayed in the output.

Show SQL Query

Select this checkbox if you want to see the SQL query that the IUE Search engine constructs from your query qualifications. The query will be shown at the end of the search results.

SQL (Standard Query Language, pronounced either "ess cue ell" or "sequel") is a language used used by most relational database systems for retrieving information from database tables. The IUE Search Page takes your search specifications and converts them to an SQL query to run on our database. Viewing the generated query is often useful for debugging, and may also be useful for SQL-literate users who want to see what logic was used in the query. (In fact, this may be useful for most people, since SQL is pretty easy to understand.)

EUVE Search Help

The search pages basically contain 3 parts. The top of the page lists the input search fields. Entering values (as described below) for one or more of these fields will define the selection criteria for the database search. The middle of the form contains buttons to initiate various actions including:

1. perform the search using the specified search criteria and output format,
2. clear the search form and reset values to the original defaults,
3. reset entries to the set of (default) values used the previous time the search page was drawn, and
4. display this help page.

The bottom portion of the page deals with formatting the table of found entries that appears after the search is completed. The format options include specifying which columns appear in the output list, the order of the entries, the maximum number of returned entries, the epoch of the output coordinates, and the option to display the actual SQL command used to retrieve the database entries. First time users may want to run the search using the default output options.

After selecting search criteria, output options, and clicking the search button, a second page will appear listing the returned database entries. From this table, one may click on the data file entries to download the selected FITS file.

> **Note** Currently all the data requested through this interface will be retrieved from HEASARC at Goddard Space Flight Center.

Object Name

The name of the astronomical object you want to search for. Examples of valid names include NGC 1360, PN LOTR 5, and JUPITER. This is the official name under which targets were processed for the EUVE Archive. It is not necessarily the name under which the target was originally proposed or observed. A single name was consistently used thoughout the archive for targets which were observed more than once.

When you search on the object name in the database, case will be ignored. The object name will *not* be wildcarded at the front and back (that's so if you innocently enter `IO`, you don't match things like `ORION`). You can wildcard the object name using `*`, however (for example, `*IO*`). You can also enter a comma-separated list; for example, `*JUP*,*SAT*` would match object names containing either `JUP` or `SAT`.

The SIMBAD and NED object name resolvers can only resolve fixed objects; they cannot compute the positions of moving objects (planets, comets, etc.). To find moving objects, try selecting the appropriate object class, entering an object name that could match what you're looking for, and selecting `Don't resolve` for the name resolver. NED is an extragalactic database, and generally won't resolve object names within the Milky Way galaxy.

Object Resolver

The name resolver will let you resolve an object name into its coordinates. This is useful particularly for searching for objects that may be known by different names. You can resolve an object name either before a search, or you can redraw the form with the the resolved coordinates in place. If you don't elect to to resolve the object name, the EUVE database will be searched on the object name given.

The SIMBAD and NED object name resolvers can only resolve fixed objects; they cannot compute the positions of moving objects (planets, comets, etc.). To find moving objects, try selecting the appropriate object class, entering an object name that could match what you're looking for, and selecting `Don't resolve` for the name resolver. NED is an extragalactic database, and generally won't resolve object names within the Milky Way galaxy.

To resolve an object name before a search, enter the object name in the **Object Name** field, select either `SIMBAD` or `NED` for the resolver, and hit the **Search** button. (NED is the Nasa Extragalactic Database at Caltech in Pasadena, California, and SIMBAD is the Set of Identifications, Measurements, and Bibliography for Astronomical Data at the Centre de Données astronomiques in Strasbourg, France.) The object name will be sent to SIMBAD, which will send back the coordinates. (If the object name is not recognized by the resolver, or there is some other problem with the SIMBAD service, then the search form will be redrawn with an error message at the top.) These coordinates will then be used to search the EUVE database, along with whatever other query qualifications you have given.

You can also hit the **Resolve** button instead of the **Search** button. In that case, the search form will be redrawn with the object's right ascension and declination entered as defaults in the **RA** and **Dec** fields. Resolving an object name will not change any other choices made in the form, except for the equinox, which will be reset to J2000 (since the SIMBAD resolver returns J2000 coordinates).

We recommend that you use object name resolution to find observations of specific objects in the database. This is the most reliable way to look up observations, because the observer could have given any object name at all (for example, `NGC1976` instead of `M42`). However, if you do know the object name that the observer used, you can select `Don't resolve`, in which case the object name will not be resolved into coordinates, but will be used as a search qualification in the database. (This will happen only when you press the **Search** button.)

Resolve

When you press this button and select `SIMBAD` for the resolver, the EUVE Search form will be redrawn with the coordinates for the given object entered into the RA and Dec fields. If you then press **Search**, the search will be conducted on that position. (The resolver will *not* be re-run for the search, unless you change either the object name or the resolver).

RA, Dec

The Right Ascension and Declination around which you want to search. These fields give the J2000 equatorial coordinates used as the coordinates of the source when processing the data. These are not necessarily the same as the coordinates used to point the spacecraft during the observation. They are typically either taken from SIMBAD (with proper motions applied) or were supplied by the Guest Observer. We have the same coordinates throughout the archive for multiple observations of the same source except in certain special cases. A number of formats are accepted for the RA and Dec. Here are some examples:

```
Decimal Degrees
    185.63325 29.8959861111111

Hours, minutes and Seconds
    12 22 31.98      29 53 45.55
    12h22m31.98s     29d53m45.55s
    12:22:31.98     +29:53:45.55
    12h22'31.98"     29d53'45.55"
    12h 22m 31.98s   29d 53m 45.55s
    12h 22' 31.98"   29d 53' 45.55"
    12h 22' 31.98"  -29d 53' 45.55"
    12h22'31".98    -29d53'45".55
    12h22m31s.98    -29o53m45s.55
    12h 22' 31".98  -29d 53' 45".55

Hours/Degrees and Minutes (no seconds)
    12 22     29 53
    12h22m   +29d53m
    12h22m    29d53m
    12:22m    29:53m
    12h22'    29d53'
    12h 22m   29d 53m
    12h 22'   29d 53'
    12h 22'  -29d 53'

The RA may be given in decimal degrees by
indicating a D or d after the degrees:
    12d 22m   29d 53m
```

Spacing is not important, as long as the value is unambiguous, and that you delimit the hours/degrees, minutes, and (optional) seconds with letters, colons, spaces, or any character that's not a digit or a decimal point.

Note also that seconds of the form 31".98 or 31s.98 are accepted. This should make it easy to cut and paste values into these fields from electronic publications.

Radius

The radius of the search box around the RA and Dec, in floating-point arcminutes (e.g., `5.0`). You should be careful about giving too restrictive a search radius in an EUVE search.

Equinox

The equinox of the RA and Dec you have entered, either `B1950` or `J2000`. This only affects the input coordinates; there is a separate selector for the equinox of the output coordinates.

If you hit the **Resolve** button to get an object's coordinates and redraw the form, the equinox will be set to `J2000`, since that's the equinox of the coordinates returned by the object name resolvers.

Object Category

This is a broad category for the target. Values include:

- **wd** - white dwarfs
- **late** - late-type stars
- **early** - early-type stars
- **cv** - cataclysmic variables
- **ex** - extragalactic objects
- **ss** - solar system objects
- **pulsar** - pulsars
- **pn** - planetary nebulae
- **noid** - unidentified
- **lmxb** - low-mass X-ray binaries
- **snr** - supernova remnants
- **grb** - gamma-ray bursters
- **other** - none of the above

Observation Start Date

This is the GMT time, to the nearest second, of the start of the observation. The target name and observation date together serve to uniquely identify each EUVE observation. (Note the first EUVE observation was obtained in June, 1992.)

When specifying this date, you need to include at least a date; a time is optional. The date can have any of the following formats (the month name can be spelled out or abbreviated to three letters; case is not significant):

```
Jul 15 1994
Jul 1994 15
15 Jul 1994
1994 Jul 15
1994 15 Jul
7/15/1994
7-15-1994
7.15.1994
```

If the day is omitted, the first day of the month is assumed. This means that a specification like "July 1994" will look for observations done on July 1 1994 00:00:00, *not* for observations done during July 1994. Note also that when entering a date with the month in numerical format, the American ordering is used; i.e., the first number is the month.

If a time is omitted, then any time for that day will match. Otherwise, you can specify a time in any of these formats:

```
14:30
14:30:20
14:30:20:999
14:30:20.9
4am
4 PM
04:30:20 AM
```

To search for observations before a given date, use <, and for observations after a given date, use >. For example,

```
> Jul 15 1994
< Jul 15 1994
```

You can use the .. operator to search on a range of dates:

```
Jul 1 1994 .. Aug 1 1995
```

This operator is inclusive on the first date and exclusive on the second.

Finally, you can search on a list of dates or date ranges. For example,

```
Jul 1 1994 .. Jul 3 1994,
Dec 1 1995 .. Dec 6 1995
```

will search for observations done within either one of these date ranges.

Exposure Time

This is the median exposure for a given observation. There are four EUVE detectors which normally collect data simultaneously during an observation. Each detector will have a different exposure time. In this field, we have listed the median of the exposures of the individual detectors, in units of kiloseconds and rounded off to the nearest kilosecond. Note that sometimes one detector can be way off from the others and skew this number, or an observation can be very short producing an exposure time of zero. For the true exposure times you need to look in the headers of the images.fit extensions. The units can optionally be specified in seconds, although kiloseconds is the default used by the project.

Day/Night

Entries will contain either the word "night" or "day" indicating which part of the observation is being cataloged. Some observations will have both parts, others will only have a night part. Sometimes the night and day parts appear on different volumes. By default, both day and night observations will be returned. To not retrieve one or the other, click on the entry not desired.

Observer

The name of the PI of the proposal which has been associated with this observation in the CEA database. This is not always a very meaningful field, because many times multiple proposals (and PIs) were given simultaneous data rights to the target in the same observing cycle. In that case, only one of the PIs is listed here. The observer is listed as "EUVE" for targets which were scheduled as calibration targets. However, for most calibration targets, there was also a PI to whom the data was proprietary; unfortunately, our archive does not contain these PI names for calibration targets.

Old Filename

Old EUVE Archive ID number (gonum): this is the old ID number the target was assigned in the now obsolete EUVE spectral browser and archive. Notice that there is not a one-to-one correspondence between the old archive and the new one, so some targets have more than one ID number associated with them and other IDs are used by multiple targets. The old ID might be of use for historical purposes or for users who know the old ID of a target they want. EUVE has stopped assigning ID numbers to publically released targets as of the Feb. 1, 1998 release.

Note wildcards can be used in the filename specification.

Public Date

This is the date on which an observation becomes public. If this field is blank, the target is already public. If there is a date present, the target is still proprietary to its Guest Observer and should not be made public until the indicated date. EUVE releases data on monthly intervals. Targets observed in Cycles 1-4 of the EUVE Guest Observer program have one year proprietary periods. In Cycle 5 (which began in 1997) and later, the period is six months. The period begins when the data is delivered, not when it was observed, and we sometimes make exceptions if there was a problem with the data delivery, etc., so the public dates cannot be inferred from the data itself. Also, some EUVE observations are done in parts over an extended period of time; the proprietary period is determined from the delivery date of the last part.

Output Columns

Your choice of what columns you want to see in the output. There are two radio buttons that let you select either the default set of columns, or choose your own set of columns.

The default set of columns for raw data sets is (in the order displayed):

```
Object Name
Observation Date
Day/Night
RA (J2000)
Dec (J2000)
Exposure Time
Observer
TOtal Size
Object Category
Spectral Type
Old Filename
Release Date
More info
```

You can select your own output columns by pressing the `custom...` radio button and selecting the columns from the list below it. The output columns will be in the order in which they appear in this list.

Sort output by:

Choose how you want the output rows sorted. You can select up to three fields to sort on. the rows will be sorted in the order of the first sort field; if two rows have the same sort field, they will be sorted in order of the second sort field, and so on.

For each field, you can select that the rows be sorted in *reverse* order on that field by selecting the `reverse` checkbox. For example, you can sort the rows with the most recent observations first by selecting `Observation Date` for the first sort field and selecting the `reverse` checkbox next to it.

Maximum number of hits

Some queries will be capable of returning hundreds of rows or more. Such large search results tend to use up memory on both the client and server sides, and aren't usually useful. By default, we limit the number of rows displayed to 100 rows, but you can increase (or decrease) this limit as needed.

Output equinox

Just what you'd think: the equinox of the coordinates displayed in the output.

Show SQL Query

Select this checkbox if you want to see the SQL query that the EUVE Search engine constructs from your query qualifications. The query will be shown at the end of the search results.

SQL (Standard Query Language, pronounced either "ess cue ell" or "sequel") is a language used used by most relational database systems for retrieving information from database tables. The EUVE Search Page takes your search specifications and converts them to an SQL query to run on our database. Viewing the generated query is often useful for debugging, and may also be useful for SQL-literate users who want to see what logic was used in the query. (In fact, this may be useful for most people, since SQL is pretty easy to understand.)

Search Help

There are two search pages for Copernicus data: the Raw Data Search page and the Coadded Scan Search page. Since most of the search fields are identical on the two pages, this help page applies to both.

The search pages basically contain 3 parts. The top of the page lists the input search fields. Entering values (as described below) for one or more of these fields will define the selection criteria for the database search. The middle of the form contains buttons to initiate various actions including:

1. perform the search using the specified search criteria and output format,
2. clear the search form and reset values to the original defaults,
3. reset entries to the set of (default) values used the previous time the search page was drawn, and
4. display this help page.

The bottom portion of the page deals with formatting the table of found entries that appears after the search is completed. The format options include specifying which columns appear in the output list, the order of the entries, the maximum number of returned entries, the epoch of the output coordinates, and the option to display the actual SQL command used to retrieve the database entries. First time users may want to run the search using the default output options.

After selecting search criteria, output options, and clicking the search button, a second page will appear listing the returned database entries. From this table, one may click on the object name to either display the FITS header for a raw data search, or display a plot of coadded counts versus wavelength for a coadded scan search. Clicking on the filenames for either catalog will download the selected FITS file.

Object Name

The name of the astronomical object you want to search for. Examples of valid names include ZETA OPH, JUPITER, and HD 14633. The object names were obtained from the Princeton University Observatory, presumably as specified by the observer.

When you search on the object name in the database, case will be ignored. The object name will *not* be wildcarded at the front and back (that's so if you innocently enter `IO`, you don't match things like `ORION`). You can wildcard the object name using `*`, however (for example, `*IO*`). You can also enter a comma-separated list; for example, `*JUP*,*SAT*` would match object names containing either `JUP` or `SAT`.

Object Resolver

The name resolver will let you resolve an object name into its coordinates. This is useful particularly for searching for objects that may be known by different names. You can resolve an object name either before a search, or you can redraw the form with the the resolved coordinates in place. If you don't elect to to resolve the object name, the Copernicus database will be searched on the object name given.

To resolve an object name before a search, enter the object name in the **Object Name** field, select `SIMBAD` for the resolver, and hit the **Search** button. SIMBAD is the Set of Identifications, Measurements, and Bibliography for Astronomical Data at the Centre de Données astronomiques in Strasbourg, France.) The object name will be sent to SIMBAD, which will send back the coordinates. (If the object name is not recognized by the resolver, or there is some other problem with the SIMBAD service, then the search form will be redrawn with an error message at the top.) These coordinates will then be used to search the Copernicus database, along with whatever other query qualifications you have given.

You can also hit the **Resolve** button instead of the **Search** button. In that case, the search form will be redrawn with the object's right ascension and declination entered as defaults in the **RA** and **Dec** fields. Resolving an object name will not change any other choices made in the form, except for the equinox, which will be reset to J2000 (since the SIMBAD resolver returns J2000 coordinates).

We recommend that you use object name resolution to find observations of specific object in the database. This is the most reliable way to look up observations, because the observer could have given any object name at all (for example, `NGC1976` instead of `M42`). However, if you do know the object name that the observer used, you can select `Don't resolve`, in which case the object name will not be resolved into coordinates, but will be used as a search qualification in the database. (This will happen only when you press the **Search** button.)

Resolve

When you press this button and select `SIMBAD` for the resolver, the Copernicus Search form will be redrawn with the coordinates for the given object entered into the RA and Dec fields. If you then press **Search**, the search will be conducted on that position. (The resolver will *not* be re-run for the search, unless you change either the object name or the resolver).

RA, Dec

The Right Ascension and Declination around which you want to search. A number of formats are accepted for the RA and Dec. Here are some examples:

```
Decimal Degrees
    185.63325 29.8959861111111

Hours, minutes and Seconds
    12 22 31.98      29 53 45.55
    12h22m31.98s     29d53m45.55s
    12:22:31.98     +29:53:45.55
    12h22'31.98"     29d53'45.55"
    12h 22m 31.98s   29d 53m 45.55s
    12h 22' 31.98"   29d 53' 45.55"
    12h 22' 31.98"  -29d 53' 45.55"
    12h22'31".98    -29d53'45".55
    12h22m31s.98    -29o53m45s.55
    12h 22' 31".98  -29d 53' 45".55

Hours/Degrees and Minutes (no seconds)
    12 22     29 53
    12h22m   +29d53m
    12h22m    29d53m
    12:22m    29:53m
    12h22'    29d53'
    12h 22m   29d 53m
    12h 22'   29d 53'
    12h 22'  -29d 53'

The RA may be given in decimal degrees by indicating
a D or d after the degrees:
    12d 22m   29d 53m
```

Spacing is not important, as long as the value is unambiguous, and that you delimit the hours/degrees, minutes, and (optional) seconds with letters, colons, spaces, or any character that's not a digit or a decimal point.

Note also that seconds of the form 31".98 or 31s.98 are accepted. This should make it easy to cut and paste values into these fields from electronic publications.

Radius

The radius of the search box around the RA and Dec, in floating-point arcminutes (e.g., `5.0`). You should be careful about giving too restrictive a search radius in an Copernicus search. Note most of the coordinates contained in the Copernicus catalog were obtained from the Bright Star Catalog (BSC5).

Equinox

The equinox of the RA and Dec you have entered, either `B1950` or `J2000`. This only affects the input coordinates; there is a separate selector for the equinox of the output coordinates.

If you hit the **Resolve** button to get an object's coordinates and redraw the form, the equinox will be set to `J2000`, since that's the equinox of the coordinates returned by the object name resolvers.

Start Date

The date and time, in GMT, on which the first exposure of a coadded scan was started. More precisely, it is the time in which the satellite crosses the longitude of the ascending node (LAN) for the orbit in which the earliest exposure was taken. (The actual start time is obtained by adding the FIRST SET time to the OBSERVATION TIME entry as described in **Observation Time Correction** .) The Copernicus satellite operated roughly from August, 1972 to February, 1981.

When specifying this date, you need to include at least a date; a time is optional. The date can have any of the following formats (the month name can be spelled out or abbreviated to three letters; case is not significant):

```
Jul 15 1994
Jul 1994 15
15 Jul 1994
1994 Jul 15
1994 15 Jul
7/15/1994
7-15-1994
7.15.1994
```

If the day is omitted, the first day of the month is assumed. This means that a specification like "July 1994" will look for observations done on July 1 1994 00:00:00, *not* for observations done during July 1994. Note also that when entering a date with the month in numerical format, the American ordering is used; i.e., the first number is the month.

If a time is omitted, then any time for that day will match. Otherwise, you can specify a time in any of these formats:

```
14:30
14:30:20
14:30:20:999
14:30:20.9
4am
4 PM
04:30:20 AM
```

To search for observations before a given date, use <, and for observations after a given date, use >. For example,

```
> Jul 15 1994
< Jul 15 1994
```

You can use the .. operator to search on a range of dates:

```
Jul 1 1994 .. Aug 1 1995
```

This operator is inclusive on the first date and exclusive on the second.

Finally, you can search on a list of dates or date ranges. For example,

```
Jul 1 1994 .. Jul 3 1994, Dec 1 1995 .. Dec 6 1995
```

will search for observations done within either one of these date ranges.

IUE_Class

IUE Object class code. The IUE classification system used for categorizing Copernicus observations. The object class was originally specified by the IUE Guest Observer. Only those object classes appropriate for Copernicus observations are listed (i.e., classes 1 through 83). Note more than one object class can be specified for the search by clicking on multiple entries from the object class table.

Min Wave

The minimum wavelength in the coadded scan, specified in Angstroms. Note coadded scan wavelengths are resampled to 0.01 Angstrom intervals.

Max Wave

The maximum wavelength contained in the coadded scan, specified in Angstroms. Note coadded scans are resampled to 0.01 Angstrom intervals.

Detector

Coadded scans have been generated for the U1 and U2 detectors. The U1 detector covers the 710-1500 A range at 0.05 A resolution, while U2 covers 750-1645 A at 0.2 A resolution.

Note the raw data sets contain data for all six detectors (i.e., u1,u2,u3,v1,v2,v3). V1 and V2 cover roughly the 1550-3200 A region at 0.1 and 0.4 A resolution respectively, while U3 and V3 are fixed in wavelength and used only for monitoring spacecraft pointing.

Spectral_Type

The spectral type of the observed star as derived from the Yale Bright Star Catalog (YBS5). Generally the spectral type is a measure of the star's temperature. Spectral type is designated using the Morgan-Keenan spectral classification system, and is specified as one of ten letters (OBAFGKMRNS) followed by a number from 0 to 9 designating subdivisions. The hottest stars observed are generally around type O3. Only those spectral types found in the Copernicus catalog however, are listed in the seach page. Spectral type is not appropriate for non-stellar objects (e.g., galaxies, planets, etc.), so the field may be left blank. Note the returned catalog listing will display the full spectral classification including the spectral type and the luminosity class.

Filename

The assigned file name. The raw data sets file names use the naming convention Cnnn.PEP where nnn is the 3-digit observation number assigned by Princeton Observatory describing the order in which targets were observed (i.e., the first observed target is named C001.PEP and the last target is C558.PEP).

The coadded scan file names are defined as Cnnn-###.ext where ### is a 3-digit number describing the order in which the scans were coadded (i.e., the maximum is 297), and ext is either .uu1 for unblocked u1 scans, .bu1 for blocked u1 scans, or .u2 for u2 scans.

Note wildcards can be used in the filename specification.

Output Columns

Your choice of what columns you want to see in the output. There are two radio buttons that let you select either the default set of columns, or choose your own set of columns.

The default set of columns for raw data sets is (in the order displayed):

```
Object Name
RA (J2000)
Dec (J2000)
Filename
scans
Spectral Class
IUE Class
More info
```

The default set of columns for coadded scans files is (in the order displayed):

```
Object Name
Detector
Filename
Min Wave
Max Wave
Start Date
RA (J2000)
Dec (J2000)
Object Class
Points
scans
Start Scan
Last Scan
```

You can select your own output columns by pressing the `custom...` radio button and selecting the columns from the list below it. The output columns will be in the order in which they appear in this list.

Sort output by:

Choose how you want the output rows sorted. You can select up to three fields to sort on. the rows will be sorted in the order of the first sort field; if two rows have the same sort field, they will be sorted in order of the second sort field, and so on.

For each field, you can select that the rows be sorted in *reverse* order on that field by selecting the `reverse` checkbox. For example, you can sort the rows with the most recent observations first by selecting `Observation Date` for the first sort field and selecting the `reverse` checkbox next to it.

Maximum number of hits

Some queries will be capable of returning thousands of rows or more. Such large search results tend to use up memory on both the client and server sides, and aren't usually useful. By default, we limit the number of rows displayed to 100 rows, but you can increase (or decrease) this limit as needed.

Output equinox

Just what you'd think: the equinox of the coordinates displayed in the output.

Show SQL Query

Select this checkbox if you want to see the SQL query that the Copernicus Search engine constructs from your query qualifications. The query will be shown at the end of the search results.

SQL (Standard Query Language, pronounced either "ess cue ell" or "sequel") is a language used used by most relational database systems for retrieving information from database tables. The Copernicus Search Page takes your search specifications and converts them to an SQL query to run on our database. Viewing the generated query is often useful for debugging, and may also be useful for SQL-literate users who want to see what logic was used in the query. (In fact, this may be useful for most people, since SQL is pretty easy to understand.)

Access to ROSAT catalogs and data are courtesy of HEASARC

ROSAT Search & Retrieval Help

This page describes the parameters for MAST's ROSAT search form which are sent to HEASARC's HEASARC ROSAT master catalog (ROSMASTER).

More information is available about the MAST/HEASARC query syntax.

Fields for Data Search

ROR
The ROSAT observation request sequence number.

Object Name
The name of the target, as given by the PI.

Resolver
The name resolver to use. Either SIMBAD or NED may be used to get the coordinates of a target name. Alternatively, by selecting `Don't resolve`, you can use match the target name against that given by the PI. (Note: Since observer-chosen target names can vary wildly, it is in general better to search on a position for fixed targets. Searching on a target name without resolving should be used only for moving objects and when you know what the observer called the target.)

Radius
The search radius, in arcminutes.

PI_Number
The Principal Investigator number.

R_Day_Beg
The ROSAT day number at the start of the pointing. ROSAT Day #1 was June 2, 1990. ROSAT day numbers between 1 and 60 are from the performance verification (PV) phase, while day numbers greater than about 256 are from the AO1 phase.

R_Day_End
The ROSAT day number at the end of the pointing. ROSAT Day #1 was June 2, 1990. ROSAT day numbers between 1 and 60 are from the performance verification (PV) phase, while day numbers greater than ~256 are from the AO1 phase.

Exposure
The exposure time of the pointing, in seconds. **PLEASE NOTE** The `exposure` shown here indicates only the length of time that the telescope pointed in a certain direction; it is *not* a total observation time. Operational or other problems may have occurred during the pointing which could cause the total observation time to be less than the `exposure` given here.

Instrument
The instrument used for the pointing, either `HRI` or `PSPC`.

Status
The Status of the observation. Valid values of status are `distributed`, `ob_completed`, `ob_running`, `ob_scheduled`, and `public`.

Complete
Completion flag. `T` is complete, `F` is incomplete.

Priority
The priorty of the observation: `A`, `B`, or `C`.

Roll
The roll angle of the spacecraft during the pointing.

Observation Number
The observation number.

Begin Date
The date at the beginning of the observation. This field contains only the date (i.e., the Modifed Julian Day number), not the time. See the syntax help page for information about how to qualify date fields for data held at HEASARC.

End Date
The date at the end of the observation. This field contains only the date (i.e., the Modifed Julian Day number), not the time. See the syntax help page for information about how to qualify date fields for data held at HEASARC.

Begin Second
The seconds of the day at the beginning of the observation.

End Second
The seconds of the day at the end of the observation.

SC Begin
The spacecraft clock at the beginning of the observation.

SC End
The spacecraft clock at the end of the observation.

Cycle
The annual cycle of the observation (0-7).

Proposal Number
The number correspondant to a given proposal.

Time Req
The requested time of the observation. (ksec)

Time Done
The time completed. (ksec)

ra
Right ascension in default equinox.

dec
Declination in default equinox.

RA_J2000
The average MEASURED right ascension of the pointing in J2000 coordinates.

Dec_J2000
The average MEASURED declination of the pointing in J2000 coordinates.

Gal Lat
Galactic longitude.

Gal Lon
Galactic latitude.

Targ Num
The target number.

Country
The originating country for this ROSAT Observation Request.

RDay Begin
ROSAT day number at the beginning of the pointing.

RDay End
ROSAT day number at the end of the pointing.

Category
The major catagory of the object observed. More than one category may be selected.
Note: Object categories should be used with care. The assignment of categories themselves is more of an art than a science. Also, the categories are those of the object that the PI was interested in. For example, selecting `Normal Stars` will not show all observations in which a normal star appears serendipitously (which would be jsut about all ROSAT observations).

class
BROWSE classification flag. The value of this field is always `UNIDENTIFIED`.

Site
The location at which the data was processed, either `MPE` or `GSFC`.

Rev
The processing revision number of the sequence.

Distribution Date
The data distribution date. This field contains only the date (i.e., the Modifed Julian Day number), not the time. See the MAST/HEASARC Syntax page for information about how to qualify date fields.

Release Date
The date on which the data were made publicly available. HEASARC distributes only public data. This field contains only the date (i.e., the Modifed Julian Day number), not the time. See the MAST/HEASARC Syntax page for information about how to qualify date fields.

Seq ID
The sequence identification number (i.e. `rp123456n00`).

PI Last Name
The last name of the Principal Investigator for the ROSAT Observation Request associated with this pointing.

PI First Name
The first name of the Principal Investigator for the ROSAT Observation Request associated with this pointing.

Retrievals

ROSAT data may be retrieved from HEASARC through the MAST's retrieval forms. After executing a search, a results page will be presented. At the bottom of the page a selection of retrieval options will be presented. You can list the available data for selected datasets, then download your choices file by file, or you may elect to build a single tar file containing all the selected files. After you make your selections and click on "submit," a separate browser window will pop up on HEASARC's retrieval pages.

HUT Archive Status

Data from the Hopkins Ultraviolet Telescope (HUT) is currently kept on magnetic disk at STScI, so there shouldn't be a long wait or much downtime.

HUT Search Help

Use the HUT Search form to search the HUT Catalog by object name, position, observation date, etc. and to specify the output format. You can then view preview data and mark data for retrieval using this interface.

Object Name

The name of the astronomical object you want to search for. Examples of valid names include GAM-GEM, NGC1068, JUPITER, and HD45677. (Note no spaces are used in HUT target names.)

When you search on the object name in the database, case will be ignored. The object name will *not* be wildcarded at the front and back (that's so if you innocently enter `IO`, you don't match things like `ORION`). You can wildcard the object name using `*`, however (for example, `*1987*`). You can also enter a comma-separated list; for example, `*JUP*,*SAT*` would match object names containing either `JUP` or `SAT`.

Object Resolver

The name resolver will let you resolve an object name into its coordinates. This is useful particularly for searching for objects that may be known by different names. You can resolve an object name either before a search, or you can redraw the form with the resolved coordinates in place. If you don't elect to resolve the object name, the HUT database will be searched on the object name given.

The SIMBAD and NED object name resolvers can resolve only fixed objects; they cannot compute the positions of moving objects (planets, comets, etc.). To find moving objects, try selecting the appropriate object class, entering an object name that could match what you're looking for, and selecting `Don't resolve` for the name resolver. NED is an extragalactic database, and generally won't resolve object names within the Milky Way galaxy.

To resolve an object name before a search, enter the object name in the **Object Name** field, select either `SIMBAD` or `NED` for the resolver, and hit the **Search** button. (NED is the Nasa Extragalactic Database at Caltech in Pasadena, California, and SIMBAD is the Set of Identifications, Measurements, and Bibliography for Astronomical Data at the Centre de Données astronomiques in Strasbourg, France.) The object name will be sent to SIMBAD, which will send back the coordinates. (If the object name is not recognized by the resolver, or there is some other problem with the SIMBAD service, then the search form will be redrawn with an error message at the top.) These coordinates will then be used to search the HUT database, along with whatever other query qualifications you have given.

You can also hit the **Resolve** button instead of the **Search** button. In that case, the search form will be redrawn with the object's right ascension and declination entered as defaults in the **RA** and **Dec** fields. Resolving an object name will not change any other choices made in the form, except for the equinox, which will be reset to J2000 (since the SIMBAD resolver returns J2000 coordinates).

We recommend that you use object name resolution to find observations of specific objects in the database. This is the most reliable way to look up observations, because the observer could have given any object name at all (for example, `NGC1976` instead of `M42`). However, if you do know the object name that the observer used, you can select `Don't resolve`, in which case the object name will not be resolved into coordinates, but will be used as a search qualification in the database. (This will happen only when you press the **Search** button.)

Resolve

When you press this button and select `SIMBAD` for the resolver, the HUT Search form will be redrawn with the coordinates for the given object entered into the RA and Dec fields. If you then press **Search**, the search will be conducted on that position. (The resolver will *not* be re-run for the search, unless you change either the object name or the resolver).

RA, Dec

The Right Ascension and Declination around which you want to search. These fields give the J2000 equatorial coordinates for the center of the image. A number of formats are accepted for the RA and Dec. Here are some examples:

```
Decimal Degrees
    185.63325 29.8959861111111

Hours, minutes and Seconds
    12 22 31.98      29 53 45.55
    12h22m31.98s     29d53m45.55s
    12:22:31.98     +29:53:45.55
    12h22'31.98"     29d53'45.55"
    12h 22m 31.98s   29d 53m 45.55s
    12h 22' 31.98"   29d 53' 45.55"
    12h 22' 31.98"  -29d 53' 45.55"
    12h22'31".98    -29d53'45".55
    12h22m31s.98    -29o53m45s.55
    12h 22' 31".98  -29d 53' 45".55

Hours/Degrees and Minutes (no seconds)
    12 22     29 53
    12h22m   +29d53m
    12h22m    29d53m
    12:22m    29:53m
    12h22'    29d53'
    12h 22m   29d 53m
    12h 22'   29d 53'
    12h 22'  -29d 53'

The RA may be given in decimal degrees by
indicating a D or d after the degrees:
    12d 22m   29d 53m
```

Spacing is not important, as long as the value is unambiguous, and that you delimit the hours/degrees, minutes, and (optional) seconds with letters, colons, spaces, or any character that's not a digit or a decimal point.

Note also that seconds of the form 31".98 or 31s.98 are accepted. This should make it easy to cut and paste values into these fields from electronic publications.

Radius

The radius of the search box around the RA and Dec, in floating-point arcminutes (e.g., `5.0`). You should be careful about giving too restrictive a search radius in an HUT search.

Equinox

The equinox of the RA and Dec you have entered, either `B1950` or `J2000`. This only affects the input coordinates; there is a separate selector for the equinox of the output coordinates.

If you hit the **Resolve** button to get an object's coordinates and redraw the form, the equinox will be set to `J2000`, since that's the equinox of the coordinates returned by the object name resolvers.

Object Category

This is a broad category for the target. One or more values may be selected. Clicking "reset to defaults" or "clear form" (described below) will erase previous selections.

Observation Start Date

This is the GMT time, to the nearest second, of the start of the observation. (Note the HUT1 observations were all obtained during December 2-10, 1990 and HUT2 observations were obtained during March 2-18, 1995.)

When specifying this date, you need to include at least a date; a time is optional. The date can have any of the following formats (the month name can be spelled out or abbreviated to three letters; case is not significant):

```
Dec 15 1990
Dec 1990 15
15 Dec 1990
1990 Dec 15
1990 15 Dec
7/15/1990
7-15-1990
7.15.1990
```

If the day is omitted, the first day of the month is assumed. This means that a specification like "Dec 1990" will look for observations done on Dec 1 1990 00:00:00, *not* for observations done during Decy 1990. Note also that when entering a date with the month in numerical format, the American ordering is used; i.e., the first number is the month.

If a time is omitted, then any time for that day will match. Otherwise, you can specify a time in any of these formats:

```
14:30
14:30:20
14:30:20:999
14:30:20.9
4am
4 PM
04:30:20 AM
```

To search for observations before a given date, use <, and for observations after a given date, use >. For example,

```
> Dec 10 1990
< Dec 10 1990
```

You can use the .. operator to search on a range of dates:

```
Mar 2 1995 .. Mar 5 1995
```

This operator is inclusive on the first date and exclusive on the second.

Finally, you can search on a list of dates or date ranges. For example,

```
Mar 10 1995 .. Mar 11 1995,
Mar 15 1995 .. Mar 16 1995
```

will search for observations done within either one of these date ranges.

Exposure Time

The total exposure times in seconds. Note the times do not reflect pointing problems. In many cases, the target was not in the aperture.

Entry ID

The HUT entry_id uniquely defines each HUT observation. The name is of the form **object_id-nnn** where

- **object-id** = the target name
- **nnn** = a unique three-digit number based on the Mission Elapsed Time (MET) in tenths of hours.

As an example, entry_id P-CYG_087 designates a P Cygni observation taken 8.7 hours into the mission.

Note that for each observation, several data sets may be produced representing different stages of processing.

Output Columns

Your choice of what columns you want to see in the output. There are two radio buttons that let you select either the default set of columns, or choose your own set of columns.

The default set of columns for raw data sets is (in the order displayed):

```
Object Name
RA (J2000)
Dec (J2000)
Observation Date
Exposure Time
Daytime
Nighttime
```

```
Object Category
Comments
Entry_ID
More info
```

You can select your own output columns by pressing the `custom...` radio button and selecting the columns from the list below it. The output columns will be in the order in which they appear in this list.

Sort output by:

Choose how you want the output rows sorted. You can select up to three fields to sort on. The rows will be sorted in the order of the first sort field; if two rows have the same sort field, they will be sorted in order of the second sort field, and so on.

For each field, you can select that the rows be sorted in *reverse* order on that field by selecting the `reverse` checkbox. For example, you can sort the rows with the most recent observations first by selecting `Observation Date` for the first sort field and selecting the `reverse` checkbox next to it.

Maximum number of hits

Some queries will be capable of returning hundreds of rows or more. Such large search results tend to use up memory on both the client and server sides, and aren't usually useful. By default, we limit the number of rows displayed to 100 rows, but you can increase (or decrease) this limit as needed.

Output equinox

Just what you'd think: the equinox of the coordinates displayed in the output.

Show SQL Query

Select this checkbox if you want to see the SQL query that the HUT Search engine constructs from your query qualifications. The query will be shown at the end of the search results.

SQL (Standard Query Language, pronounced either "ess cue ell" or "sequel") is a language used by most relational database systems for retrieving information from database tables. The HUT Search Page takes your search specifications and converts them to an SQL query to run on our database. Viewing the generated query is often useful for debugging, and may also be useful for SQL-literate users who want to see what logic was used in the query. (In fact, this may be useful for most people, since SQL is pretty easy to understand.)

Planned Archive Downtimes

These are scheduled downtimes which will affect access to the MAST CDROM jukeboxes. Note: Due to the nature of the archive systems, we cannot always report *un*scheduled downtimes.

No currently scheduled downtimes.

UIT Search Help

Use the UIT Search form to search the UIT Catalog by object name, position, observation date, filter, etc., and to specify the output format. You can then view preview data and mark data for retrieval using this interface.

Object Name

The name of the astronomical object you want to search for. Examples of valid names include AX-PER, NGC0185, MARS, and HD269810. (Note that no spaces are used in UIT target names.)

When you search on the object name in the database, case will be ignored. The object name will *not* be wildcarded at the front and back (that's so if you innocently enter `IO`, you don't match things like `ORION`). You can wildcard the object name using `*`, however (for example, `*IO*`). You can also enter a comma-separated list; for example, `*JUP*,*SAT*` would match object names containing either `JUP` or `SAT`.

Object Resolver

The name resolver will let you resolve an object name into its coordinates. This is useful particularly for searching for objects that may be known by different names. You can resolve an object name either before a search, or you can redraw the form with the resolved coordinates in place. If you don't elect to resolve the object name, the UIT database will be searched on the object name given.

The SIMBAD and NED object name resolvers can resolve only fixed objects; they cannot compute the positions of moving objects (planets, comets, etc.). To find moving objects, try selecting the appropriate object class, entering an object name that could match what you're looking for, and selecting `Don't resolve` for the name resolver. NED is an extragalactic database, and generally won't resolve object names within the Milky Way galaxy.

To resolve an object name before a search, enter the object name in the **Object Name** field, select either `SIMBAD` or `NED` for the resolver, and hit the **Search** button. (NED is the Nasa Extragalactic Database at Caltech in Pasadena, California, and SIMBAD is the Set of Identifications, Measurements, and Bibliography for Astronomical Data at the Centre de Données astronomiques in Strasbourg, France.) The object name will be sent to SIMBAD, which will send back the coordinates. (If the object name is not recognized by the resolver, or there is some other problem with the SIMBAD service, then the search form will be redrawn with an error message at the top.) These coordinates will then be used to search the UIT database, along with whatever other query qualifications you have given.

You can also hit the **Resolve** button instead of the **Search** button. In that case, the search form will be redrawn with the object's right ascension and declination entered as defaults in the **RA** and **Dec** fields. Resolving an object name will not change any other choices made in the form, except for the equinox, which will be reset to J2000 (since the SIMBAD resolver returns J2000 coordinates).

We recommend that you use object name resolution to find observations of specific objects in the database. This is the most reliable way to look up observations, because the observer could have given any object name at all (for example, `NGC1976` instead of `M42`). However, if you do know the object name that the observer used, you can select `Don't resolve`, in which case the object name will not be resolved into coordinates, but will be used as a search qualification in the database. (This will happen only when you press the **Search** button.)

Resolve

When you press this button and select `SIMBAD` for the resolver, the UIT Search form will be redrawn with the coordinates for the given object entered into the RA and Dec fields. If you then press **Search**, the search will be conducted on that position. (The resolver will *not* be re-run for the search, unless you change either the object name or the resolver).

The SIMBAD and NED object name resolvers can resolve only fixed objects; they cannot compute the positions of moving objects (planets, comets, etc.). To find moving objects, try selecting the appropriate object class, entering an object name that could match what you're looking for, and selecting `Don't resolve` for the name resolver. NED is an extragalactic database, and generally won't resolve object names within the Milky Way galaxy.

RA, Dec

The Right Ascension and Declination around which you want to search. These fields give the J2000 equatorial coordinates for the center of the image. A number of formats are accepted for the RA and Dec. Here are some examples:

```
Decimal Degrees
    185.63325 29.8959861111111

Hours, minutes and Seconds
    12 22 31.98       29 53 45.55
    12h22m31.98s      29d53m45.55s
    12:22:31.98      +29:53:45.55
    12h22'31.98"      29d53'45.55"
    12h 22m 31.98s    29d 53m 45.55s
    12h 22' 31.98"    29d 53' 45.55"
    12h 22' 31.98"   -29d 53' 45.55"
    12h22'31".98     -29d53'45".55
    12h22m31s.98     -29o53m45s.55
    12h 22' 31".98   -29d 53' 45".55

Hours/Degrees and Minutes (no seconds)
    12 22      29 53
    12h22m   +29d53m
    12h22m    29d53m
    12:22m    29:53m
    12h22'    29d53'
    12h 22m   29d 53m
    12h 22'   29d 53'
    12h 22'  -29d 53'

The RA may be given in decimal degrees by
indicating a D or d after the degrees:
    12d 22m   29d 53m
```

Spacing is not important, as long as the value is unambiguous, and that you delimit the hours/degrees, minutes, and (optional) seconds with letters, colons, spaces, or any character that's not a digit or a decimal point.

Note also that seconds of the form 31".98 or 31s.98 are accepted. This should make it easy to cut and paste values into these fields from electronic publications.

Radius

The radius of the search box around the RA and Dec, in floating-point arcminutes (e.g., `5.0`). You should be careful about giving too restrictive a search radius in an UIT search.

Equinox

The equinox of the RA and Dec you have entered, either `B1950` or `J2000`. This affects only the input coordinates; there is a separate selector for the equinox of the output coordinates.

If you hit the **Resolve** button to get an object's coordinates and redraw the form, the equinox will be set to `J2000`, since that's the equinox of the coordinates returned by the object name resolvers.

Object Category

This is a broad category for the target. One or more values may be selected. Clicking "reset to defaults" or "clear form" (described below) will erase previous selections.

Observation Start Date

This is the GMT time, to the nearest second, of the start of the observation. (Note the UIT1 observations were all obtained during December 2-10, 1990, and UIT2 observations were obtained during March 2-18, 1995.)

When specifying this date, you need to include at least a date; a time is optional. The date can have any of the following formats (the month name can be spelled out or abbreviated to three letters; case is not significant):

```
Dec 15 1990
Dec 1990 15
15 Dec 1990
1990 Dec 15
1990 15 Dec
7/15/1990
7-15-1990
7.15.1990
```

If the day is omitted, the first day of the month is assumed. This means that a specification like "Dec 1990" will look for observations done on Dec 1 1990 00:00:00, *not* for observations done during December 1990. Note also that when entering a date with the month in numerical format, the American ordering is used; i.e., the first number is the month.

If a time is omitted, then any time for that day will match. Otherwise, you can specify a time in any of these formats:

```
14:30
14:30:20
14:30:20:999
14:30:20.9
4am
4 PM
04:30:20 AM
```

To search for observations before a given date, use <, and for observations after a given date, use >. For example,

```
> Dec 10 1990
< Dec 10 1990
```

You can use the .. operator to search on a range of dates:

```
Mar 2 1995 .. Mar 5 1995
```

This operator is inclusive on the first date and exclusive on the second.

Finally, you can search on a list of dates or date ranges. For example,

```
Mar 10 1995 .. Mar 11 1995,
Mar 15 1995 .. Mar 16 1995
```

will search for observations done within either one of these date ranges.

Exposure Time

The exposure times annotated on the film by the Dedicated Experiment Processor (DEP) were found to be incorrect by known amounts. The corrected exposure times used in the batch data processing (BDR) are stored in the database and in the FITS headers using the keyword EXPTIME (uncorrected times are stored in the FITS header using the keyword FEXPTIME.)

The corrected exposure length was computed from

- (a) the exposure time written onto film (if it had no hex digits) plus 0.5 seconds, or
- (b) if the exposure time written onto film had hex digits (i.e., it was the first frame in the exposure sequence), then the value from the previous film frame was used after subtracting 0.3 seconds, or
- (c) telemetry plus 0.5 seconds.

Null entries imply a raw density image was obtained. The uncertainty in the corrected exposure times for the majority of exposures is of the order of 0.04 seconds (Stecker et al, PASP 109,584 1997).

Entry ID

The UIT entry_id uniquely defines each UIT observation. The name is of the form **CuvMnnn** where

- **C** = "N" for the near-UV camera (which failed during the ASTRO-2 mission), or "F" for the far-UV camera,
- **M** = "0" for ASTRO-1 data, "1" for ASTRO-2 data before a Dedicated Experiment Processor (DEP) memory change reset the frame counter, or "2" for ASTRO-2 data after the DEP memory change.
- **nnn** = a three-digit number designating the order in which the UIT observations were obtained for a particular camera.

As an example, entry_id FUV2349 designates the 349th exposure with the Far-UV camera during the ASTRO-2 mission.

Note that for each observation, several data sets may be produced representing different stages of processing. The final linearized, undistorted data set may be stored using a file name such as fuv2349g.fits.

Filter

The UIT instrument included two six-position filter wheels. The "A" filters were sensitive in the near-UV while the "B" filters were sensitive in the Far-UV. The near-UV camera was operational only for the ASTRO-1 flight. The effective wavelengths and FWHM's are listed on the Instrument page.

Output Columns

Your choice of what columns you want to see in the output. There are two radio buttons that let you select either the default set of columns, or choose your own set of columns.

The default set of columns for raw data sets is (in the order displayed):

```
Object Name
RA (J2000)
Dec (J2000)
Entry_ID
Observation Date
Exposure Time
Object Category
Filter
More info
```

You can select your own output columns by pressing the `custom...` radio button and selecting the columns from the list below it. The output columns will be in the order in which they appear in this list.

Sort output by:

Choose how you want the output rows sorted. You can select up to three fields to sort on. The rows will be sorted in the order of the first sort field; if two rows have the same sort field, they will be sorted in order of the second sort field, and so on.

For each field, you can select that the rows be sorted in *reverse* order on that field by selecting the `reverse` checkbox. For example, you can sort the rows with the most recent observations first by selecting `Observation Date` for the first sort field and selecting the `reverse` checkbox next to it.

Maximum number of hits

Some queries will be capable of returning hundreds of rows or more. Such large search results tend to use up memory on both the client and server sides, and aren't usually useful. By default, we limit the number of rows displayed to 100 rows, but you can increase (or decrease) this limit as needed.

Output equinox

Just what you'd think: the equinox of the coordinates displayed in the output.

Show SQL Query

Select this checkbox if you want to see the SQL query that the UIT Search engine constructs from your query qualifications. The query will be shown at the end of the search results.

SQL (Standard Query Language, pronounced either "ess cue ell" or "sequel") is a language used by most relational database systems for retrieving information from database tables. The UIT Search Page takes your search specifications and converts them to an SQL query to run on our database. Viewing the generated query is often useful for debugging, and may also be useful for SQL-literate users who want to see what logic was used in the query. (In fact, this may be useful for most people, since SQL is pretty easy to understand.)

WUPPE Search Help

Use the WUPPE Search form to search the WUPPE Catalog by object name, position, observation date, etc., and to specify the output format. You can then view preview data and mark data for retrieval using this interface.

Object Name

The name of the astronomical object you want to search for. Examples of valid names include GAM-GEM, NGC1068, JUPITER, and HD45677. (Note no spaces are used in WUPPE target names.)

When you search on the object name in the database, case will be ignored. The object name will *not* be wildcarded at the front and back (that's so if you innocently enter `IO`, you don't match things like `ORION`). You can wildcard the object name using `*`, however (for example, `*1987*`). You can also enter a comma-separated list; for example, `*JUP*,*SAT*` would match object names containing either `JUP` or `SAT`.

Object Resolver

The name resolver will let you resolve an object name into its coordinates. This is useful particularly for searching for objects that may be known by different names. You can resolve an object name either before a search, or you can redraw the form with the resolved coordinates in place. If you don't elect to resolve the object name, the WUPPE database will be searched on the object name given.

The SIMBAD and NED object name resolvers can resolve only fixed objects; they cannot compute the positions of moving objects (planets, comets, etc.). To find moving objects, try selecting the appropriate object class, entering an object name that could match what you're looking for, and selecting `Don't resolve` for the name resolver. NED is an extragalactic database, and generally won't resolve object names within the Milky Way galaxy.

To resolve an object name before a search, enter the object name in the **Object Name** field, select either `SIMBAD` or `NED` for the resolver, and hit the **Search** button. (NED is the Nasa Extragalactic Database at Caltech in Pasadena, California, and SIMBAD is the Set of Identifications, Measurements, and Bibliography for Astronomical Data at the Centre de Données astronomiques in Strasbourg, France.) The object name will be sent to SIMBAD, which will send back the coordinates. (If the object name is not recognized by the resolver, or there is some other problem with the SIMBAD service, then the search form will be redrawn with an error message at the top.) These coordinates will then be used to search the WUPPE database, along with whatever other query qualifications you have given.

You can also hit the **Resolve** button instead of the **Search** button. In that case, the search form will be redrawn with the object's right ascension and declination entered as defaults in the **RA** and **Dec** fields. Resolving an object name will not change any other choices made in the form, except for the equinox, which will be reset to J2000 (since the SIMBAD resolver returns J2000 coordinates).

We recommend that you use object name resolution to find observations of specific objects in the database. This is the most reliable way to look up observations, because the observer could have given any object name at all (for example, `NGC1976` instead of `M42`). However, if you do know the object name that the observer used, you can select `Don't resolve`, in which case the object name will not be resolved into coordinates, but will be used as a search qualification in the database. (This will happen only when you press the **Search** button.)

Resolve

When you press this button and select `SIMBAD` for the resolver, the WUPPE Search form will be redrawn with the coordinates for the given object entered into the RA and Dec fields. If you then press **Search**, the search will be conducted on that position. (The resolver will *not* be re-run for the search, unless you change either the object name or the resolver).

RA, Dec

The Right Ascension and Declination around which you want to search. These fields give the J2000 equatorial coordinates for the center of the image. A number of formats are accepted for the RA and Dec. Here are some examples:

```
Decimal Degrees
    185.63325 29.8959861111111

Hours, minutes and Seconds
    12 22 31.98      29 53 45.55
    12h22m31.98s     29d53m45.55s
    12:22:31.98     +29:53:45.55
    12h22'31.98"     29d53'45.55"
    12h 22m 31.98s   29d 53m 45.55s
    12h 22' 31.98"   29d 53' 45.55"
    12h 22' 31.98"  -29d 53' 45.55"
    12h22'31".98    -29d53'45".55
    12h22m31s.98    -29o53m45s.55
    12h 22' 31".98  -29d 53' 45".55

Hours/Degrees and Minutes (no seconds)
    12 22     29 53
    12h22m   +29d53m
    12h22m    29d53m
    12:22m    29:53m
    12h22'    29d53'
    12h 22m   29d 53m
    12h 22'   29d 53'
    12h 22'  -29d 53'

The RA may be given in decimal degrees by
indicating a D or d after the degrees:
    12d 22m   29d 53m
```

Spacing is not important, as long as the value is unambiguous, and that you delimit the hours/degrees, minutes, and (optional) seconds with letters, colons, spaces, or any character that's not a digit or a decimal point.

Note also that seconds of the form 31".98 or 31s.98 are accepted. This should make it easy to cut and paste values into these fields from electronic publications.

Radius

The radius of the search box around the RA and Dec, in floating-point arcminutes (e.g., `5.0`). You should be careful about giving too restrictive a search radius in an WUPPE search.

Equinox

The equinox of the RA and Dec you have entered, either `B1950` or `J2000`. This only affects the input coordinates; there is a separate selector for the equinox of the output coordinates.

If you hit the **Resolve** button to get an object's coordinates and redraw the form, the equinox will be set to `J2000`, since that's the equinox of the coordinates returned by the object name resolvers.

Object Category

This is a broad target category also known as the ASTRO Science Classes. The categories were choosen by the project and used for all the ASTRO instruments (i.e., HUT, UIT, and WUPPE). Categories for which no data is available have been removed from the selection. One or more categories may be selected for the search. Clicking "reset to defaults" or "clear form" (described below) will erase previous selections.

Observation Start Date

This is the GMT time, to the nearest second, of the start of the observation. (Note the WUPPE1 observations were all obtained during December 2-10, 1990 and WUPPE2 observations were obtained during March 2-18, 1995.)

When specifying this date, you need to include at least a date; a time is optional. The date can have any of the following formats (the month name can be spelled out or abbreviated to three letters; case is not significant):

```
Dec 15 1990
Dec 1990 15
15 Dec 1990
1990 Dec 15
1990 15 Dec
7/15/1990
7-15-1990
7.15.1990
```

If the day is omitted, the first day of the month is assumed. This means that a specification like "Dec 1990" will look for observations done on Dec 1 1990 00:00:00, *not* for observations done during Decy 1990. Note also that when entering a date with the month in numerical format, the American ordering is used; i.e., the first number is the month.

If a time is omitted, then any time for that day will match. Otherwise, you can specify a time in any of these formats:

```
14:30
14:30:20
14:30:20:999
14:30:20.9
4am
4 PM
04:30:20 AM
```

To search for observations before a given date, use <, and for observations after a given date, use >. For example,

```
> Dec 10 1990
< Dec 10 1990
```

You can use the .. operator to search on a range of dates:

```
Mar 2 1995 .. Mar 5 1995
```

This operator is inclusive on the first date and exclusive on the second.

Finally, you can search on a list of dates or date ranges. For example,

```
Mar 10 1995 .. Mar 11 1995,
Mar 15 1995 .. Mar 16 1995
```

will search for observations done within either one of these date ranges.

Exposure Time

The total useable exposure times in seconds.

Entry ID

The WUPPE entry_id uniquely defines each WUPPE observation. The name is of the form **MISSION-OBJECTID-nnnnnn** where

- **MISSION** = either WUPPE1 or WUPPE2
- **OBJECTID** = object name (e.g., GAM-GEM or NGC4151), identical to the entries under "Target Name",
- **nnnnnn** = a unique six-digit number (also known as the PointingID), based on the 2-digit ASTRO Science Class, a 2-digit preassigned target number for a given science class (although some targets have more than one target number), and a 2-digit pointing number (i.e., jotfid) for a particular target. The first digit of the pointing number is a sequential number indicating the nth observation at a particular roll angle, and the second digit is the nth exposure at that roll angle.

As an example, entry_id WUPPE1_HD5980_226911 designates an observation of HD5980, which is in science class 22, was the 69th selected target in class 22, the first observation at a given roll angle, and the first observation at that roll angle. Within the ASTRO project, the number 226911 would be referred to as the PointingID and the jotfid is 11.

Wild cards may be used for searching by entry_id. For example, to find all observations of HD5980, specify *HD5980*. To see all the WUPPE1 entries, search on WUPPE1*.

Note that for each observation, several data sets may be produced representing different stages of processing.

Output Columns

Your choice of what columns you want to see in the output. There are two radio buttons that let you select either the default set of columns, or choose your own set of columns.

The entire set of columns, with the default items marked with a "*", includes the following (in the order displayed):

```
* Object Name
* RA (J2000)
* Dec (J2000)
* Mean % Polarization
* Mean Error in % Polarization
* Polarizarion Position Angle
* Observation Date
* Exposure Time
* Object Category
* Comments
* Mission
  References
  Aperture
  Day/Night flag
  Filter
  Spectral Type
  Visual magnitude
  Polarization Quality
  Flux Quality
  Image Motion Compensation
  MET Start Time
  Prime
* Entry_ID
* More info
```

NOTE: If the % Polarization, % Error, and Pos Angle are all set to 0.000, the dataset does not include any polarization data, only the UV spectrum.

You can select your own output columns by pressing the `custom...` radio button and selecting the columns from the list below it. The output columns will be in the order in which they appear in this list. (Note the default set will be included in custom mode unless they are deselected.)

Sort output by:

Choose how you want the output rows sorted. You can select up to three fields to sort on. The rows will be sorted in the order of the first sort field; if two rows have the same sort field, they will be sorted in order of the second sort field, and so on.

For each field, you can select that the rows be sorted in *reverse* order on that field by selecting the `reverse` checkbox. For example, you can sort the rows with the most recent observations first by selecting `Observation Date` for the first sort field and selecting the `reverse` checkbox next to it.

Maximum number of hits

Some queries will be capable of returning hundreds of rows or more. Such large search results tend to use up memory on both the client and server sides, and aren't usually useful. By default, we limit the number of rows displayed to 100 rows, but you can increase (or decrease) this limit as needed.

Output equinox

Just what you'd think: the equinox of the coordinates displayed in the output.

Show SQL Query

Select this checkbox if you want to see the SQL query that the WUPPE Search engine constructs from your query qualifications. The query will be shown at the end of the search results.

SQL (Standard Query Language, pronounced either "ess cue ell" or "sequel") is a language used by most relational database systems for retrieving information from database tables. The WUPPE Search Page takes your search specifications and converts them to an SQL query to run on our database. Viewing the generated query is often useful for debugging, and may also be useful for SQL-literate users who want to see what logic was used in the query. (In fact, this may be useful for most people, since SQL is pretty easy to understand.)

BEFS Search Help

The MAST search pages basically contain three parts. The top of the page lists the input search fields. Entering values (as described below) for one or more of these fields will define the selection criteria for the database search. The middle of the form contains buttons to initiate various actions including:

1. perform the search using the specified search criteria and output format,
2. clear the search form and reset values to the original defaults,
3. reset entries to the set of (default) values used the previous time the search page was drawn, and
4. display this help page.

The bottom portion of the page deals with formatting the table of found entries that appears after the search is completed. The format options include specifying which columns appear in the output list, the order of the entries, the maximum number of returned entries, the epoch of the output coordinates, and the option to display the actual SQL command used to retrieve the database entries. First time users may want to run the search using the default output options.

After selecting search criteria, output options, and clicking the search button, a second page will appear listing the returned database entries. From this table, clicking on the filenames will submit a request to download the selected FITS file.

Object Name

The name of the astronomical object you want to search for. Examples of valid names include GAM-GEM, NGC1068, JUPITER, and HD45677. (Note no spaces are used in BEFS target names.)

When you search on the object name in the database, case will be ignored. The object name will *not* be wildcarded at the front and back (that's so if you innocently enter `IO`, you don't match things like `ORION`). You can wildcard the object name using `*`, however (for example, `*1987*`). You can also enter a comma-separated list; for example, `*JUP*,*SAT*` would match object names containing either `JUP` or `SAT`.

The SIMBAD and NED object name resolvers can only resolve fixed objects; they cannot compute the positions of moving objects (planets, comets, etc.). To find moving objects, try selecting the appropriate object class, entering an object name that could match what you're looking for, and selecting `Don't resolve` for the name resolver. NED is an extragalactic database, and generally won't resolve object names within the Milky Way galaxy.

Object Resolver

The name resolver will let you resolve an object name into its coordinates. This is useful particularly for searching for objects that may be known by different names. You can resolve an object name either before a search, or you can redraw the form with the the resolved coordinates in place. If you don't elect to to resolve the object name, the BEFS database will be searched on the object name given.

The SIMBAD and NED object name resolvers can only resolve fixed objects; they cannot compute the positions of moving objects (planets, comets, etc.). To find moving objects, try selecting the appropriate object class, entering an object name that could match what you're looking for, and selecting `Don't resolve` for the name resolver. NED is an extragalactic database, and generally won't resolve object names within the Milky Way galaxy.

To resolve an object name before a search, enter the object name in the **Object Name** field, select either `SIMBAD` or `NED` for the resolver, and hit the **Search** button. (NED is the Nasa Extragalactic Database at Caltech in Pasadena, California, and SIMBAD is the Set of Identifications, Measurements, and Bibliography for Astronomical Data at the Centre de Données astronomiques in Strasbourg, France.) The object name will be sent to SIMBAD, which will send back the coordinates. (If the object name is not recognized by the resolver, or there is some other problem with the SIMBAD service, then the search form will be redrawn with an error message at the top.) These coordinates will then be used to search the BEFS database, along with whatever other query qualifications you have given.

You can also hit the **Resolve** button instead of the **Search** button. In that case, the search form will be redrawn with the object's right ascension and declination entered as defaults in the **RA** and **Dec** fields. Resolving an object name will not change any other choices made in the form, except for the equinox, which will be reset to J2000 (since the SIMBAD resolver returns J2000 coordinates).

We recommend that you use object name resolution to find observations of specific objects in the database. This is the most reliable way to look up observations, because the observer could have given any object name at all (for example, `NGC1976` instead of `M42`). However, if you do know the object name that the observer used, you can select `Don't resolve`, in which case the object name will not be resolved into coordinates, but will be used as a search qualification in the database. (This will happen only when you press the **Search** button.)

Resolve

When you press this button and select `SIMBAD` for the resolver, the BEFS Search form will be redrawn with the coordinates for the given object entered into the RA and Dec fields. If you then press **Search**, the search will be conducted on that position. (The resolver will *not* be re-run for the search, unless you change either the object name or the resolver).

RA, Dec

The Right Ascension and Declination around which you want to search. These fields give the J2000 equatorial coordinates for the center of the image. A number of formats are accepted for the RA and Dec. Here are some examples:

```
Decimal Degrees
    185.63325 29.8959861111111

Hours, minutes and Seconds
    12 22 31.98      29 53 45.55
    12h22m31.98s     29d53m45.55s
    12:22:31.98     +29:53:45.55
    12h22'31.98"     29d53'45.55"
    12h 22m 31.98s   29d 53m 45.55s
    12h 22' 31.98"   29d 53' 45.55"
    12h 22' 31.98"  -29d 53' 45.55"
    12h22'31".98    -29d53'45".55
    12h22m31s.98    -29o53m45s.55
    12h 22' 31".98  -29d 53' 45".55

Hours/Degrees and Minutes (no seconds)
    12 22     29 53
    12h22m   +29d53m
    12h22m    29d53m
    12:22m    29:53m
    12h22'    29d53'
    12h 22m   29d 53m
    12h 22'   29d 53'
    12h 22'  -29d 53'

The RA may be given in decimal degrees
by indicating a D or d after the degrees:
    12d 22m   29d 53m
```

Spacing is not important, as long as the value is unambiguous, and that you delimit the hours/degrees, minutes, and (optional) seconds with letters, colons, spaces, or any character that's not a digit or a decimal point.

Note also that seconds of the form 31".98 or 31s.98 are accepted. This should make it easy to cut and paste values into these fields from electronic publications.

Radius

The radius of the search box around the RA and Dec, in floating-point arcminutes (e.g., `5.0`). You should be careful about giving too restrictive a search radius in an BEFS search.

Equinox

The equinox of the RA and Dec you have entered, either `B1950` or `J2000`. This only affects the input coordinates; there is a separate selector for the equinox of the output coordinates.

If you hit the **Resolve** button to get an object's coordinates and redraw the form, the equinox will be set to `J2000`, since that's the equinox of the coordinates returned by the object name resolvers.

Object Category

This is a broad category for the target. One or more values may be selected. Clicking "reset to defaults" or "clear form" (described below) will erase previous selections.

Observation Start Date

This is the GMT time, to the nearest second, of the start of the observation. (Note the BEFS1 observations were all obtained during December 2-10, 1990 and BEFS2 observations were obtained during March 2-18, 1995.)

When specifying this date, you need to include at least a date; a time is optional. The date can have any of the following formats (the month name can be spelled out or abbreviated to three letters; case is not significant):

```
Dec 15 1990
Dec 1990 15
15 Dec 1990
1990 Dec 15
1990 15 Dec
7/15/1990
7-15-1990
7.15.1990
```

If the day is omitted, the first day of the month is assumed. This means that a specification like "Dec 1990" will look for observations done on Dec 1 1990 00:00:00, *not* for observations done during Decy 1990. Note also that when entering a date with the month in numerical format, the American ordering is used; i.e., the first number is the month.

If a time is omitted, then any time for that day will match. Otherwise, you can specify a time in any of these formats:

```
14:30
14:30:20
14:30:20:999
14:30:20.9
4am
4 PM
04:30:20 AM
```

To search for observations before a given date, use <, and for observations after a given date, use >. For example,

```
> Dec 10 1990
< Dec 10 1990
```

You can use the .. operator to search on a range of dates:

```
Mar 2 1995 .. Mar 5 1995
```

This operator is inclusive on the first date and exclusive on the second.

Finally, you can search on a list of dates or date ranges. For example,

```
Mar 10 1995 .. Mar 11 1995,
Mar 15 1995 .. Mar 16 1995
```

will search for observations done within either one of these date ranges.

Exposure Time

The total exposure times in seconds. Note the times do not reflect pointing problems. In many cases, the target was not in the aperture.

Entry ID

The BEFS observation reference number uniquely defines each BEFS observation. The name is of the form **BEFSnnnn** where nnnn is a unique 4-digit number assigned sequentially in the order in which the observation was made, starting at 1000.

Output Columns

Your choice of what columns you want to see in the output. There are two radio buttons that let you select either the default set of columns, or choose your own set of columns.

The default set of columns for raw data sets is (in the order displayed):

```
Object Name
Entry_ID
RA (J2000)
Dec (J2000)
Observation Date
Exposure Time
Gratings
Object Category
Comments
More info
```

You can select your own output columns by pressing the `custom...` radio button and selecting the columns from the list below it. The output columns will be in the order in which they appear in this list.

Sort output by:

Choose how you want the output rows sorted. You can select up to three fields to sort on. the rows will be sorted in the order of the first sort field; if two rows have the same sort field, they will be sorted in order of the second sort field, and so on.

For each field, you can select that the rows be sorted in *reverse* order on that field by selecting the `reverse` checkbox. For example, you can sort the rows with the most recent observations first by selecting `Observation Date` for the first sort field and selecting the `reverse` checkbox next to it.

Maximum number of hits

Some queries will be capable of returning hundreds of rows or more. Such large search results tend to use up memory on both the client and server sides, and aren't usually useful. By default, we limit the number of rows displayed to 100 rows, but you can increase (or decrease) this limit as needed.

Output equinox

Just what you'd think: the equinox of the coordinates displayed in the output.

Show SQL Query

Select this checkbox if you want to see the SQL query that the BEFS Search engine constructs from your query qualifications. The query will be shown at the end of the search results.

SQL (Standard Query Language, pronounced either "ess cue ell" or "sequel") is a language used by most relational database systems for retrieving information from database tables. The BEFS Search Page takes your search specifications and converts them to an SQL query to run on our database. Viewing the generated query is often useful for debugging, and may also be useful for SQL-literate users who want to see what logic was used in the query. (In fact, this may be useful for most people, since SQL is pretty easy to understand.)

IMAPS Interstellar Medium Absorption Profile Spectrograph

IMAPS-1 Search Table

Below is the finding list for IMAPS-1 targets. Clicking on an entry in the table will display the appropriate section of the **raw** or **coadded** image tables from which the files can be downloaded (by clicking on the filename), or the FITS headers displayed (by clicking on HD number). Omitted from the list below are the background exposures although all background exposures are available in the raw image table. Note the Eta Uma exposures are divided into several groups based on changes in the exposure times (which are shown in parentheses).

The coadded images are usually comprised of 2 to 5 raw images which are coadded and corrected for various detector artifacts. The FITS files contain the coadded image as a primary array with wavelength information stored in a binary table. (see note on **Wavelength Accuracy**). The numbers listed below for the coadded files represent the range of exposure numbers used in each group of coadded images. As shown, coadded images do not exist for all of the observed targets. Although some raw images were not suitable for coadding, we expect more coadded files will become available in the near future.

Object Name	Raw Image Numbers	Coadded Image Numbers
gamma2 Vel	89-108 239-251 323-330	89-108
zeta Ori	109-124 195-214 378-408	109-124 195-214 378-402
zeta Pup	125-140 276-294 440-445	125-139 276-294 440-445
gamma Cas	141-148 220-238 331-355	141-146 220-238 331-355
epsilon Ori	150-173 296-322	150-172 296-322
alpha Eri	175-194 253-274 416-424 715-721	
beta Cru	356-375 410-415	
eta UMa (atmos. probe)	446-454(511) 455-514(255) 515-522(511) 525-532(511) 533-592(255) 594-601(511)	
kappa Ori	602-652 653-700	
beta Cen	702-713	705-713

Getting Started

The Interstellar Absorption Profile Spectrograph (IMAPS) is a very high-resolution (R ~ 240,000) spectrograph used to observe several bright, hot stars over the spectral region 950-1150Å. The instrument is especially well-suited for studies of interstellar absorption lines. IMAPS flew on on two shuttle missions, in September 1993 and November 1996, in conjuction with the ORFEUS mission.

Currently only data from the first mission, IMAPS-1, are available. This archive includes about 600 spectral images of 10 hot stars. The data are available in two forms, raw images and coadded images corrected for various detector artifacts. Six of the stars currently have coadded, corrected images available: gamma-2 Vel, zeta Ori, zeta Pup, gamma Cas, epsilon Ori, and beta Cen. The images are listed in the **search table**.

The data are available as spectral images in FITS format (see **Data Products**). The files may be read using software packages such IRAF or IDL (see **How to Read IMAPS Files**), although the software to extract the echelle spectra from these images is not yet available. Wavelength calibration information is furnished with the spectral image files.

Mission/category: IMAPS all Go

List all changes for IMAPS

More MAST mission data now on-line
2002 February 27
All IUE, UIT, BEFS and VLA-FIRST data are now on-line on a RAID array. The response time for data downloads for these missions should improve significantly. Data for missions HUT, WUPPE, TUES, and Copernicus were already on-line. HST and FUSE data remain on DADS and response times for data download for these two missions are not affected. EUVE data are held at HEASARC and this data is also not affected.

Name Resolver Option Available in Cross Correlation search
2002 January 15
The cross correlation search option available from the top MAST page now allows a choice of NED or SIMBAD for resolving user-specified target names. (The previous version only used SIMBAD.)

New MAST/ADS Data Links
2002 January 11
The ADS data links to data archived winthin MAST have been revised. Now a link to a single MAST page is shown which displays all the known MAST references for a single bibcode. (See 1995ApJ...449..488R as an example.)

New Plotting Option Offered in MAST Scrapbook
2001 October 18
A new option for coplotting multiple spectra and adjusting plot scales is now available in the MAST scrapbook.

Data Characteristics Plots Updated
2001 June 13
The MAST Data Characteristics plots have been updated to include the FUSE, TUES, BEFS, and SDSS missions.

Target Search Error
2001 June 12
An error was discovered in the target search available from the main MAST page. Searches would fail for object names containing special characters (such as a "+" symbol as in BD +28 4211). The error was fixed on the above date.

Implementation of Redesigned MAST Web Site
2001 June 4
The MAST redesigned web site is now online. The new dynamically-generated pages feature a common page layout, options for site-wide index searches, mission-specific target name searches, easier site navigation, and a printer-friendly page display option.

Cross Correlations with Sky2000 Catalog
2000 August 16
Cross correlations of MAST missions with the SKYMAP Sky2000 catalog (version 3) are now possible from the MAST Cross Correlation page.

New Copyright Notice
2000 May 12
STScI has adopted a new Copyright statement. Most, if not all, MAST web pages should now include a link to the new page.

Coadded IMAPS-1 Files now Accessible
1999 September 22
The available corrected and coadded IMAPS-1 files are now accessible from the IMAPS-1 search table. A description of the wavelength calibration procedure used is also available.

Revised IMAPS-1 FITS Files
1999 September 21
Comments were added to some IMAPS-1 files describing known problems with the images.

Revised IMAPS-1 FITS Files
1999 August 2
Dates listed in the IMAPS-1 raw image files are now given in GMT rather than days since launch.

IMAPS 1
1999 July 20
The raw data from the first IMAPS mission is now available through MAST.

IMAPS-1 Target List
1999 June 21
Target list page now includes links to display FITS headers of raw files.

More Documentation
1999 June 09
WEB pages were added on reading IMAPS files , and IMAPS file formats.

IMAPS-1 Search Table and Target List online
1999 April 30

IMAPS-1 Raw Data Available online
1999 April 12

Acknowledgments Page added
1999 February 5

New Documentation
1998 December 10
The paper "High Resolution Spectroscopy in the Far UV: Observations of the Interstellar Medium by IMAPS on Orfeus-SPAS" by Jenkins, Reale, Zucchino, Sofia (1996,Ap&SS,239,315J) was put online (with permission from Kluwer Academic Publishers).

FAQ Page
1998 August 5
An IMAPS "Frequently Asked Questions" (FAQ) page is now available. Users should send additional questions to archive@stsci.edu.

Frequently Asked Questions

Data Requests

- Where do I get IMAPS archival data?

Data Analysis

- How do I read a IMAPS FITS file?
- How do I extract data from IMAPS images?

Data Requests

- ***Where do I get IMAPS archival data?***
  At the end of the mission, Princeton provided the raw IMAPS-1 data to the National Space Science Data Center (**NSSDC**) in the form of IDL unformatted data sets. NSSDC staff converted these files to FITS format. The FITS headers were later modified by personnel from the **Laboratory for Astronomy and Solar Physics** (LASP) at Goddard Space Flight Center and the modified FITS files are now available from the **Multi-mission Archive at the Space Telescope Science Institute (MAST)**. Princeton also produced IDL data sets of coadded and corrected IMAPS-1 data. These data sets have been converted to FITS format by LASP personnel and will be available from MAST.

  IMAPS-2 data has not yet become available to the general community.

Data Analysis

- ***How do I read a IMAPS FITS file?***
  The raw data sets are basic FITS primary array files and should be readable by any FITS reader or FITS viewer. The corrected, coadded files contain a primary array, but also have wavelengths stored in a binary table, and the image filter in an image extension. See **Reading IMAPS Files** for more information.

- ***How do I extract data from IMAPS images?***
  An IDL routine called EXTRACT5 was written for extracting spectral data from the corrected IMAPS FITS files. More information on EXTRACT5 will be available soon.

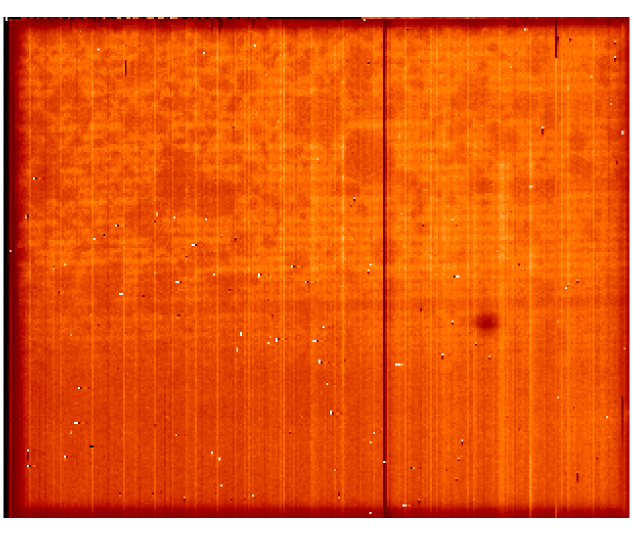
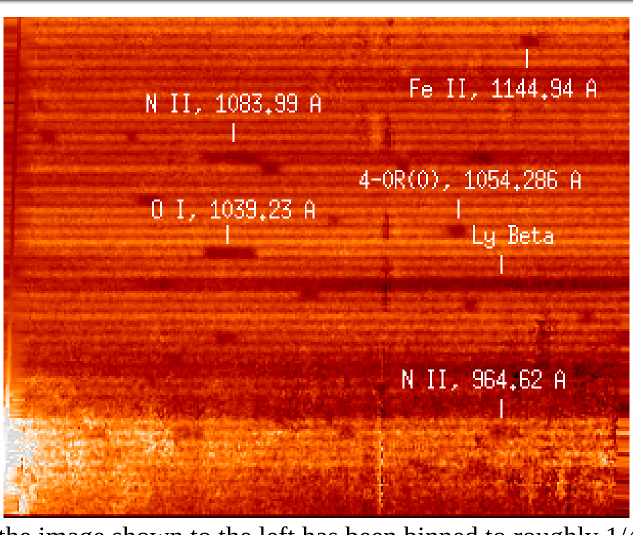
IMAPS Sample Images

The following are examples of IMAPS-1 spectral images:



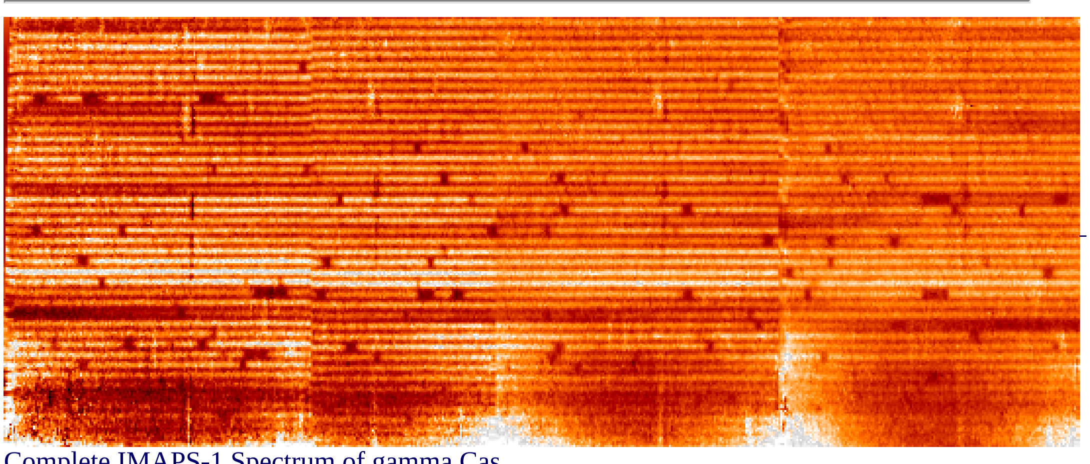
Raw image of gamma Cas - 16kb

This figure shows a raw image of gamma Cas (imaps1_0340.fits). Most of the prominent features are artifacts. The echelle spectral orders are barely discernable as light-colored horizontal lines. All raw images are 320x256 byte arrays, so each raw image FITS file is roughly 16 Kb.



Corrected & coadded image of gamma Cas - 2.6 MB

This figure represents one of the corrected and coadded images of gamma Cas (imaps1_340-342.fits). Most of the artifacts have been removed, and some of the more prominent features are labelled. The corrected IMAPS1 images are 640x512 floating point arrays (1.3 MB) although with the wavelength arrays and noise filter image, the complete corrected and coadded FITS file is roughly 2.6 MB. (Note the image shown to the left has been binned to roughly 1/4th of its original size. Clicking on the image will show the full size image.)



Complete IMAPS-1 Spectrum of gamma Cas

Four coadded, & corrected images of gamma Cas were spliced together to display the entire IMAPS-1 spectral coverage. The image shown was then rebinned to be about 1/8th the original size. (Clicking on the image will show a file binned to 1/4th original size.)

Acknowledgments

The MAST staff would like to thank the following groups and individuals for help in making the IMAPS data, documentation, and WEB site available to the public:

- **Ed Jenkins** (Princeton University Observatory), principal investigator for IMAPS 1 and IMAPS-2, for invaluable advice, documentation, and information in general on the IMAPS project,
- **George Sonneborn** (Goddard Space Flight Center, LASP) for assistance in creating the IMAPS archive, providing the data reduction software, amd explaining the IMAPS data format,
- the **Raytheon/STX ADF** staff including **Derck Massa,** and **Jeff Silvis**, for creating the original IMAPS-1 raw data FITS files,
- **Kluwer Academic Publishers**, publishers of "Astrophysics and Space Sciences" and "Experimental Astronomy", for permission to reprint the article "High Resolution Spectroscopy in the Far UV: Observations of the Interstellar Medium by IMAPS on ORFEUS-SPAS by Jenkins, Reale, Zucchino, and Sofia (1996 Ap&SS,239,315J). Special thanks go to **Berendina Schermers-van Straalen**, Rights and Permissions Manager for Kluwer Academic Publishers.

IMAPS-1 Raw Image Table

Below is the finding list for IMAPS-1 targets shown in the order in which the observations were obtained.
Clicking on the file name entry will download the selected raw data FITS file.
Clicking on the HD number will display the FITS file header.

IMAPS-1 Coadded, Corrected File Table

Below is the list of IMAPS-1 coadded, corrected files.
Clicking on the file name entry will download the selected FITS file.
Clicking on the HD number will display the FITS file header.

File Name	Object	HD	Echelle	Mid Start Time

IMAPS-1 Wavelength Calibration

The IMAPS-1 wavelengths were generated using an IDL routine (wave1.pro) which requires as input, the x and y pixel location, and the order number and wavelength, of one spectral feature identified in the IMAPS image. Based on this one fiducial wavelength, the program generates a wavelength array for each order. The starting wavelength and wavelength increment are then stored in the binary table extension contained in the coadded image FITS file.

The table below shows the wavelength (in Å), order number, echelle position (1-4), x & y position (in pixels), and the line identification for the fiducial spectral feature used in each of the coadded, corrected IMAPS-1 images. Since these line identifications are the basis for the IMAPS-1 wavelength calibrations, any errors in these values would affect the wavelength calibration for that particular image.

Note that no other wavelength corrections have been applied to the IMAPS-1 files, and the source of the absorption line used determines the wavelength reference frame. For example, since most of the files use interstellar lines, the wavelength assignments would correspond to an interstellar reference frame. Note telluric lines were used for a few files.

File	Wavelength (A)	Order	Pos	X,Y Values (pixels)	Element

IMAPS Search Help

There are two types of IMAPS-1 data: raw images, and corrected, coadded images. Only the coadded files have assigned wavelengths. To download an IMAPS file, click on any of the listed image numbers for the desired target. This will display a list of links to individual files that can then be downloaded.

Object Name
: The common name of the astronomical object. (All the observed objects are listed in the table.)

Image Numbers
: The IMAPS image number (or exposure sequence number) listed in the table and contained in the file names, desribes the order in which the IMAPS observations were obtained. Exposure numbers ran from 0000 to 0721, however the first 79 were test exposures and not archived. The IMAPS-2 sequnce numbers will begin where IMAPS-1 left off.

With IMAPS-1, a series of observations were usually taken of a particular star. The series would usually include 2-4 exposures from each of the 4 echelle positions, plus a background exposure which involved leaving the aperture open and the telescope pointed toward the object but turning off the high voltage. Exposures within these series taken at the same echelle position were possible candidates for coadding.

Mid Start Time
: The average start date and time, in GMT, for the coadded images, based on the observation start dates calculated for the raw image files. Since the coadded exposures were usually taken consecutively, the observing times generally differ by only a few minutes.

Observation Start Date
: The start date and time, in GMT, for the particular IMAPS image. These times were determined by subtracting the exposure times from the observation end times recorded in the IMAPS-1 exposure log.

Echelle Position
: This entry describes either the position of the echelle grating (a number from 1 to 4) or whether a background exposure was obtained (a value of "B"). Each grating position covers 1/4 of each echelle order, so a series of four exposure is needed to cover the entire echelle spectrum.

HD Number
: The Henry Draper catalog number.

Filename
: The assigned file name. The raw data sets file names use the naming convention imaps1_0nnn.fits where nnn is the 3-digit exposure sequence number assigned by Princeton Observatory describing the order in which targets were observed (i.e., the first archived observation is imaps1_0079.fits and the last target is imaps1_0721.fits. Clicking on the raw file name in the IMAPS-1 finding list table will download the selected raw data FITS file.

The coadded scan file names are defined as imaps1_nnn-mmm.fits where nnn is the first coadded observation number and mmm is the last.

IMAPS-1 Search Table

Below is the finding list for IMAPS-1 targets. Clicking on an entry in the table will display the appropriate section of the **raw** or **coadded** image tables from which the files can be downloaded (by clicking on the filename), or the FITS headers displayed (by clicking on HD number). Omitted from the list below are the background exposures although all background exposures are available in the raw image table. Note the Eta Uma exposures are divided into several groups based on changes in the exposure times (which are shown in parentheses).

The coadded images are usually comprised of 2 to 5 raw images which are coadded and corrected for various detector artifacts. The FITS files contain the coadded image as a primary array with wavelength information stored in a binary table. (see note on **Wavelength Accuracy**). The numbers listed below for the coadded files represent the range of exposure numbers used in each group of coadded images. As shown, coadded images do not exist for all of the observed targets. Although some raw images were not suitable for coadding, we expect more coadded files will become available in the near future.

Object Name	Raw Image Numbers	Coadded Image Numbers
gamma2 Vel	**89-108** **239-251** **323-330**	**89-108**

TUES Search Help

The MAST search pages basically contain three parts. The top of the page lists the input search fields. Entering values (as described below) for one or more of these fields will define the selection criteria for the database search. The middle of the form contains buttons to initiate various actions including:

1. perform the search using the specified search criteria and output format,
2. clear the search form and reset values to the original defaults,
3. reset entries to the set of (default) values used the previous time the search page was drawn, and
4. display this help page.

The bottom portion of the page deals with formatting the table of found entries that appears after the search is completed. The format options include specifying which columns appear in the output list, the order of the entries, the maximum number of returned entries, the epoch of the output coordinates, and the option to display the actual SQL command used to retrieve the database entries. First time users may want to run the search using the default output options.

After selecting search criteria, output options, and clicking the search button, a second page will appear listing the returned database entries. From this table, clicking on the filenames will submit a request to download the selected FITS file.

Object Name

The name of the astronomical object you want to search for. Examples of valid names include GAM-GEM, NGC1068, JUPITER, and HD45677.

When you search on the object name in the database, case will be ignored. The object name will *not* be wildcarded at the front and back (that's so if you innocently enter `IO`, you don't match things like `ORION`). You can wildcard the object name using `*`, however (for example, `*1987*`). You can also enter a comma-separated list; for example, `*JUP*,*SAT*` would match object names containing either `JUP` or `SAT`.

The SIMBAD and NED object name resolvers can only resolve fixed objects; they cannot compute the positions of moving objects (planets, comets, etc.). To find moving objects, try selecting the appropriate object class, entering an object name that could match what you're looking for, and selecting `Don't resolve` for the name resolver. NED is an extragalactic database, and generally won't resolve object names within the Milky Way galaxy.

Object Resolver

The name resolver will let you resolve an object name into its coordinates. This is useful particularly for searching for objects that may be known by different names. You can resolve an object name either before a search, or you can redraw the form with the the resolved coordinates in place. If you don't elect to to resolve the object name, the TUES database will be searched on the object name given.

The SIMBAD and NED object name resolvers can only resolve fixed objects; they cannot compute the positions of moving objects (planets, comets, etc.). To find moving objects, try selecting the appropriate object class, entering an object name that could match what you're looking for, and selecting `Don't resolve` for the name resolver. NED is an extragalactic database, and generally won't resolve object names within the Milky Way galaxy.

To resolve an object name before a search, enter the object name in the **Object Name** field, select either `SIMBAD` or `NED` for the resolver, and hit the **Search** button. (NED is the Nasa Extragalactic Database at Caltech in Pasadena, California, and SIMBAD is the Set of Identifications, Measurements, and Bibliography for Astronomical Data at the Centre de Données astronomiques in Strasbourg, France.) The object name will be sent to SIMBAD, which will send back the coordinates. (If the object name is not recognized by the resolver, or there is some other problem with the SIMBAD service, then the search form will be redrawn with an error message at the top.) These coordinates will then be used to search the TUES database, along with whatever other query qualifications you have given.

You can also hit the **Resolve** button instead of the **Search** button. In that case, the search form will be redrawn with the object's right ascension and declination entered as defaults in the **RA** and **Dec** fields. Resolving an object name will not change any other choices made in the form, except for the equinox, which will be reset to J2000 (since the SIMBAD resolver returns J2000 coordinates).

We recommend that you use object name resolution to find observations of specific objects in the database. This is the most reliable way to look up observations, because the observer could have given any object name at all (for example, `NGC1976` instead of `M42`). However, if you do know the object name that the observer used, you can select `Don't resolve`, in which case the object name will not be resolved into coordinates, but will be used as a search qualification in the database. (This will happen only when you press the **Search** button.)

Resolve

When you press this button and select `SIMBAD` for the resolver, the TUES Search form will be redrawn with the coordinates for the given object entered into the RA and Dec fields. If you then press **Search**, the search will be conducted on that position. (The resolver will *not* be re-run for the search, unless you change either the object name or the resolver).

RA, Dec

The Right Ascension and Declination around which you want to search. These fields give the J2000 equatorial coordinates for the center of the image. A number of formats are accepted for the RA and Dec. Here are some examples:

```
Decimal Degrees
    185.63325 29.8959861111111

Hours, minutes and Seconds
    12 22 31.98       29 53 45.55
    12h22m31.98s      29d53m45.55s
    12:22:31.98      +29:53:45.55
    12h22'31.98"      29d53'45.55"
    12h 22m 31.98s    29d 53m 45.55s
    12h 22' 31.98"    29d 53' 45.55"
    12h 22' 31.98"   -29d 53' 45.55"
    12h22'31".98     -29d53'45".55
    12h22m31s.98     -29o53m45s.55
    12h 22' 31".98   -29d 53' 45".55

Hours/Degrees and Minutes (no seconds)
    12 22      29 53
    12h22m    +29d53m
    12h22m     29d53m
    12:22m     29:53m
    12h22'     29d53'
    12h 22m    29d 53m
    12h 22'    29d 53'
    12h 22'   -29d 53'

The RA may be given in decimal degrees
by indicating a D or d after the degrees:
    12d 22m    29d 53m
```

Spacing is not important, as long as the value is unambiguous, and that you delimit the hours/degrees, minutes, and (optional) seconds with letters, colons, spaces, or any character that's not a digit or a decimal point.

Note also that seconds of the form 31".98 or 31s.98 are accepted. This should make it easy to cut and paste values into these fields from electronic publications.

Radius

The radius of the search box around the RA and Dec, in floating-point arcminutes (e.g., `5.0`). You should be careful about giving too restrictive a search radius in an TUES search.

Equinox

The equinox of the RA and Dec you have entered, either `B1950` or `J2000`. This only affects the input coordinates; there is a separate selector for the equinox of the output coordinates.

If you hit the **Resolve** button to get an object's coordinates and redraw the form, the equinox will be set to `J2000`, since that's the equinox of the coordinates returned by the object name resolvers.

Object Category

This is a broad category for the target. One or more values may be selected. Clicking "reset to defaults" or "clear form" (described below) will erase previous selections.

Observation Start Date

This is the GMT time, to the nearest second, of the start of the observation. (Note the TUES1 observations were all obtained during December 2-10, 1990 and TUES2 observations were obtained during March 2-18, 1995.)

When specifying this date, you need to include at least a date; a time is optional. The date can have any of the following formats (the month name can be spelled out or abbreviated to three letters; case is not significant):

```
Dec 15 1990
Dec 1990 15
15 Dec 1990
1990 Dec 15
1990 15 Dec
7/15/1990
7-15-1990
7.15.1990
```

If the day is omitted, the first day of the month is assumed. This means that a specification like "Dec 1990" will look for observations done on Dec 1 1990 00:00:00, *not* for observations done during Decy 1990. Note also that when entering a date with the month in numerical format, the American ordering is used; i.e., the first number is the month.

If a time is omitted, then any time for that day will match. Otherwise, you can specify a time in any of these formats:

```
14:30
14:30:20
14:30:20:999
14:30:20.9
4am
4 PM
04:30:20 AM
```

To search for observations before a given date, use <, and for observations after a given date, use >. For example,

```
> Dec 10 1990
< Dec 10 1990
```

You can use the .. operator to search on a range of dates:

```
Mar 2 1995 .. Mar 5 1995
```

This operator is inclusive on the first date and exclusive on the second.

Finally, you can search on a list of dates or date ranges. For example,

```
Mar 10 1995 .. Mar 11 1995,
Mar 15 1995 .. Mar 16 1995
```

will search for observations done within either one of these date ranges.

Exposure Time

The total exposure times in seconds. Note the times do not reflect pointing problems.

Entry ID

The TUES observation reference number uniquely defines each TUES observation. The name is of the form **TUESid_obs** where id = a special ORFEUS target identification number (4 digits), and obs = the observation number for this target, sometimes followed by an underline character and the number of the pointings during this observation. Several pointings during a single observation were carried out sometimes to improve the alignment of the telescope ("grid search"). This resulted partially in very short integrations. "_PH" denotes an integration from single photon events recorded onboard but integrated after the mission.

Output Columns

Your choice of what columns you want to see in the output. There are two radio buttons that let you select either the default set of columns, or choose your own set of columns.

The default set of columns for raw data sets is (in the order displayed):

```
Object Name
Entry_ID
RA (J2000)
Dec (J2000)
Observation Date
Exposure Time
Object Category
Comments
More info
```

You can select your own output columns by pressing the `custom...` radio button and selecting the columns from the list below it. The output columns will be in the order in which they appear in this list.

Sort output by:

Choose how you want the output rows sorted. You can select up to three fields to sort on. the rows will be sorted in the order of the first sort field; if two rows have the same sort field, they will be sorted in order of the second sort field, and so on.

For each field, you can select that the rows be sorted in *reverse* order on that field by selecting the `reverse` checkbox. For example, you can sort the rows with the most recent observations first by selecting `Observation Date` for the first sort field and selecting the `reverse` checkbox next to it.

Maximum number of hits

Some queries will be capable of returning hundreds of rows or more. Such large search results tend to use up memory on both the client and server sides, and aren't usually useful. By default, we limit the number of rows displayed to 100 rows, but you can increase (or decrease) this limit as needed.

Output equinox

Just what you'd think: the equinox of the coordinates displayed in the output.

Show SQL Query

Select this checkbox if you want to see the SQL query that the TUES Search engine constructs from your query qualifications. The query will be shown at the end of the search results.

SQL (Standard Query Language, pronounced either "ess cue ell" or "sequel") is a language used by most relational database systems for retrieving information from database tables. The TUES Search Page takes your search specifications and converts them to an SQL query to run on our database. Viewing the generated query is often useful for debugging, and may also be useful for SQL-literate users who want to see what logic was used in the query. (In fact, this may be useful for most people, since SQL is pretty easy to understand.)

The STScI Digitized Sky Survey

DSS Mini-Window * Form with Tables

NOTE: This page should *not* be used to obtain target coordinates for HST Phase 2 proposals. Instead, use the Phase 2 form to make sure you're extracting from the right plates.

RETRIEVE IMAGE | Clear the form

Extractions will be from the Quick V survey for northern declinations, and from the 1st generation scans for southern declinations. This will ensure that your submitted positions are in the HST Guide Stars frame.

All images will be in FITS format. Your browser should attempt to save the file to disk instead of trying to display it.

Scientific citations of this data must include information given in the acknowledgments.

Search Help

How to use the CGI script directly

Get an Object's Coordinates

To get an image from the Digitized Sky Survey, you will need the right ascension and declination of the area you're interested in. However, if all you know is the name of an object and don't have its coordinates handy, you can use this section to get the coordinates for you.

The coordinates will come from either the SIMBAD database in Strasbourg, France, or the NASA Extragalactic Database (NED) in Pasadena, California. SIMBAD contains comprehensive lists of all kinds of objects from all the major astronomical catalogs, while NED concentrates on objects outside our galaxy. (Neither can return coordinates for solar system objects.)

To get an object's coordinates, enter its name, select a resolver, and hit the "GET COORDINATES" button. The form will redraw itself with the object's coordinates filled in.

Getting an object's coordinates may take a moment if the networks are busy, so please be patient.

Retrieve an Image

This is the section where you specify what kind of image you want.

NOTE: *Any entries you make in this section of the form will be erased if you use the "GET COORDINATES" feature!*

Generation

Here, you select which generation of the Sky Survey you want. The First Generaton comprises the older surveys, scanned at about 1.7 arcsec per pixel. The Second Generation is from a newer ongoing survey, scanned at about 1 arcsec per pixel. Consequently, the images from the Second Generation scans will be larger than from the First: a 15'x15' Second Generation FITS image will be about 1.5 megabytes (a First Generation scan of the same size is about 570 kilobytes), so you may want to select smaller scan sizes when getting images from the Second Generation survey.

Not all of the Second Generation DSS scans have been loaded; here is a list of Second Generation scans currently available.

Coordinates (RA, Dec, and Equinox)

Enter the Right Ascension and Declination on which you would like the scan to be centered (you won't need to enter it if you use the Target Name Resolver), and select either J2000 or B1950 for the equinox of the coordinates.

A number of formats are accepted for the RA and Dec. Here are some examples:

```

    12h 22' 31".98   -29d 53' 45".55

Hours/Degrees and Minutes (no seconds)
    12 22      29 53
    12h22m    +29d53m
    12h22m     29d53m
    12:22m     29:53m
    12h22'     29d53'
    12h 22m    29d 53m
    12h 22'    29d 53'
    12h 22'   -29d 53'

The RA may be given in decimal degrees by indicating
a D or d after the degrees:
    12d 22m    29d 53m
```

Spacing is not important, as long as the value is unambiguous, and that you can delimit the hours/degrees, minutes, and (optional) seconds with letters, colons, spaces, or any character that's not a digit or a decimal point.

Note also that seconds of the form 31".98 or 31s.98 are accepted. This should make it easy to cut and paste values into these fields from electronic publications.

Image size

Specify a field size for the for the returned image by entering a hieght and width in arcminutes. The default size is 15' x 15', which yields a FITS file of about 530 kbytes, or a GIF image of usually around 160 kbytes. (The maximum size, 60 arcminutes, produces an 8-megabyte FITS file.)

Format

Select either FITS or GIF.

FITS files will be delivered with a MIME type of `image/fits`;
GIF files will be delivered with a MIME type of `image/gif`.

If you are using a graphical Web browser (Mosaic, Netscape, etc), you may be able to configure your browser to display the FITS images returned by this form instead of saving them to disk. Here is an example, showing how to configure a Unix-based browser for displaying the images in SAOimage.

Compression

Select a compression method. This will only be applied if you select FITS as the image format.

- NONE - the FITS file will be delivered uncompressed.
- Unix - The FITS file will be compressed with the Unix `compress` command.
- gzip - The FITS file will be compressed with the `gzip` command.

Field of View Overlay

If you would like the HST field of view (FOV) overlaid onto a GIF image from the First Generation scans, you can select that here. The FOV shows the placement within the field of the apertures of HST's science instruments for a given spacecraft roll angle. Select:

- NONE - No FOV will be drawn on the image.
- LAUNCH - After launch of HST in Apr 1990 and before the First Servicing Mission in Dec 1993 (the pre-COSTAR era).
- SM93 - After the First Servicing Mission, Dec 1993, and before the Second Servicing Mission, Feb 1997 (post-COSTAR, but before STIS and NICMOS).
- SM97 - After the Second Servicing Mission, Feb 1997, showing STIS and NICMOS apertures.

and enter the desired Roll Angle. (This is the V3 roll angle, 180 degrees from the U3 roll angle.)

HST's total field of view is about 30 arcminutes across, so to get the entire FOV in the image, you will need to select a height and width of about 30' x 30'. (A 25'x25' field will also show the FOV will a little clipping at the edges.)

Remember, FOVs may only be drawn on GIF-formatted images from the First Generation Survey. If you select FITS, or if you select another survey, then your FOV selection will be ignored.

DSS Digitized Sky Survey

Produced under Contract No. NAS5-26555 with the National Aeronautics and Space Administration.

See also acknowledgements

DSS Digitized Sky Survey

Investigators using these scans are requested to include these acknowledgments in any publications as appropriate.

The Digitized Sky Surveys were produced at the Space Telescope Science Institute under U.S. Government grant NAG W-2166. The images of these surveys are based on photographic data obtained using the Oschin Schmidt Telescope on Palomar Mountain and the UK Schmidt Telescope. The plates were processed into the present compressed digital form with the permission of these institutions.

The National Geographic Society - Palomar Observatory Sky Atlas (POSS-I) was made by the California Institute of Technology with grants from the National Geographic Society.

The Second Palomar Observatory Sky Survey (POSS-II) was made by the California Institute of Technology with funds from the National Science Foundation, the National Geographic Society, the Sloan Foundation, the Samuel Oschin Foundation, and the Eastman Kodak Corporation.

The Oschin Schmidt Telescope is operated by the California Institute of Technology and Palomar Observatory.

The UK Schmidt Telescope was operated by the Royal Observatory Edinburgh, with funding from the UK Science and Engineering Research Council (later the UK Particle Physics and Astronomy Research Council), until 1988 June, and thereafter by the Anglo-Australian Observatory. The blue plates of the southern Sky Atlas and its Equatorial Extension (together known as the SERC-J), as well as the Equatorial Red (ER), and the Second Epoch [red] Survey (SES) were all taken with the UK Schmidt.

Supplemental funding for sky-survey work at the ST ScI is provided by the European Southern Observatory.

DSS Digitized Sky Survey

There are several Web sites around the world offering the Digitized Sky Survey. If your site offers a public access to the Digitized Sky Survey, let us know and we'll add it here.

UNITED STATES

STScI Digitized Sky Survey
Space Telescope Science Institute, Baltimore, Maryland
http://archive.stsci.edu/dss/

That's us. Our site features access to both the First and Second Generation sky surveys, and can overlay HST's field of view onto GIF images.

SkyView
Goddard Space Flight Center, Greenbelt, Maryland
http://skyview.gsfc.nasa.gov/

A muli-wavelength virtual observatory. Features the 1st Generation DSS along with high energy, ultraviolet, infrared, and radio surveys. Can plot grids on images. There are several forms to choose from, including a new Java interface.

CANADA

Canadian Astronomy Data Centre
Dominion Astrophysical Observatory, Victoria, British Columbia
http://cadcwww.dao.nrc.ca/dss/

Features access to both First and Generation surveys and a batch mode.

EUROPE

Aladin
Centre de donnees astronomiques de Strasbourg (CDS)
http://aladin.u-strasbg.fr/aladin.gml

Aladin is an interactive software sky atlas allowing the user to visualize digitized images of any part of the sky, to superimpose entries from astronomical catalogs or personal user data files, and to interactively access related data and information from the SIMBAD, NED, VizieR, or other archives for all known objects in the field.

ESO Online Digitized Sky Survey
European Southern Observatory, Garching, Germany
http://archive.eso.org/dss/dss/

SkyEye
Instituto di Radioastronomia, Bologna, Italy
http://terra.bo.cnr.it/skyeye/gb/

This site offers the files in FITS, GIF, GEIS, or JPEG, and features a batch queue and email interface. It also has a feature to make the FITS files compatible with AIPS. (Access from the US may be slow.)

SkyEye is part of the Astronomical Virtual Observatory.

LEDAS Digitized Sky Survey Image Browser
Leicester Database and Archive Service, University of Leicester, UK
http://ledas-www.star.le.ac.uk/DSSimage/

An experimental service offering a simple and quick interface.

ASIA

Digitized Sky Survey Online
National Astronomical Observatory of Japan, Tokyo, Japan
http://dss.mtk.nao.ac.jp/

NAOJ offers access to both the 1st and 2nd Generation Digitized Sky Surveys, a batch email interface, and access to the IRAS Sky Survey Atlas (ISSA) and the Green Bank Sky Map (GBSM). (Access from outside Asia may be slow.)

SDSS Version 0.02

SDSS Catalog Search Help

Use the SDSS Catalog Search form to search the SDSS Catalog by object name, position, object type, or simple selections by magnitude for each of the photometric bands.

Object Name

The name of the astronomical object you want to search for.

Object Resolver

The name resolver you want to use, if you want to resolve an object into its coordinates. You can resolve an object name either before a search, or you can redraw the form with the resolved coordinates in place. You can also elect not to resolve the object name when doing the search, but to search the IUE database on the object name given.

To resolve an object name before a search, enter the object name in the **Object Name** field, select either `NED` or `SIMBAD` for the resolver, and hit the **Search** button. (NED is the Nasa Extragalactic Database at Caltech in Pasadena, California, and SIMBAD is the Set of Identifications, Measurements, and Bibliography for Astronomical Data at the Centre de Données astronomiques in Strasbourg, France.) The object name will be sent to the chosen resolver, which will send back the coordinates. (If the object name is not recognized by the resolver, or there is some other problem with the SIMBAD or NED services, then the search form will be redrawn with an error message at the top.) These coordinates will then be used to search the SDSS Catalog, along with whatever other query qualifications you have given.

You can also hit the **Get coordinates** button instead of the **Search** button. In that case, the search form will be redrawn with the object's right ascension and declination entered as defaults in the **RA** and **Dec** fields. Resolving an object name will not change any other choices made in the form, except for the equinox, which will be reset to J2000 (since both the SIMBAD and NED resolvers return J2000 coordinates).

We recommend that you use object name resolution to find observations of specific objects in the database. This is the most reliable way to look up observations, because the observer could have given any object name at all (for example, `NGC1976` instead of `M42`, or `PARALLEL-FIELD`). However, if you do know the object name that the observer used, you can select `Don't resolve`, in which case the object name will not be resolved into coordinates, but will be used as a search qualification in the database. (This will happen only when you press the **Search** button.)

When you search on the object name in the database, case will be ignored. The object name will *not* be wildcarded at the front and back (that's so if you innocently enter `IO`, you don't match things like `ORION`). You can wildcard the object name using `*`, however (for example, `*IO*`). You can also enter a comma-separated list; for example, `*JUP*,*SAT*` would match object names containing either `JUP` or `SAT`.

The SIMBAD and NED object name resolvers can only resolve fixed objects; they cannot compute the positions of moving objects (planets, comets, etc.). To find moving objects, try selecting the appropriate object class, entering an object name that could match what you're looking for, and selecting `Don't resolve` for the name resolver. NED is an extragalactic database, and generally won't resolve object names within the Milky Way galaxy.

Resolve

When you select either `NED` of `SIMBAD` for the resolver and then press the "Get coordinates" button, the IUE Search form will be redrawn with the coordinates for the given object entered into the RA and Dec fields. If you then press **Search**, the search will be conducted on that position. (The resolver will *not* be re-run for the search, unless you change either the object name or the resolver).

RA, Dec

The Right Ascension and Declination around which you want to search. A number of formats are accepted for the RA and Dec. Here are some examples:

```
Decimal Degrees
    185.63325 29.8959861111111

Hours, minutes and Seconds
    12 22 31.98      29 53 45.55
    12h22m31.98s     29d53m45.55s
    12:22:31.98     +29:53:45.55
    12h22'31.98"     29d53'45.55"
    12h 22m 31.98s   29d 53m 45.55s
    12h 22' 31.98"   29d 53' 45.55"
    12h 22' 31.98"  -29d 53' 45.55"
    12h22'31".98    -29d53'45".55
    12h22m31s.98    -29o53m45s.55
    12h 22' 31".98  -29d 53' 45".55

Hours/Degrees and Minutes (no seconds)
    12 22      29 53
    12h22m   +29d53m
    12h22m    29d53m
    12:22m    29:53m
    12h22'    29d53'
    12h 22m   29d 53m
    12h 22'   29d 53'
    12h 22'  -29d 53'

The RA may be given in decimal degrees by indicating
a D or d after the degrees:
    12d 22m   29d 53m
```

Spacing is not important, as long as the value is unambiguous, and that you can delimit the hours/degrees, minutes, and (optional) seconds with letters, colons, spaces, or any character that's not a digit or a decimal point.

Note also that seconds of the form 31".98 or 31s.98 are accepted. This should make it easy to cut and paste values into these fields from electronic publications.

Radius

The radius of the search box around the RA and Dec, in floating-point arcminutes (e.g., `5.0`). You should be careful about giving too restrictive a search radius in an IUE search: the coordinates are coordinates of the *object* as given by the Guest Observer, and since acquisitions were made in real time, these coordinates may not reflect the precise pointing of IUE at the time of the observation.

Equinox

The equinox of the RA and Dec you have entered, either `B1950` or `J2000`. This only affects the input coordinates; there is a separate selector for the equinox of the output coordinates.

If you hit the **Resolve** button to get an object's coordinates and redraw the form, the equinox will be set to `J2000`, since that's the equinox of the coordinates returned by the object name resolvers.

Object Type

Searches may be qualified for the following object types:

- GALAXY
- STAR
- SKY
- COSMIC RAY
- KNOWNOBJECT
- TRAIL
- GHOST
- UNKNOWN
- NOTATYPE

More information on the objects classes can be found in the Photo Object documentation.

Magnitudes

Magnitude ranges may be specified in each of the different filters to qualify a search by position.
ranges such as:
21 .. 22 can be specified

A quick summary of the filters can be found in the User's Guide .

Colors

Differences in colors may be specified by range in bands:.
such as -0.5 .. 0.5, for the colors (to qulaify a positional search):

- u-g
- g-r
- r-i
- i-z

As a starting point, more information on color ranges can be found in the photometric accuracy pages of the User's Guide.

SDSS Relevant Software

---

1. SDSS Science Archive Query Tool (sdssQT)

sdssQT v2.3.2 is available.

The SDSS Query Tool (sdssQT) is a Graphical User Interface (GUI) that provides the functionality necessary for SDSS users to prepare and submit simple or complex queries to the Science Archive. The current interface is a Tcl/Tk client application that allows you to connect to the SDSS Catalog Archive Server and run queries on the Catalog Archive. You will need Tcl/Tk version 8.0 or later installed on your machine, and have a "wish" executable in your path that runs a wish8.0 or later. Many platforms have this already.

Before you install, we strongly recommend that you join the SDSS Users' Group. This list will allow us to alert you to necessary upgrades in both software and documentation, as well as scheduled database downtimes. This list will only be used for such time-critical notification of users. The other group, the SDSS Users' Forum, is a bulletin board for SDSS scientists, and is open to all fellow scientists interested in the SDSS.

Download and install the sdssQT version 2.3.2, and don't forget the tool that converts bin to FITS binary tables (including instructions for compilation and installation.) For the EDR, we have made available the latest fully functional version of the Query Tool, which is called ``sxQT" or "sdssQT".
The official SDSS QT guide is available below. You need JavaScript enabled to read the documentation.

SDSS QT Early Data Release User's Guide : last update Jan 28, 2002

You may need a complete description of the SDSS database structure and classes: sxQT documentation for classes and database descriptions

You can check if Tcl/Tk is installed with a "which wish" command. Tcl/Tk can be downloaded from the following site(s):
Tcl/Tk 8.0
Tcl/Tk 8.3

A Tcl/Tk installation caveat: the default tcl/tk installation names the "wish" executable with a version number, e.g. "wish8.0". The SDSS Query Tool script looks for an executable with just the name "wish", so the user needs to add a logical link "ln -s wish8.0 wish" in the bin directory where the executable is installed.

Start-Up hints from a novice for a novice:

1. The executable brings up a blank square. To start the action, use the Connect menu option.
2. The server requires a username password combination. Use username *guest* and password *archive*.
3. Select the FermiEDR as the server.
4. Try a File>Load Examples>Simple Tutorials for a sample of how the tool works. These tutorials can be modified with guidance from the SDSS QT and database documentation.
5. Output can be directed to a local file, remote file or remote socket, with some format options.

---

2. readAtlasImages

SDSS standalone programs to read fpBin, fpAtlas, and fpField files

- README file; ASCII
- file. Shift-click to download.

SDSS Spectral Pages

This page provides an introduction to the MAST SDSS Spectral Data Products tool. The Catalog interface will also use this interface for requesting data. More description will appear here after the tool is fully complete. A cookbook thread is available for use with SDSS Query Tool. Users of the MAST Catalog Interface will not need a cookbook thread.

There is also a cgi tool which allows users to download the SDSS 1-D spectra. The link below is to retrieve spectra with line identifications and these are available in either **FITS** or **gif** format. Additional spectral retrieval options which are better integrated with the catalog searches will become available in the future. 1-D Spectra
may be requested by **Full Fiberid** , **Compact ID** and **RA and DEC**

A suite of cgi tools for the SDSS is available for multiple data product retrieval.

Images

From these pages you will have access to the image products from the SDSS: MAST SDSS Image Data Product Retrieval .

An alternative source for atlas images and the recontructed, and the corrected frames is the cgi tool page hosted by Fermilab.

Most users will have to conduct a catalog search using either the MAST Catalog Search or the SDSS Query Tool to collect the parameters needed to make a request for the images. The MAST Catalog Search will allow users to put the objects of interest into a shopping basket, then request the products for those objects. The SDSS Query Tool results can be copied into the MAST SDSS Image Data interface. A cookbook thread describes this process.

SDSS Catalog Access

Access to the Catalog Archive Server can be made via the MAST interface, the SkyServer interface, or the SDSS Query Tool. The catalog contains measured quantities (variously called parameters or attributes) for detected objects from imaging and spectroscpic data.

Simple Interface: A basic MAST SDSS Catalog Form (*which actually interfaces with the sky Server*) allows searches by source sky position in equatorial coordinates RA and Dec or by position obtained from a name resolver (NED or SIMBAD). Queries may be additionally constrained by limiting the object types, magnitudes and colors. All queries must have a position constraint, however, because the server and the typical browser could overload on a more open-ended query.

A request for data products can be made directly from this interface, using the convention of a shopping cart. Viewing query results in html format also allows the user to mark the objects for which products are desired. The user can "Add marked records to shopping cart". When the shopping cart list is complete the user then can "Retrieve data products for shopping cart". This request brings up the MAST SDSS products form, properly populated with the object identification records (run/rerun/camcol/fieldID/ObjectID). The user can then customize the request, specifying product types, bands (for relevant imaging data) and file format (tar.gz, .tar, .zip).

Advanced Interface: Download the SDSS Query Tool Program and documentation sdssQT. This interface allows for more general queries of all parameters in the catalogs and data-mining.

The SDSS Query Tool will also allow users to copy-and-paste object lists from the Query Tool to the MAST SDSS products interface. A cookbook thread is provided.

Getting Started: Products, Access, User Groups

Users' Groups

All users should sign up for the SDSS Users' group, for time-critical user information from the SDSS about software upgrades or scheduled downtime. Users are encouraged to sign up for the SDSS Users' Forum for useful information exchange between users.

Available SDSS Data Products

Image and Spectroscopic Parameters (Object Catalog data):

- **Image Parameters:** Properties and profiles of all detected objects: positions, magnitudes, sizes, shapes and more (300 attributes per object).
- **Spectroscopic Parameters:** Redshift, line identifications and spectra-based classifications. (30 attributes per object).

Color Images and Plots of Spectra:

- Three-color composite images
- Flux vs. wavelength plots with spectral features identified, and other notations overlaid.

Image Pixels and Spectroscopic Pixels:

- Photometrically and astrometrically calibrated images in five wavebands (**corrected frames** with 0.4 arcsec pixels; binned images of the sky with 1.6 arcsec pixels, and objects removed.)
- Cut-out pixel maps, called **atlas images,** surrounding each object detected in the images.
- Maps of regions (mask images) which could not be used for science surrounding bright stars, bad columns, and other defects.
- Flux- and wavelength-calibrated spectra in the range of 3900-9100 Angstroms; 4096 samples at R=1800 (resolution).

Interfaces

There are multiple gateways to the public SDSS catalogs and data products. Researchers may want to start with the web-based MAST interface, and then download the SDSS query tool for larger and more advanced queries. The data products useful for scientific and display purposes are available through either the MAST catalog interface (select the html display of results and mark the objects for data retrieval) or more directly, with the appropriate catalog information copied from either the MAST SDSS catalog interface or the SDSS Query Tool, through the MAST data products interface for images and spectra

The skyServer interface taps into the same catalogs, but provides a more graphical interface to those catalogs, and is designed to be more useful to the public.

The MAST interface provides the user with the capability to search the catalog by position, and then, based on the query results, request additional data products. The more sophisticated data-mining queries must be submitted through the SDSS Query Tool. This Tool will allow the user to create a list which can be uploaded to the MAST data products interface for the data products associated with objects in the query results. The SkyServer interface provides an alternative interface to the public and the education community.

SDSS Early Data Release (EDR)

The available data products include: a searchable catalog containing the detected objects and their associated image and spectral parameters or attributes, 3-color pictures in JPEG format, data images in FITS format, and spectra in both GIF and FITS format. The EDR covers about 462 square degrees of sky.

SDSS Contributed Data Products

This page provides access to images, spectra, catalogs and catalog papers related to SDSS results in addition to SDSS publications.

1. SDSS Unusual Broad Absorption Line (BAL) Quasars
2. SDSS Quasar Target Selection Algorithm
3. SDSS Quasar Catalog paper and catalogs: this is the preferred source of quasar data, preferred over the EDR catalog itself.
4. Composite Quasar Spectra
5. USNO 40 Catalogued Stars
6. SDSS Galaxy Luminosity Function fits

Composite Quasar Spectra From the Sloan Digital Sky Survey

– 44 –

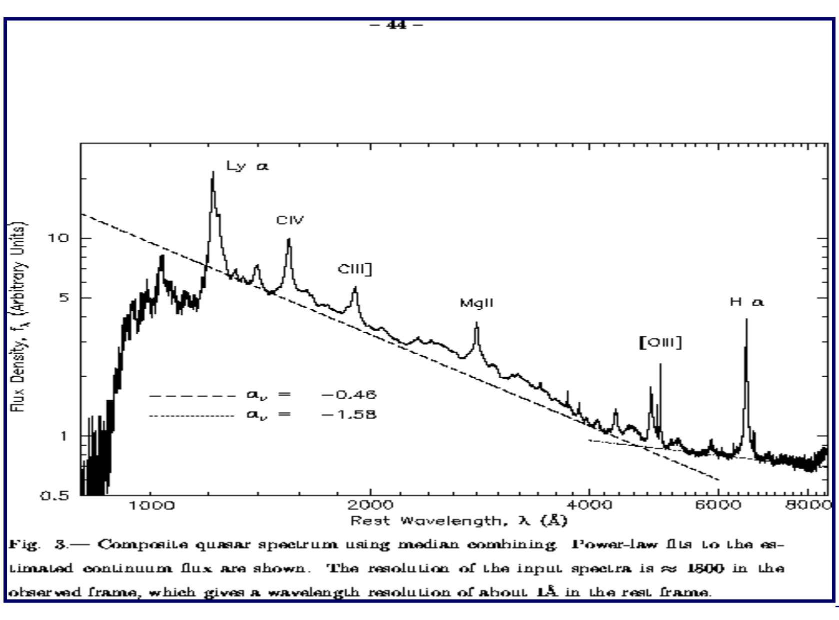

Fig. 3.— Composite quasar spectrum using median combining. Power-law fits to the estimated continuum flux are shown. The resolution of the input spectra is ≈ 1800 in the observed frame, which gives a wavelength resolution of about 1Å in the rest frame.

This is a composite quasar spectrum created by combining over 2200 individual SDSS quasar spectra. The flux density value at each bin is the median value of all of the spectra which cover the wavelength in the quasar rest frame. The quasar sample spans a redshift range of 0.044 <= z <= 4.789, and an absolute r' magnitude range of -18.0 to -27.7.00. The input spectra cover an observed wavelength range of 3800 - 9200 Å at a resolution of 1800. The median composite covers a rest wavelength range from 800 - 8555 Å, and reaches a peak signal-to-noise ratio of over 300 per 1 Å resolution element in the rest frame. Over 80 emission line features are identifiable in the spectrum (Vanden Berk et al. 2001, AJ submitted).

SDSS Composite Quasar in postscript

You may also download find an **ascii table** of the values for the composite QSO.

Vanden Berk Paper

The USNO40-calibrated **u' g' r' i 'z'** standard star catalogue can be found at the SDSS Primary Standard Star Network

The non-parametric fits to the SDSS Galaxy Luminosity Function Data by M. R. Blanton et al, AJ, 121, 2358, are available.

More MAST mission data now on-line
2002 February 27
All IUE, UIT, BEFS and VLA-FIRST data are now on-line on a RAID array. The response time for data downloads for these missions should improve significantly. Data for missions HUT, WUPPE, TUES, and Copernicus were already on-line. HST and FUSE data remain on DADS and response times for data download for these two missions are not affected. EUVE data are held at HEASARC and this data is also not affected.

Name Resolver Option Available in Cross Correlation search
2002 January 15
The cross correlation search option available from the top MAST page now allows a choice of NED or SIMBAD for resolving user-specified target names. (The previous version only used SIMBAD.)

New MAST/ADS Data Links
2002 January 11
The ADS data links to data archived winthin MAST have been revised. Now a link to a single MAST page is shown which displays all the known MAST references for a single bibcode. (See 1995ApJ...449..488R as an example.)

New Interface for SDSS EDR Quasar Data
2001 December 3
A web-based search and spectra retrieval interface for the SDSS EDR Quasar catalog and spectra, is now available at http://archive.stsci.edu/sdss/quasars/. The interface is based on a generic MAST interface we are developing and comments and suggestions, as always, are welcome at archive@stsci.edu.

New Plotting Option Offered in MAST Scrapbook
2001 October 18
A new option for coplotting multiple spectra and adjusting plot scales is now available in the MAST scrapbook.

The sdssQT User's Guide

This document is intended to guide novice users of the SDSS public release data through the steps necessary to obtain and understand the data.

The survey, including strategy, photometric and spectroscopic characteristics, is described at the STScI MAST interface site. The MAST site is intended for users who wish to make only basic queries, such as those centered on, or limited by, sky coordinates, object type, simple magnitudes, or colors ONLY. The capabilities and limitations of this method are explained in the Use Mast or QT? section of this site. More complex queries require use of the science archive query tool (sdssQT), a Tcl/Tk application allowing SQL (Structured Query Language) type queries. **Description and instructions for this tool are found from the links at the top of this page.**

In order to use the sdssQT effectively, users must understand the different classes and object parameters stored in the database, and their relations to one another. The data model and parameters are described from the *Data Parameter* link at page top. Users will also need at least a basic understanding of SXQL (the Science Archive version of SQL); examples and help are provided under the *Using sdssQT* menu above.

For **help** on this site, please visit the Help Page. If you have any questions or comments, or notice any errors, *specifically about this user's guide*, please email the author of this document:
Roy Gal, rrg@pha.jhu.edu.

Class Overview

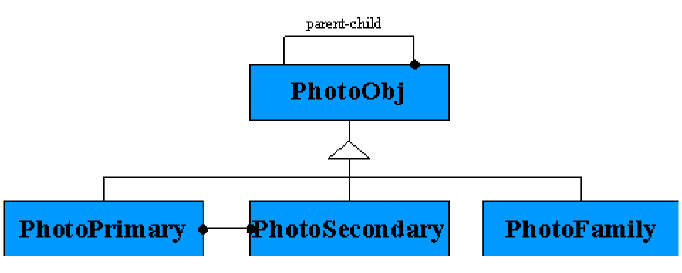
Since the Science Archive is based on an object-oriented database, we have **classes** for each object, not **tables** as opposed to objects in a relational database. The classes are linked to each other either by **inheritance** or by **association**.

Inheritance is a way to specialize a class. Every data member of the base class is also member of the inherited class, but the inherited class may have additional data members. In the schemata below, inheritance is represented by a large empty arrowhead between the classes.

Associations link classes to one another. There are one-to-one, one-to-many and many-to-many associations. Through the associations one can access the data members of the associated class through the dereferencing operator '.' (dot). In the schemata below, associations are the thick lines connecting classes, -to-many links represented as blobs at the corresponding end.

Photometric Survey Objects

Objects of the photometric survey are all members of the base class **sxPhotoObj**. It is specialized into primary, secondary and bad objects:

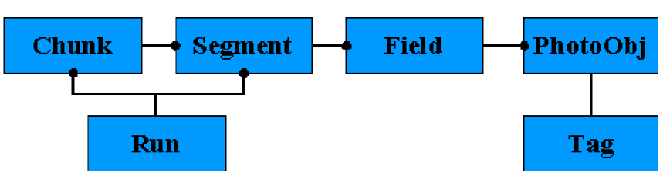


PhotoPrimary objects are the primary survey catalog objects. Secondaries are secondary observations of objects (in the overlap area of the stripes). More than 10% of all objects have secondaries. There is a many-to-many link between primary and secondary objects. A secondary object may be associated to more than one primary if the secondary observation is of a bad quality and could not be resolved into two or more objects. And obviously primaries can have associations to several secondary observations.

The link of the PhotoObj to itself is the one-to-many parent-child link. Each object may belong to a family of objects (the deblender was at work here).

Bad objects are kept only if they are member of a family, for example spiral arms of a galaxy that have been deblended.

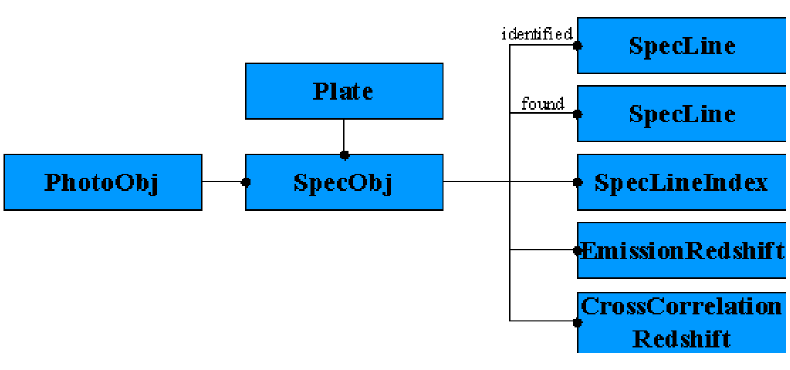
Photomeric Survey Structure



The photometric survey is strucutred into Chunk > Segment > Field > PhotoObj, all linked by a one-to-many association. The Tag object contains the coordinates and model magnitudes of each object along with the object flags. Each PhotoObj object has exactly one Tag associated with it through a one-to-one link.

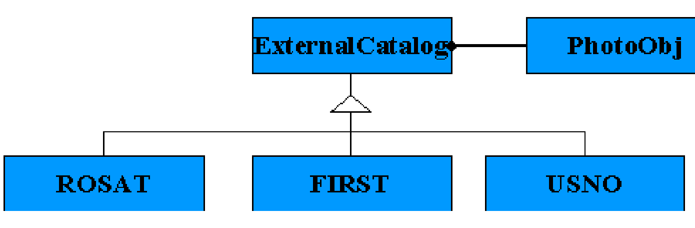
Spectroscopic Survey Objects

The spectra are taken on spectroscopic plates, to each of which we have a corresponding sxPlate object. The sxSpecObj objects correspond to each spectroscopic survey object, and they have associations to the found and identified spectral lines as well as the emission and cross-correlation redshifts measured. Spectral line indices are not included yet but a placeholder is there.



External Catalog Objects

Some objects are identified in external catalogs too and have some extracted quantity in those catalogs. There are links to ROSAT, FIRST and USNO catalogs.



Additional Classes

The **Profile** class has a one-to-one association to the PhotoObj class and contains the profile bins for each object. This has been splitted off the main PhotoObj to save space.

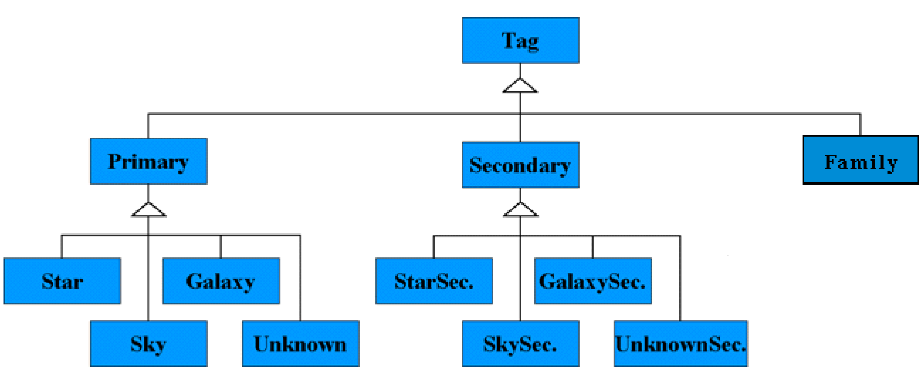
The **SDSSConstants** class contains global survey constants of interest.

There are two placeholder classes for photometric redshifts to come.

Tag Objects

Tag objects have been introduced as a lightweight object to actually do the database searches on. Most queries will have a cut either in coordinate or in color space so we suggest querying on a Tag object to enhance query speed significantly.

The Tag objects are specialized using inheritance into several classes depending on their type:



Tag objects are chosen based on the following selection criteria:

```
      if ( ( ( ( obj->status & AR_OBJECT_STATUS_FIRST_FIELD ) && gotFirst_ )
||
            ( !( obj->status & AR_OBJECT_STATUS_FIRST_FIELD ) && !gotFirst_ )
)
           && (  obj->status & AR_OBJECT_STATUS_PRIMARY  )
           && (  segH->status == AR_SEGMENT_STATUS_PRIMARY  )  ) {

             ---> sxPrimary

       if ( ( obj->objc_type == AR_OBJECT_TYPE_STAR) ) {

                ---> sxStar

        } else if ( ( obj->objc_type == AR_OBJECT_TYPE_GALAXY) ) {

                ---> sxGalaxy

        } else if ( ( obj->objc_type == AR_OBJECT_TYPE_SKY) ) {

                ---> sxSky

        } else {

                ---> sxUnknown
        }

      } else if (
           ( ( ( obj->status & AR_OBJECT_STATUS_FIRST_FIELD ) && gotFirst_ )
||
            ( !( obj->status & AR_OBJECT_STATUS_FIRST_FIELD ) && !gotFirst_ )
)
           && (  obj->status & AR_OBJECT_STATUS_SECONDARY  ) ) {

             ---> sxSecondary

       if ( ( obj->objc_type == AR_OBJECT_TYPE_STAR) ) {

                ---> sxStarSecondary

        } else if ( ( obj->objc_type == AR_OBJECT_TYPE_GALAXY) ) {

                ---> sxGalaxySecondary

        } else if ( ( obj->objc_type == AR_OBJECT_TYPE_SKY) ) {

                ---> sxSkySecondary

        } else {

                ---> sxUnknownSecondary
        }

      } else {

             --> sxFamily
      }
```

Try to use the Tag object and its inherited classes whenever possible as your query object.

This standalone atlas image reader can be built in one of two ways:

```
1/ Simply type
        make
No survey environment is required. If your machine is little endian, add
        -DSDSS_LITTLE_ENDIAN
to CFLAGS in the Makefile. If you have a survey environment and have
setup dervish, but still want the fully standalone version, you'll either
have to unsetup dervish, or uncomment the lines
#DERVINC =
and
#DERVLIB =
in the Makefile before building read_atlas_image

2/ Setup dervish, and type
        sdssmake

I'd recommend that you do a
        make clean
before switching between these two ways of building read_atlas_image. You may
not strictly need to do so, but it's certainly a wise precaution.

Then, to write object 12's 2nd colour (i.e. r)'s atlas image (found in file
fpAtlas.fits) to file ai.fits, you'd say

        read_atlas_image -c 2 fpAtlas.fits 12 ai.fits

I don't expect that many users will actually want to use the
read_atlas_image executable (although it is perfectly functional). The
main use of the product will probably be to link into custom built
executables that need to process atlas image data. I believe that the
code should be easily reused for this purpose.

The standalone programmes read_mask (reads fpM files) and read_PSF
(reads psField files) are similar; build instructions are identical.

To read the z' INTERP mask from from run 1336, column 2, field 51 you'd say:
        read_mask /u/rhl/data/1336/objcs/2/fpM-001336-z2-0051.fit 1 foo.fit
The resulting file (foo.fit) would be a char FITS file, with a 1 in each
pixel that was interpolated. The bitplanes are:

   typedef enum {
      S_MASK_INTERP = 0,           /* pixel's value has been interpolated */
      S_MASK_SATUR,                /* pixel is/was saturated  */
      S_MASK_NOTCHECKED,           /* pixel was NOT examined for an object */
      S_MASK_OBJECT,               /* pixel is part of some object */
      S_MASK_BRIGHTOBJECT,         /* pixel is part of bright object */
      S_MASK_BINOBJECT,            /* pixel is part of binned object */
      S_MASK_CATOBJECT,            /* pixel is part of a catalogued object */
      S_MASK_SUBTRACTED,           /* model has been subtracted from pixel */
      S_MASK_GHOST,                /* pixel is part of a ghost */
      S_MASK_CR,                   /* pixel is part of a cosmic ray */
      S_NMASK_TYPES                /* number of types; MUST BE LAST */
   } S_MASKTYPE;

with HDU _one_ corresponding to plane _zero_ (INTERP).  You can specify
these HDUs by name (e.g. OBJECT) or number (4).  With the -p flag, instead
of generating a FITS file, a description of each mask object as a set
of convex polygons is written in ascii to the output file; the format
should be obvious.  One caveat: the vertices of the polygons are the
pixel indices, so the boundaries pass _through_ the edge pixels, and
the quoted areas are not quite the areas of the polygons that include
all of the area.

The current version of this polygonal approximation code in fact generates
exactly one polygon per photo object, the convex hull.

To reconstruct the z' PSF (i.e. the 5th HDU) at the position
(row, col) = (500, 600) from run 1336, column 2, field 51 you'd say:
        read_PSF psField-001336-2-0051.fit 5 500.0 600.0 foo.fit
The desired PSF would appear as an unsigned short FITS file in foo.fit;
the background level is set to the standard `soft bias' of 1000.
If you want a floating image, change a line in the read_PSF.c; look for
        /* create a float region */

                        Robert Lupton (rhl@astro.princeton.edu)
```

SDSS Relevant Software

---

1. SDSS Science Archive Query Tool (sdssQT)

sdssQT v2.3.2 is available.

The SDSS Query Tool (sdssQT) is a Graphical User Interface (GUI) that provides the functionality necessary for SDSS users to prepare and submit simple or complex queries to the Science Archive. The current interface is a Tcl/Tk client application that allows you to connect to the SDSS Catalog Archive Server and run queries on the Catalog Archive. You will need Tcl/Tk version 8.0 or later installed on your machine, and have a "wish" executable in your path that runs a wish8.0 or later. Many platforms have this already.

Before you install, we strongly recommend that you join the SDSS Users' Group. This list will allow us to alert you to necessary upgrades in both software and documentation, as well as scheduled database downtimes. This list will only be used for such time-critical notification of users. The other group, the SDSS Users' Forum, is a bulletin board for SDSS scientists, and is open to all fellow scientists interested in the SDSS.

Download and install the sdssQT version 2.3.2, and don't forget the tool that converts bin to FITS binary tables (including instructions for compilation and installation.) For the EDR, we have made available the latest fully functional version of the Query Tool, which is called ``sxQT" or "sdssQT".
The official SDSS QT guide is available below. You need JavaScript enabled to read the documentation.

SDSS QT Early Data Release User's Guide : last update Jan 28, 2002

You may need a complete description of the SDSS database structure and classes: sxQT documentation for classes and database descriptions

You can check if Tcl/Tk is installed with a "which wish" command. Tcl/Tk can be downloaded from the following site(s):
Tcl/Tk 8.0
Tcl/Tk 8.3

A Tcl/Tk installation caveat: the default tcl/tk installation names the "wish" executable with a version number, e.g. "wish8.0". The SDSS Query Tool script looks for an executable with just the name "wish", so the user needs to add a logical link "ln -s wish8.0 wish" in the bin directory where the executable is installed.

Start-Up hints from a novice for a novice:

1. The executable brings up a blank square. To start the action, use the Connect menu option.
2. The server requires a username password combination. Use username *guest* and password *archive*.
3. Select the FermiEDR as the server.
4. Try a File>Load Examples>Simple Tutorials for a sample of how the tool works. These tutorials can be modified with guidance from the SDSS QT and database documentation.
5. Output can be directed to a local file, remote file or remote socket, with some format options.

---

2. readAtlasImages

SDSS standalone programs to read fpBin, fpAtlas, and fpField files

- README file; ASCII
- file. Shift-click to download.

Search across missions cross-correlated with catalogs

Target Search Help

A target search utility is provided on most of the MAST mission pages. A user may enter either a SIMBAD compatible target name or coordinates. Target names will be resolved by SIMBAD to obtain the appropriate coordinates. Coordinates will also be sent to SIMBAD where they will be used to determine the coordinates of the closest object (up to 10 arcminutes from the input coordinates). In both cases, the returned coordinates of the found object are then used to perform the database search. If the user needs an explanation of the search results, help is available from the search results page.

User-entered target names must be recognized by SIMBAD. If the target name is not found, consult SIMBAD's Dictionary of Nomenclature of Celestial Objects. If the the object names is not recognized by SIMBAD, or there is some other problem with SIMBAD, then the search will fail and (in some cases) the standard mission search page will be displayed.

User-entered coordinates may be entered as either "hr min sec deg min sec" or as "ra dec" in decimal degrees. In either case, THE SIGN OF THE DECLINATION MUST BE SPECIFIED or the search will fail.

Using the standard mission database search form will allow the user more advanced searches. It is normally accessible from the "Data Search" link on the main mission page.

Getting Started

The Hubble Space Telescope (HST) Data Archive (HDA) contains science data from all completed HST observations and calibration files. As of March 1, 2001, the archive contains over 7 Terabytes of data, for a total of more than 230,000 science exposures. In addition to all the science data sent to observers and all the calibration reference files, the archive contains engineering files that may be useful for diagnosing some questions about observations. As data are archived, information about observations and the targets is extracted from the headers of the data files and stored in an on-line catalog.

HST data become available to the astronomical community (or to any individual with the interest and hardware capabilities required to analyze the data) upon the expiration of a proprietary period. Most general observer (GO) and guaranteed time observer (GTO) observations have proprietary periods of a year, but some observations have shorter or longer proprietary periods. Nearly all calibration observations are made public immediately upon receipt. The archive catalog contains information about all observations that have been made with HST. Access to the HDA is open to everybody but registration is necessary. All public data can be retrieved from the HST archive. Proprietary datasets may be retrieved by GOs and GTOs with the appropriate authorization (contact the archive hotseat at archive@stsci.edu).

There are two different ways to access data in the HDA: StarView and a World Wide Web (WWW) interface. StarView is an astronomical database browser and research analysis tool. Developed in Java, StarView provides an easy to use, highly capable user interface that runs on any Java enabled platform as a stand-alone application. More details and instructions on how to install StarView are available at the StarView Home Page. The HDA can also be accessed via an interface available from the archive WWW page. Most users will find the WWW interface more convenient to use, as it does not require any client-server software installation and can be accessed by any WWW browser. Note, however, that the WWW interface does not provide all the functions of StarView as regards HST data.

STScI automatically processes and calibrates all data received from HST via a so-called "pipeline." Pipeline processing assembles data into datasets, calibrates the data according to standard procedures, and stores both uncalibrated and calibrated (for some instruments) datasets in the HDA. Almost all the files in the HDA are stored in FITS format. Most observations have multiple image planes; for example, WFPC2 images usually have four planes, one for each CCD chip. HST data can be analyzed or recalibrated using the Space Telescope Science Analysis System or STSDAS. Detailed information can be found at the STSDAS WWW page.

Search and Retrieval

HST data can be found using the HST search form to query the Hubble Data Archive (HDA) catalog. The catalog is stored in relational database tables at STScI, but users do not need to know about databases or Structured Query Language (SQL) to browse through it. The two possible user interfaces are the java-based StarView application and the web-based HST search page. These interfaces take care of the technical details and makes searching the catalog quick and easy. Both interfaces take the user's specifications - e.g., right ascension and declination, filter, exposure time, release date, etc. - and search the database for exposures that match them. They then return the search results in a table format or one record at a time. (One can save these results to a file.) See the how to search page for more information.

Once the user has found HST data he/she wants to retrieve, he/she will need to register for an archive account. Registration is open primarily, but not exclusively, to astronomical researchers who can make scientific use of HST data. HST data are intended for professional astronomical data reduction and analysis systems like IRAF, MIDAS, IDL, etc. Before registering, users should read about our retrieval policies.

Registration forms are available on-line or by contacting the HST Archive Hotseat. We use this information to contact users about the status of their retrievals, and about new developments in the archive we think they should know about.

Once users are registered, they will have an archive retrieval account with an associated username and password. After searching the HDA with one of the two available interfaces, the datasets of interest can be marked for retrieval with the `Mark' button and then submitted for retrieval to DADS, the HST Data Archiving and Distribution Service. Different retrieval options are available, including ftp of the data to the user's home machine and transfer (for public data only) to the archive staging disk. DADS will send email when the request is completed.

What's New for HST during last year

More MAST mission data now on-line
2002 February 27
All IUE, UIT, BEFS and VLA-FIRST data are now on-line on a RAID array. The response time for data downloads for these missions should improve significantly. Data for missions HUT, WUPPE, TUES, and Copernicus were already on-line. HST and FUSE data remain on DADS and response times for data download for these two missions are not affected. EUVE data are held at HEASARC and this data is also not affected.

Larger Staging area for HST and FUSE data
2002 February 27
The staging area for HST and FUSE data retrieved with the HOST option has been significantly increased to around 500 GB from 27GB.

Name Resolver Option Available in Cross Correlation search
2002 January 15
The cross correlation search option available from the top MAST page now allows a choice of NED or SIMBAD for resolving user-specified target names. (The previous version only used SIMBAD.)

New MAST/ADS Data Links
2002 January 11
The ADS data links to data archived winthin MAST have been revised. Now a link to a single MAST page is shown which displays all the known MAST references for a single bibcode. (See 1995ApJ...449..488R as an example.)

Magellanic Cloud Planetary Nebulae Data Sets now Available
2001 November 15
HST prepared datasets of the Magellanic Cloud Planetary Nebulae are now available.

HST Literature Links Update
2001 November 13
The HST reference database table entries (and ADS data links) are now complete through the first half of this year.

New Plotting Option Offered in MAST Scrapbook
2001 October 18
A new option for coplotting multiple spectra and adjusting plot scales is now available in the MAST scrapbook.

Exposure time searches offered for WFPC2 Pointings
2001 September 27
The WFPC2 Pointings search form now allows searches to be performed on total exposure times. See the pointings help page for more information.

OTFR Implemented for NICMOS Data
2001 September 26
As of today, all requests for archived NICMOS data will utilize the On-the-fly Reprocessing (OTFR) system.

New Archive Search Service for Wide Field Planetary Camera2 Observations
2001 August 24
The Pointings Search Interface allows users to explore a new table set we have created for WFPC2 pointings. We developed this table by defining a "pointing" for the WFPC2 to be a location in the sky circumscribed by a circle with a radius of 40". Then we assigned each WFPC2 observation to a pointing. We then compiled a table which described each pointing: the number of "u", "b", "v", "r", "i", and "narrow-band" observations at each pointing, the number of unique bands, the total number of exposures, and the number of days between the first and last exposure. Each pointing is also identified with a galactic and ecliptic latitude.

HST Literature Links Update
2001 August 22
The HST reference database table entries (and ADS data links) are now complete through the year 2000.

FOC Images added to MAST Scrapbook
2001 August 1
Representative spectra from the HST Faint Object Camera (FOC) have now been added to the MAST scrapbook.

New site available for FOS Calibration/Information
2001 July 11
STSDAS software for applying improved calibrations to FOS data plus a slew of other new FOS features (on-line material, etc.) is now available from the FOS POA site at the ESA European Coordinating Facility. See their web site for more information.

Data Characteristics Plots Updated
2001 June 13
The MAST Data Characteristics plots have been updated to include the FUSE, TUES, BEFS, and SDSS missions.

Target Search Error
2001 June 12
An error was discovered in the target search available from the main MAST page. Searches would fail for object names containing special characters (such as a "+" symbol as in BD +28 4211). The error was fixed on the above date.

Implementation of Redesigned MAST Web Site
2001 June 4
The MAST redesigned web site is now online. The new dynamically-generated pages feature a common page layout, options for site-wide index searches, mission-specific target name searches, easier site navigation, and a printer-friendly page display option.

OTFR Pipeline Delivered
2001 May 15
All STIS and WFPC2 archive data are reprocessed upon retrieval from the original telemetry, with the most optimal reference files and software available.

Updated Literature References
2001 April 9
The HST literature references (and ADS data links) now include papers from 1997 and early 1998.

Frequently Asked Questions

Proposal

- ***Who do I contact for help with proposal preparation?***
  STScI is maintaining a hotseat from 9:00am to 5:00pm Eastern Time at 410-338-1082 or (toll-free in the U.S.) 800-544-8125, and e-mail to help@stsci.edu. There is also the ST European Coordinating Facility, at 49-89-320-06-291, email: stdesk@eso.org, as well as a list of contacts in Appendix A of the Call For Proposals.

  If you have a question regarding Archive facilities used in preparing your proposal (such as duplication checking or the Planned and Archived Exposures Catalog), please contact us at archive@stsci.edu.

- ***Can I do duplication checks on the web?*** NEW
  You can use the web-based duplication search to check your proposals for duplication conflicts. Duplication checking is still available via StarView.

Retrievals

- ***How do I get the latest FOS calibrated data?***
  Improved calibrations for FOS data are available using STSDAS software available from the www.stecf.org web site. Additional FOS information is also available from this site.

- ***Why can't I log into archive.stsci.edu as `guest`?***
  The archive guest account has been discontinued. You can install StarView6 on your machine. You can also use the Web form. If neither of these approaches is sufficient to meet your needs, please let us know.

- ***How can I retrieve HST data?***
  You'll need to register for a retrieval account. Your retrieval account will give you access to any science, calibration, or engineering data in the Archive. PIs need a special authorization attached to their retrieval accounts which allows them to retrieve proprietary data from their own proposals; see this answer for details. You can retrieve public data using one of the following options:
  - by installing and running StarView6 at your site;
  - by using the HST Archive Search on the Web;
  - The archive guest account has been discontinued.

  The data can be retrieved either to the staging disk using the `HOST` option or directly to your own site using the `NET` option. Both options are now available via StarView6 or the HST Archive Searches on the Web.

  If you use the `HOST` retrieval option, DADS will retrieve the data to the staging disk of the host machine listed in your retrieval completion message.

  If you use the `NET` retrieval option, you will need to specify the machine address, login, password and directory where you wish the data to be retrieved.

  > DADS will ftp the data directly to a directory on your computer. (Note that we protect your destination information when it is transferred *to* us with the same kind of secure-web mechanism that is used by commercial sites conducting online commerce.)

  Note that the `NET` option is the only one available to retrieve proprietary data across the internet.

  If internet transfers are not feasible, both public and authorized proprietary data can also be retrieved to tape-- just use the `TAPE` retrieval option. We will ship it to the address given in your account registration.

- ***I am the PI on proposal xxxx. Can I use StarView or the Web to retrieve my data?***
  We're happy to tell you that you can! You can have your retrieval account set up so that you will be able to retrieve proprietary data from those proposals directly to a directory on your home machine.

  Just send an email to archive@stsci.edu. Please note the proposal id's, and designate any others who you believe should have access to the data.

  You can't retrieve *any* proprietary data to the Archive hosts; it has to be delivered to your machine using the `NET` option or to tape using the `TAPE` option.

  You can also designate your co-investigators for this privilege.

- ***I am the PI on proposal xxxx. Why can't I retrieve the data?***
  You can, but you'll need to let us know you want it. Currently, PIs do not receive automatic electronic access to their data. (This is a technical limitation, not a policy.) If you are the PI and want electronic access to your proposal, contact *archive@stsci.edu* and let us know the proposal ID and your archive username. We will attach the proper access privileges to your account to allow you to retrieve this data electronically.

  You can also authorize co-investigators and co-workers to have electronic access as well. Just tell us the proposal ID and the names and archive usernames of those to whom you wish to grant access. (If they don't have accounts, or you're not sure if they do, then let us know their email addresses to we can help them set up accounts for access.)

  Authorization may be set up only on a per-proposal basis; we cannot restrict access to certain data within the proposal.

- ***How do I get permission to retrieve my proprietary data and documents?***
  We ask that the PI send us an email (to archive@stsci.edu). In that email, note the proposal id's, and designate any others who you believe should have access to the data.

Once an individual is authorized for a particular proposal, they have access to all proprietary data in that proposal only.

Be sure to use the `NET` retrieval option!!

If while retrieving your data you get a message saying that the data are still proprietary, one of the following has happened:

  - You are trying to retrieve the data to the Archive Host staging disk. The staging disk is an anonymous FTP area, so we can allow only non-proprietary data to be written to it. Have the data sent directly to your disk or sent to you on tape instead.
  - We made a mistake and didn't properly authorize your account. This may be particularly true if you (for some reason) have more than one archive account.
  - The data are under restriction, which means that they were found to duplicate planned or existing proprietary observations, and an access restriction has been placed on them until the data with which it conflicts is released.

- ***I forgot my password***
  Don't worry, it happens to the best of us. Just call the Archive Hotseat and we'll reset it for you.

- ***How long should a retrieval take?***
  The retrieval time depends on a variety of factors:
  - the type of data in the request. Some older data is stored offline and requires an operator's intervention.
  - the size of the request- the larger the request the longer it takes, both to move the request up the queue , and to retrieve the data.
  - the number of requests in the system at the time.
  - the destination of the request. The internet connections between STScI and some sites, especially those overseas, is sometimes a significant source of delay.

  If everything is running smoothly, expect a median turn around time of a few hours. If it takes more than one day, and you don't think any of the factors listed above are playing a significant role, please contact us.

- ***When I submit a request, it fails immediately, telling me my host password contains forbidden characters...***
  There are 5 characters that are forbidden:
  ( ) * " /
  In order to successfully submit a request, you will need to change you password to something not containing those characters. We hope to fix this eventually, as it can be a significant inconvenience.

- ***I submitted a retrieval, but never got a notice that my request was submitted and queued...***
  DS may be down, so it's not reading its mail. The way a retrieval works is that StarView emails the request to DADS. (If you have your mailer set to automatically log outgoing mail, then you'll see these requests, in their encrypted form, in your outgoing mail folder.) DADS then reads its mail and puts your emailed request onto the retrieve queue.

  If DADS is down, or is not reading its mail for some reason, then your message will be held in the folder until DADS comes back up, when it starts reading its mail and queueing requests again. That's when you'll be notified.

- ***I tried retrieving some data, but the staging disk is full...***
  Fortunately, this doesn't happen as often as it used to, since we installed a bigger staging disk on one of the Archive host machines. (You can check its capacity to be on the safe side.) However, if it does, you can either contact the Hotseat and we'll see if we can do anything to make room (usually by contacting other users and asking them if we can delete their data), or by resubmitting the request and having the data delivered directly to a directory on your home machine (`NET` option), rather than onto the staging disk.

- ***My request failed. Now what do I do?***
  If it failed for a reason you can identify (such as a mistyped password/directory/login or no space left on destination device) go ahead and resubmit the request with the necessary alterations. Once a request fails in DADS, it is dropped from the system.

  We do not resubmit failed requests for users, you will need to do that yourself.

  If the failure occurred for a reason that isn't clear, contact the Archive hotseat with a description of the failure and we will investigate.

- ***What does this error message mean?***

  `General FTP error`: Transfer failed due to ftp errors. If it isn't clear from the code and comments what caused the error, and it continues to occur, please contact us and we will investigate.

  `File not found`: Usually a result of a hardware error on our end. You can resubmit the request and usually the problem goes away. If it doesn't, please contact us.

  `File not processed`: If you receive this error and cannot subsequently retrieve the data, please let us know.

  `Dataset does not exit`: This can result when you have submitted a request using the customize retrieval options, or have edited your request file. Double check that there are no errors in the filenames, classes and extension you requested. If you are certain that this file should exist, please contact us and we will look into it.

- ***I submitted a request two days ago, and it hasn't finished yet.***
  Chances are it won't finish. Retrievals may have crashed and taken your request with it. We will contact you when that happens, but sometimes we may not be able to.

  DADS retrieval times are dependent on the size of your request, the destination you specified and the number of requests in the system. A median retrieval turnaround time is a few hours, so if your request has taken more than a day without you getting a completion message, contact the Archive Hotseat and ask about your request. It has been our experience that users outside the United States sometimes experience longer retrieval times.

- ***How can I find out how my retrieval is doing?*** UPDATED
  Via the web, you can check the status using a simple tool at
  http://archive.stsci.edu/cgi-bin/reqstat

- ***I retrieved some data and got a notice that it was ready. Where is it?***
  If you selected the `HOST` option in StarView or on the Web then the data was retrieved to the staging disk of stdatu.

  It has a "lifetime" on that disk of about 3 days.

  Use anonymous FTP to get your data (ignore the `/stdatu/dads_stage` part of the pathname).

  If you selected `NET` as the media option, then the data will have gone to the node name and directory you gave to Starview as the destination directory.

- ***I don not want the data I just requested. Can you kill this request?***
  Once the request has been queued, we can't kill it-- at least, not without bringing down retrievals completely.

- ***Can I get the data in (GIF/JPEG/whatever) format?***
  The data are delivered from the Archive in multigroup Flexible Image Transport System (FITS) format only. We currently do not support conversion to other formats; you will have to do this yourself.

- ***How do I display data in FITS format?***
  There are various FITS readers available. For example SAOimage (ds9), which can be retrieved via anonymous FTP from sao-ftp.harvard.edu in the directory /pub/rd/ds9, runs on various systems. More information on HST data and data analysis software is available on-line (in particular, see the HST Data Handbook).

- ***I know I have an account on stdatu, but I can not log into it any more...***
  The Archive guest account has been discontinued. Users should either:

  - Install StarView6 at their home sites
  - Use the Web tools for searching the catalog and retrieving data

  If neither of these options meet your needs, please contact us at archive@stsci.edu.

- ***I don't need the whole dataset. How do I retrieve just one file extension?***
  With the current OTFR system, this is not possible. You will get a `Dataset does not exit` error. For instruments not using On The Fly Calibration or Reprocessing, it will still work.

  This option will eventually be reactivated.

  We recommend not using it in the meantime.

  As of May 15 2000, ST ScI stopped archiving calibrated WFPC2 data. For datasets archived after this date, selecting a calibrated file extension will return a dummy file containing no data. Use the On-The-Fly Calibration option to retrieve calibrated data for WFPC2 datasets archived after May 15 2000.

Searches

- ***I need to recalibrate some data. Can I retrieve the calibration files?***
  Yes. In Starview, for each instrument, there is a calibration screen that will show you what files the dataset was calibrated with, and which files you should use if you are recalibrating. Each of these screens has special buttons to mark the used or recommended calibration files for retrieval.

  If you already have the names of the files you want, then you can retrieve them directly. Go directly into the Retrieval screen through the Commands menu and use the "Add dataset by name" or "Add datasets from file" options. In the "File Options" screen, just press the "Calibrated" (or "OTFC" for STIS or WFPC2) button. That will ensure you get the right files.

  Via the Web, select the appropriate choice from the Retrieval Options page: "Best Reference" or "Used Reference" files.

  To search for specific calibration files, you will need to know the names of the files and search for and retrieve them using the Dataset List Search page.

- ***How do I find observations of an object by name?***
  You can try entering this in the "Target name" field of a search screen, but the target names in our database are chosen by the proposer, so they might be a little (or a lot) different than you might guess.
  The best way to search for a specific (fixed) target is to use the "Get

Coordinates"/Resolve button. Press this button and a window will pop up asking you for a target name. When you enter a target name and search, it will resolve the target names into RA and Dec through SIMBAD or NED. It will then enter the target's RA and Dec on the StarView screen, along with a 10-arcminute search radius (which you can change, if you want). (If you do a lot of extragalactic work, you can choose the NED resolver instead of SIMBAD.)

For solar-system targets, you may still need to search by target name. In this case, it would be wise to wildcard the target name. For example, to search for observations of Jupiter, enter `*JUP*` into the target name field. Also, you can constrain your search to solar-system proposals by entering `Solar System*` in the "Description" field, if there is one on the screen. (Note the wildcard!)

- ***How do I find all the observations for a class of objects (like Seyferts?)***
Specify a target description. Pull down the "Help" menu and select "On Targets". This help topic will show you how to search for observations of classes of objects. There is also an up-to-date list of target descriptions currently in the HST Archive.

- ***Can I use StarView or the Web to cross-correlate a list of my targets?***
Both StarView and the web offer cross correlation.
There are instructions on how to use the StarView cross correlation in the online StarView help documentation.

Cross correlation is also available on the web at http://archive.stsci.edu/search/. There are help texts that describe how to use this function.

Starview

- ***Java-based StarView 7 Released*** NEW
Developed in Java, StarView version 7 provides an easy to use, highly capable user interface that runs on any Java enabled platform as a standalone application.

You can download and install it. It requires Java 1.2 or higher to run, but it is recommended that users download StarView 7 with the optional Java 1.3 included. (Note Java 1.3 is up to 30% faster!)

The old StarView 5.4a and 6 have been discontinued. All x-windows and crt-versions are no longer functional. Users will need to switch to StarView7.

- ***Does StarView run on platform X?***
StarView7 needs a system that has a Java 2 Runtime Engine. You will need to make sure that you have a version of Java that is 1.2 compliant. See download and install links for more information.

- ***Can I install the StarView7 software on my machine?***
Yes. StarView7 is available from the web.

- ***Can I get the source code for earlier versions of StarView and compile it on my machine?***
Please use StarView7.

- ***How do I run StarView?***
You can install StarView7 and run it from your home site.

- ***I need to run StarView on archive.stsci.edu. Why can I not login with my archive user id and password?***
The Archive guest account was been discontinued. Users should either:

  - Install StarView7 on their home sites
  - Use the Web tools for searching the catalog and retrieving data

If neither of these options meet your needs, please contact us at archive@stsci.edu.

- ***When I try to start StarView5.4, it crashes immediately. What is wrong?***
StarView 5.4 is now obsolete. Please install StarView7.

Documentation

- ***Where can I get the Archive Manual?***
  - *The **Archive Manual** is available on-line.*
  - *The **HST Data Handbook** can be found here.*
  - *You can get these via anonymous FTP from:*
    - *ftp.stsci.edu, in the directory* `archive-html`
    - *archive.stsci.edu, in the directory* `pub/manuals`
  - *You can also use our document request form to order printed copies (they're free), or just contact the Archive Hotseat.*

- ***How do I find out the latest versions of the Manual?***
We will keep the most up to date manual we have available on-line

- ***Is there an Archive Newsletter?***
Yes. The electronic newsletters provide information about the various archives supported by the Multi-mission Archive at STScI (MAST). In addition to HST data, MAST also provides support for VLA First, IUE, Copernicus, and EUVE data. Data from the FUSE, Astro-1 and Astro-2 missions for the UIT, HUT, and WUPPE instruments will be added in the future.

It is sent out electronically to a distribution list. You can also read it on-line.

Paper Products

- ***I had some observations made recently, but I haven't yet received a tape...***
As of August 1, 2000, we are no longer generating tapes for proposals. If you wish to have a tape of your data, please submit a retrieval request as you normally would, and use the TAPE retrieval option.

- ***Can I have multiple copies of a tape made for my collaborators?***
Because of the volume of data that we handle, we can only make one copy of the data. However, see the "How_can_I_retrieve_HST_data_" question about PIs retrieving their own data for information on how to let your CoIs retrieve the data from the Archive directly.

- ***Can I get my tapes sent via a next-day carrier?***
All tapes are sent out via FedEx Next Day Air by default.

- ***How do I generate paper products myself?***
*We offer paper products electronically in PDF format. As of **August 1, 1999** we no longer manufacture hardcopies of the paper products, but will still provide them for extreme need cases. Please contact us if this is the case.*

Users will need to retrieve their paper products using the PDF Search Page

Files are password protected (unless the proposal is a calibration program) and users will need their archive name and password to access documents (as well as authorization to access the proposal). This interface is not intended for general archive users but specifically for PIs of HST programs.

You can also generate paper products from your data using a task in IRAF/STSDAS called pp_dads.

ASCII Catalogs

- ***How often are the catalogs updated?***
The AEC is updated monthly. Check the file README.AEC for the date through which the AEC is complete.

The PAEC and proposal catalogs are usually done once or twice each proposal cycle.

- ***Where do I find the ASCII catalogs, namely the AEC and PAEC?***
The ASCII catalogs are online at http://archive.stsci/hst/catalogs.html.

Data Reduction/Analysis

Hubble Space Telescope (HST) science data are stored in the HST Archive in FITS format. Information on the FITS header keywords in HST data files can be obtained from the keyword dictionary. Access to the archive is open to everybody but non-astronomers should be aware of the fact that HST data are intended for professional astronomical data reduction and analysis systems.

The Space Telescope Science Institute (STScI) supports dedicated software, the Space Telescope Science Analysis System (STSDAS), for reducing and analyzing HST data. This software works within the Image Reduction and Analysis Facility (IRAF).

Specific details about the format and content of science datasets can be found in the HST Data Handbook. For any questions about HST data reduction and analysis users should contact the STScI Help Desk at help@stsci.edu.

For several HST instruments improved calibrations, as compared to the calibrated files available in the archive, are possible with newer calibration files. These files can be retrieved for a given dataset using this interface. Note that with the release of On-The-Fly Reprocessing (OTFR) archive users can obtain WFPC2, NICMOS, and STIS data that are processed with the latest calibration files, software, and data parameters. The OTFR system calibrates data when processing a user's request for the data from the archive.

Improved calibration of FOS data using new STSDAS software is available from the www.stecf.org/poa web site, along additional FOS-related news, documentation, and activities.

The results of investigations with HST archive data are generally published in the scientific literature. All publications based on these data should carry an acknowledgment.

Proposal Support

The Hubble Space Telescope (HST) proposal process involves various steps, which are summarized below. For more details please check this page.

- Call for Proposals

  The Call for Proposals (CP) invites the astronomical community to propose for observing time on HST in a given cycle (nominally one year in duration). It summarizes the policies and procedures for proposing in that cycle of HST observing, including requests for funding research on archival HST data. A CP for a given cycle is issued approximately a year before the nominal start of the cycle.

- Phase I: Writing and submitting a proposal for HST observing time

  The CP describes in detail the policies and procedures for submitting a Phase I proposal for HST. Proposers should also consult all relevant technical documentation about the capabilities and sensitivities of the instrument(s) to be used in their programs and should discuss the requirements of their observing programs with appropriate Space Telescope Science Institute (STScI) experts. Contacts are provided via the STScI Help Desk at help@stsci.edu. To avoid duplication conflicts proposers also should consult up-to-date exposure ASCII catalogs, the Duplication Checking Web Form or the Duplication Check Screen in StarView.

- Phase II: Providing the details

  A Telescope Allocation Committee (TAC), organized by the STScI, reviews and evaluates the submitted Phase I proposals. The TAC recommends a list of programs to the STScI Director for preliminary approval and implementation. Upon final approval by the Director, a successful proposal enters into the Phase II stage of proposal preparation, during which proposers must provide the details required by the ground system to schedule HST and obtain their observations.

Most HST observations have proprietary periods of one year, during which the data are only accessible to the proposers. More details on HST proprietary rights are available.

GO/GTO Support

Hubble Space Telescope (HST) archive support for general observers (GOs) and guaranteed time observers (GTOs) include:

- **Reference files.** For several HST instruments improved calibrations, as compared to the calibrated files available in the archive, are possible with newer calibration files. These files can be retrieved for a given dataset using this interface. Note that with the release of On-The-Fly Reprocessing (OTFR), archive users can obtain WFPC2, NICMOS, and STIS data that are processed with the latest calibration files, software, and data parameters. The OTFR is performed whenever a request is received for archived data.

- **PDF paper products.** Using this interface users can search for, and display, the HST observation summaries now offered in Portable Document Format (PDF). These documents, formerly available only in hardcopy and referred to as the HST "paper products", provide a quick first look at the data. The PDF documents are password protected and users will need their archive name and password to access them. More information on paper products is available. Note: The automatic generation of PDF observation summaries was terminated on March 19th, 2002. The current interface will allow users to view the remaining online observation summaries dating roughly from March 19th, 2002 back to June, 2001.

- **Proprietary rights.** Most GO and GTO observations have proprietary periods of one year, during which the data are only accessible to the proposers. More details on HST proprietary rights are available.

MAST Prepared Science Products

The following is a listing of sites of highly processed datasets from missions supported by MAST. These are datasets consisting of atlases, images, and/or the data themselves which have been placed on the web either as final data products or as appendices referenced in recent published papers. These data are in the public domain and/or will soon be published. The datasets are organized by type of observation (survey, individual objects, time series) and will include a growing number of catalogs with links to the data and in some cases spectra and/or images.

Deep Sky Surveys

- Hubble Deep Field
- Hubble Deep Field South
- Medium Deep Survey

Wide Field Survey Catalogs

- Magellanic Clouds Planetary Nebulae (HST)
- SDSS Quasar Catalog

Spectral Atlases: multi-object samples

- Ultraviolet Spectral Atlas of Standard Stars (IUE)
- Library of Copernicus Atlases of Selected Stars
- Far-Ultraviolet Spectral Atlas of Stars (EUVE)
- Library of IUE NEWSIPS SWP Echelle Spectra for White Dwarfs
- FOS Composite Quasar Spectrum (FOS)

Spectral Atlases: individual objects

- High S/N GHRS LSA G160M Observations of 10 Lacertae (HST)
- High S/N GHRS SSA Echelle Observations of chi Lupi (HST)
- High S/N GHRS SSA Observations of Chromospheric lines in Procyon (HST)
- High S/N GHRS LSA G270M Observations of alpha Ori (HST)

Time-Dependent Spectra

- Grayscale of Time Variations of gamma Cas near SiIV Doublet (HST)

Guidelines for authors of new prepared science products

For further information see: VizieR astronomical catalogs

HST Archive Documentation

The HST Archive Manual

Provides extensive information on how to access the HST and Multimission archives via two user interfaces, StarView and the World Wide Web. Gives advice on search strategies; higher level functions of StarView; descriptions of StarView screens and the HST catalog; nomenclature convention for HST data.

Version 7.0 of the Archive Manual was released in June 1999.

PDF version (3.9 Mb),

On-line version

Postscript version (gzipped) (2.1 Mb).

Users will find the PDF version more flexible and quicker to use. Loading of some chapters with the on-line version might take some time.

The HST Data Handbook

The comprehensive guide to calibrating, reducing, and analyzing HST data.

Archive Newsletters

The electronic newsletters provide information about the various archives supported by the Multi-mission Archive at STScI (MAST), including HST

Old HST Archive Newsletters [incomplete]:

Publication of HST Archival Research Results

The results of investigations with HST archive data are generally published in the scientific literature. All publications based on these data should carry the following footnote:

"Based on observations made with the NASA/ESA Hubble Space Telescope, obtained from the data archive at the Space Telescope Science Institute. STScI is operated by the Association of Universities for Research in Astronomy, Inc. under NASA contract NAS 5-26555."

If the archival research was supported by a grant from STScI, the publication should also carry the following acknowledgment at the end of the text:

"Support for this work was provided by NASA through grant number ________ from the Space Telescope Science Institute, which is operated by AURA, Inc., under NASA contract NAS 5-26555."

Please send one preprint or reprint of each refereed publication based on HST archival research to the following address:

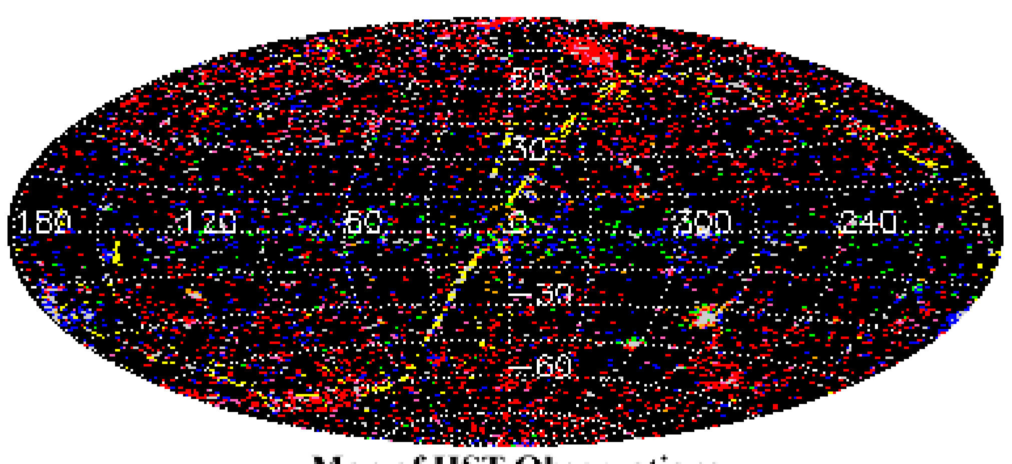
Hubble Space Telescope (HST) is an orbiting astronomical observatory operating from the near-infrared into the ultraviolet. Launched in 1990 and scheduled to operate through 2010, HST carries and has carried a wide variety of instruments producing imaging, spectrographic, astrometric, and photometric data through both pointed and parallel observing programs. MAST is the primary archive and distribution center for HST data, distributing science, calibration, and engineering data to HST users and the astronomical community at large. Over 100 000 observations of more than 20 000 targets are available for retrieval from the Archive.



Map of HST Observations

FUSE Abstract Search Help

This page describes how to use the *new* FUSE Abstracts Search form.

You can use the FUSE Abstracts Search to find FUSE observing program abstracts containing specified words or phrases. All FUSE program abstracts matching your search expression will be displayed. (Currently, all we have are the abstracts. Other information, such as the title, investigator, etc. will be added soon.) The characters in the abstracts that matched your search expression will be rendered in **red boldface** to make it easier to see why an abstract matched.

The expression syntax is similar to that used in an AltaVista simple search. Expressions consist of words or phrases (quoted strings) separated by whitespace. **The search is insensitive to case.** An abstract will match if it contains any of the words or phrases in the expression, unless the word or phrase is preceeded by a `+` or a `-` sign. Prefix a word or phrase with a `+` when the word or phrase is required to be present in the abstract. Prefix a word or phrase with a `-` to exclude abstracts containing the word or phrase.

(Please note that some searches, especially those involving complex expressions or matching a large number of abstracts, may take a minute or two to complete. Searches matching a large number of abstracts may also generate a very large results page.)

Here are some examples of how to use the syntax (remember that case is ignored).

Expression	means
`macho`	Finds every abstract containing *MACHO* (or *Macho*).
`macho microlens`	Finds every abstract containing either *MACHO* or *microlens*.
`"BL Lac"`	Finds every abstract containing *BL Lac*. Note that this expression is enclosed in quotes; otherwise, the expression would also have matched words like *capable* and *loblolly*, which is probably not what you wanted.
`+iue galax`	Finds every abstract containing *IUE* which may or may not contain *galax*.
`+iue +galax`	Finds every abstract containing both the strings *IUE* and *galax*.
`+iue +"BL Lac"`	Finds every abstract containing both the strings *IUE* and *BL Lac*.
`+euve -maneuver`	Finds every abstract containing *euve*, but *not* containing the word *maneuver*. (Note that the string *euve* is contained in the word *maneuver*.)
`xray x-ray "x ray"`	Finds abstracts containing any of *xray*, *x-ray*, or *x ray*. Note again that `"x ray"` is enclosed in quotes.

Future enhancements will include searching other information besides the abstract and adding query options, like case-sensitivity and scoring. (I'm trying not to clutter the interface too much though.)

Getting Started

Launched on June 24, 1999, the Far Ultraviolet Spectroscopic Explorer (FUSE) is a young high-dispersion spectroscopic mission. The instrument is optimized for the wavelength region 905-1185 Å and is particularly suitable for studies of interstellar atomic and molecular lines, heavy hydrogen abundances, the OVI resonance lines in hot stars, and the redshifted 584Å ("helium H-alpha") line of neutral helium in distant galaxies.

Unlike most astronomical space platforms, FUSE consists of four coaligned telescopes, each of which brings light to its own spectroscopic optical elements and are focused on one of two detectors. This segmented instrumental configuration serves to increase the telescope's effective aperture at low cost and to optimize detecting efficiency in different wavelength regions. Its capabilities make FUSE a natural follow-on mission to the earlier Copernicus, IUE, HUT, EUVE platforms.

A user can request FUSE data by going to the FUSE search page and selecting "Science Data Search." If you are not yet registered with an FUSE (HST) user account you must first do so to get to the data retrieval page. Instructions for this step can be found in the how to retrieve FUSE data page. Because FUSE is a young mission, a requestor will typically see a large fraction of listed datasets to be coded in yellow. This means that they are still proprietary to the original proposer.

Before investigating data, the observer should be aware of several caveats which are unique to FUSE and can affect the spectral quality. In the future preview (quick-look) spectral images will be available in at least two different stages of pipeline reduction in order for an investigator to assess the quality and possible problems for a given exposure. The Observer's News page should also be consulted for recent changes in the status of FUSE instrument or pipeline processing of data or for answers to FAQs.

Search and Retrieval

FUSE data are contained can be found by using the main FUSE search form to request one or more observations from the data archive catalog. Most users request observations by observation, but for some applications it is desirable to request certain "exposures" within an observation, and the exposures search form provides this capability. This form may be accessed by clicking the link to it in the upper left corner of the main FUSE search form or from the gutter. Note that because FUSE is an active mission data are being put into the public access area continually. One can get a list of additions within the last several days by consulting the daily data reports

Once the user has found FUSE data he/she wants to retrieve, he/she may need to register for an archive account. If the user has already done this to obtain Hubble data, this step is unnecessary. Registration help is available, or users can access registration forms on line or contacting the HST Archive Hotseat. Before registering, users should read about our retrieval policies. Once users are registered, they will have an archive retrieval account with an associated username and password.

After searching the FUSE archive, the datasets of interest can be marked for retrieval with the `mark' button and then submitted for retrieval to DADS, the STScI Data Archiving and Distribution Service. f you have problems making the search query, consult the **search help** page. Different retrieval options are available, including ftp of the data to the user's home machine and transfer (for public data only) to the archive staging disk. DADS will send email when the request is completed.

Once the requested files are located, they are written to a data distribution disk area on the system, bundled into a tar or zip format file, and downloaded to the disk area specified by the user in the "save as.." pop-up window. The files are downloaded when the pop-up window disappears.

If you have problems retrieving your data, you can contact the help desk via the link at the bottom of this page.

Daily Data Reports

This area contains reports of recently archived and recently released FUSE data. The reports are updated automatically every morning at 5:00AM Eastern US time. All reports are sorted on program ID. more information.

A FUSE dataset is "released" when its proprietary period expires. The default proprietary period of FUSE data is six months from the time of ingest into MAST. Once the dataset is released, it may be retrieved from MAST without special authorization. Principal investigators and co-investigators may have their MAST archive accounts enabled to retrieve proprietary data from their observing programs. Contact archive@stsci.edu for more information.

The links labeled *gz* are the gzip-compressed versions of the reports. Most modern browsers are capable of handling compressed HTML on the fly, so these compressed versions may download significantly faster for you than the uncompressed versions, especially over a slow Internet connection.

Data released within the last 3 days (*gz*), 7 days (*gz*), 14 days (*gz*), or 28 days (*gz*)

Mission/category: ALL all Go

List all changes for FUSE

More MAST mission data now on-line
2002 February 27
All IUE, UIT, BEFS and VLA-FIRST data are now on-line on a RAID array. The response time for data downloads for these missions should improve significantly. Data for missions HUT, WUPPE, TUES, and Copernicus were already on-line. HST and FUSE data remain on DADS and response times for data download for these two missions are not affected. EUVE data are held at HEASARC and this data is also not affected.

Name Resolver Option Available in Cross Correlation search
2002 January 15
The cross correlation search option available from the top MAST page now allows a choice of NED or SIMBAD for resolving user-specified target names. (The previous version only used SIMBAD.)

New MAST/ADS Data Links
2002 January 11
The ADS data links to data archived winthin MAST have been revised. Now a link to a single MAST page is shown which displays all the known MAST references for a single bibcode. (See 1995ApJ...449..488R as an example.)

New Plotting Option Offered in MAST Scrapbook
2001 October 18
A new option for coplotting multiple spectra and adjusting plot scales is now available in the MAST scrapbook.

Data Characteristics Plots Updated
2001 June 13
The MAST Data Characteristics plots have been updated to include the FUSE, TUES, BEFS, and SDSS missions.

Target Search Error
2001 June 12
An error was discovered in the target search available from the main MAST page. Searches would fail for object names containing special characters (such as a "+" symbol as in BD +28 4211). The error was fixed on the above date.

Implementation of Redesigned MAST Web Site
2001 June 4
The MAST redesigned web site is now online. The new dynamically-generated pages feature a common page layout, options for site-wide index searches, mission-specific target name searches, easier site navigation, and a printer-friendly page display option.

FUSE Daily Data Reports
2000 November 20
We've added a set of pages showing recently archived and recently released FUSE data. These pages are automatically updated every day.

FUSE Search Pages Revised
2000 August 28
Minor changes were made to the science and exposures search and retrieval pages. Help files are also now available describing the column headings of the search results tables.

New FUSE Page
2000 August 21
The MAST FUSE page has been revised following the format used for the other MAST mission pages. An "all sky" plot was also added showing FUSE observations up through August 18th, 2000.

Cross Correlations with Sky2000 Catalog
2000 August 16
Cross correlations of MAST missions with the SKYMAP Sky2000 catalog (version 3) are now possible from the MAST Cross Correlation page.

New Copyright Notice
2000 May 12
STScI has adopted a new Copyright statement. Most, if not all, MAST web pages should now include a link to the new page.

FUSE
1999 June 24
FUSE is launched. FUSE data will be archived and available through MAST.

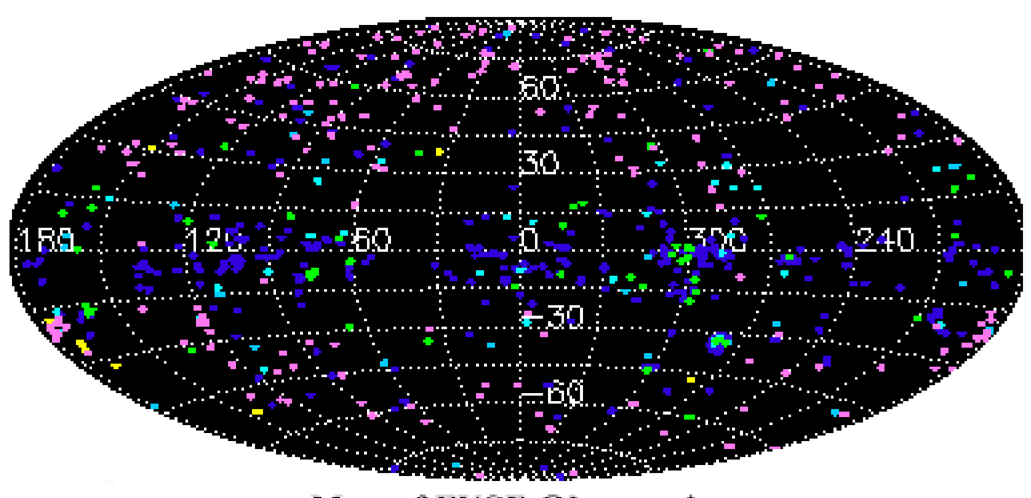
The Far Ultraviolet Spectroscopic Explorer (FUSE), launched on June 24, 1999, covers the 905-1187 Å spectral region and will obtain high resolution spectra of hot and cool stars, AGNs, supernova remnants, planetary nebulae, solar system objects as well as perform detailed studies of the interstellar medium. FUSE will be able to observe sources 10 000 times fainter than Copernicus, an early FUV mission, and has superior resolving power than the Hopkins Ultraviolet Telescope (HUT) and the Berkeley Spectrograph (BEFS) and the Tübingen Echelle Spectrograph (TUES) of the Orbiting Retrievable Far and Extreme Ultraviolet Spectrometers (ORFEUS). FUSE was planned for a 3 year lifetime with funding for an additional 2 years expected.

More information about the FUSE Guest Investigator program, including PI and Cycles 1 and 2 GI target lists, may be found at the FUSE Guest Investigator Program site at http://fusewww.gsfc.nasa.gov/.

Although FUSE data is maintained and archived within MAST, most of the documentation available from the MAST FUSE page is obtained from the Johns Hopkins FUSE website.



Map of FUSE Observations

Getting Started

The International Ultraviolet Explorer (IUE) satellite was a unique space observatory in that it was operated like a ground-based observatory. Astronomers came to the Telescope Operations Center and directed their observations while observatory staff members commanded the instrument and read down the data in real time. It was launched on January 26, 1978, and operated for nearly 19 years until September 30, 1996. The instrumentation included two spectrographs, one from 2000 to 3300 Å and the other from 1200 to 2000 Å, in both high (R ~ 10,000) and low (R ~ 300) resolution modes.

The archive of over 107,000 spectral images includes about 9200 individual objects, many of which were observed repeatedly for variability studies. All types of astronomical objects, from planets to galaxies, were observed by IUE but a major portion of the archive is devoted to stellar observations. The search form may be used to select data from the IUE catalog by object name, coordinates, observing mode, date of observation, etc. The data files of interest may then be marked and retrieved.

MAST holdings contain the fully reduced and calibrated spectra in two versions. The first version consists of the original processed data using the IUE Spectral Image Processing Software (IUESIPS). The data files are stored in VICAR header format and can be read and analyzed with the IUE Data Analysis Center (IUEDAC) software package written in IDL. The data were later reprocessed using new calibrations and improved processing techniques (NEWSIPS), producing a second version known as the IUE Final Archive. The NEWSIPS data files are stored in FITS format and may be read with a variety of FITS readers, including iuetools in IRAF and programs in the IUEDAC software package. The Final Archive data are the preferred version for most applications, but both versions are available.

Search and Retrieval

The IUE Archive is currently maintained at the Space Telescope Science Institute (STScI) as part of **MAST**, the Multi-mission Archive at STScI. The data are stored in gzipped compressed format on compact discs (CD's), and accessed through a CD jukebox. The IUE archive contains data processed from both the IUESIPS and NEWSIPS data processing systems. Primary access is via the web although alternatively, users may **download IUE files via ftp**. Additional data retrieval methods may be available in the near future.

Normally web users will search the IUE database for particular files using the **IUE search page**. The returned table of found entries will allow the user to mark the images to be downloaded. Alternatively, if the camera and image numbers are already known, they can be directly entered into the **IUE data retrieval** page. Your request for data begins a retrieval job. Several CD's may need to be accessed in order to obtain the files you have requested. Once the requested files are located, they are written to a data distribution disk area on the system, bundled into a tar or zip format file, and downloaded to the disk area specified by the user in the "save as.." pop-up window. The files are downloaded when the pop-up window disappears.

If you have problems reading the file formats, please check our **data retrieval help** page for suggested ways to read the downloaded compressed files.

If you have problems retrieving your data, please contact the ST Archive **help desk.**

IUE Retrieval Options

Image IDs

NEWSIPS Data:	**IUESIPS Data:**
MX (FA extracted spectra - mxlo,mxhi)	ME (SIPS - MELO,MEHI)
EXTRACT-FA (si,mx)	EXTRACT (SIPS - MELO,ELBL,MEHI)
ALL-FA (ri,li,si,mx)	ALL (SIPS - raw,mehi,melo,elbl)
SI (FA resampled spectra - silo,sihi)	ELBL (SIPS - Extracted line-by-line)
RI (FA raw image - rilo,rihi)	RAW (SIPS - Raw data file)
LI (FA linearized image - lilo,lihi)

Data Retrieval Help Page

To retrieve IUE data, mark the rows in the search results page of the desired exposures (or click on the "more retrieval options" page and enter camera and image numbers in the list under "image IDs"). Once the desired files are marked, several options are available for formatting and compressing the data. Generally, MAST files are most efficiently (and quickly) downloaded as a bundled tar or zip file. This means however, that the user is left with the task of extracting the files. The descriptions below list the programs available on different operating systems for reading the various file formats.

Clicking the "Download NEWSIPS MX Files as a .tar file" from the IUE search results page will download a tar file of NEWSIPS FITS files. Users desiring a zip file, or a gzipped tar file, should click the "More retrieval options" button **after** selecting the desired files from the search results list.

Other options available from this page include downloading NEWSIPS, IUESIPS-GO, or IUESIPS-RDAF format files, selecting various NEWSIPS or IUESIPS file types, or requesting files by entering the IUE camera names and image numbers. **Note the current retrieval options allow only one data type and one file format to be requested at a time and the two selected options must agree (e.g. don't select NEWSIPS files and an IUESIPS file type).** If both IUESIPS and NEWSIPS files are desired, two separate file downloads are required.

Data Type
Requests can be submitted for either IUESIPS or NEWSIPS files. NEWSIPS files are in FITS format while IUESIPS data is archived in IUE GO format and needs special software to be read. In general, NEWSIPS data is recommended for most users.

Conversion Options
IUESIPS data can be requested in either GO or RDAF formats. The default format is GO. IUE RDAF software uses RDAF format files, however the IDL program GOTORDAF can be used to convert GO format files to RDAF format (see also RDAFTOGO).

File Download Options The current IUE file download options include:

Data Format:

- NEWSIPS - FITS files produced by the IUE New Spectral Image Processing System,
- IUESIPS_GO - IUE GO format files produced by the original IUE Spectral Image Processing System,
- IUESIPS_RDAF - IUESIPS-processed files in RDAF-format.

Data Compression Options:

- .tar - uncompressed files bundled in a tar file. (Note, prior to 10/21/99, the individual files were also gzipped by default.)
- .tar.gz - files are bundled into a tar files which is then compressed using gzip.
- .zip - files are bundled (and compressed) into a zip file,

Download times can vary according to the number of CD's needed to be mounted in order to fulfill the data request. NEWSIPS MX files (i.e., mxlo or mxhi files) however are now online and can therefore be retrieved much faster. Users know when the request is completed when the browsers "Download window" disappears. Requests for a few files are normally completed in a couple of minutes.

It should be pointed out that the "time Left" gauge in the pop-up window will not accurately show the remaining download time. The file transfer speeds will eventually be displayed, but the download is basically not complete until the pop-up window disppears.

In addition to the requested files, users will also receive an ASCII text file called **filetypes.txt** which describes the various IUE data types, and, an ASCII text file called **status.txt** describing the status of the users data request. More information on status.txt is provided below.

UNIX

For unix users, the downloaded tar files can be extracted using the command:
$ tar xvf filename

Gzipped tar files can be read the same way, after first running the command:
$ gunzip filename

Requested ZIP files can be opened using unzip:
$ unzip filename

If FITS files were requested, the uncompressed files can be read with a standard FITS reader (although it must support binary table extensions). If IUESIPS GO format files were downloaded, they can either be read using custom software, or converted to rdaf format using the gotordaf routine from the IUEDAC IDL library. RDAF format files can also be requested directly from MAST.

VMS

Since gzipped, tar, and zip file formats are not as common on VMS systems, users may first need to download the software necessary to extract the downloaded files. GUNZIP, TAR2VMS, and UNZIP are all public domain software available from DECUS. To see if these programs are already available on your system, type:
$ show symbol tar2vms
$ show symbol gunzip
$ show symbol unzip
Depending on the format you select for downloading the files, if the program you want is undefined, (and assuming it doesn't exist under another name) they can be downloaded as follows:

Download the TAR2VMS executable by clicking on the appropriate OpenVMS system below:

- (VAX `tar2vms` executable) (15 blocks)
- (ALPHA `tar2vms` executable) (20 blocks)

Once you have downloaded the executable, type the following commands (note the first command defining tar2vms could be added to your login.com file):

VAX:

$ tar2vms :== $disk:[account]tar2vms.exe
$ tar2vms xvf iue.tar
or ALPHA:
$ tar2vms :== $disk:[account]tar2vms_alpha.exe
$ tar2vms xvf iue.tar

where "disk" and "account" are the names of the disk and directory where the executable resides.(Note the "$" in front of the disk name!) The file "iue.tar" listed above is an example of the file name downloaded from MAST. The actual name will depend on the file format requested.

The gunzip program (as well as unzip for ZIPed files) can be dowloaded directly from **Digital**. Be sure to select the appropriate executable for your system (i.e., *-vax for vaxes, *-axp for alphas). To install gunzip or unzip, follow the directions above for tar2vms. That is, define a symbol for the command name (with the "$" added to the file path) and then just type (for example):
$ unzip iue.zip   or
$ gunzip iue.tar.gz
(Note after downloading and unpacking RDAF format IUESIPS files, VMS users will need to convert their files with a program such as CON_RDAF (i.e., using the SPARC to VMS mode option).

The above commands will create a subdirectory called IUE containing all the requested files. NEWSIPS files will have names in the form swp12345.mxlo, while IUESIPS files will have names such as swp12345llg.dat & .lab, or swp12345.melol.

IUESIPS files can be requested from the "More Retrieval Options" page in either GO format, or RDAF format. After extracting, GO format files will have names such as swp12345.melol, while RDAF format files will have names such as swp12345llg.dat and swp12345llg.lab. The main differences between the 2 formats is that the RDAF format stores the VICAR label in a separate file from the data and, the data stored in the RDAF .dat files are assumed to be converted to a format compatible with the local operating system. Because of the latter difference, VMS users planning to use the IUERDAF IDL software should run the program con_rdaf on all rdaf-format files. (i.e., using the SPARC to VAX mode option). (Since the MAST archive is stored on a unix computer, no conversion is needed when the files are downloaded to unix or Macintosh computers.) Alternatively, users may request GO format files and convert them to RDAF format using the IUERDAF program GOTORDAF. For example, to convert the file described in the example above from GO to RDAF format, simply type (from IDL):
IDL> gotordaf,'swp07971.melol'
This will produce a standard .dat and .lab file in the format appropriate for the host computer. (The RDAF IDL routines can be downloaded from the **IUEDAC** web page.)

Windows

If you are using a PC running Win3.x, Win95, or WinNT, you can request the data in either tar or zip format and use the shareware program **WinZip** to both uncompress and extract the files. Extracting the tar or zip file from WinZip will create an IUE subdirectory containing the images requested. If you don't have WinZip, the programs **pkzip/pkunzip** should also work, but they have not been tested.

The tar.gz format can also be read on a pc, but in our experience with WinZip, the system renames the downloaded file to be iue_tar.gz (instead of the original iue.tar.gz), and therefore the file may need to be renamed to iue.tar to be recognized as a tar file after unzipping.

IUESIPS files can be requested from the "More Retrieval Options" page in either GO format, or RDAF format. After extracting, GO format files will have names such as swp12345.melol, while RDAF format files will have names such as swp12345llg.dat and swp12345llg.lab. The main differences between the 2 formats is that the RDAF format stores the VICAR label in a separate file from the data and, the data stored in the RDAF .dat files are assumed to be converted to a format compatible with the local operating system. Because of the latter difference, Window users planning to use the IUERDAF IDL software should run the program con_rdaf on all rdaf-format files. (i.e., using the SPARC to MIPSEL mode option). (Since the MAST archive is stored on a unix computer, no conversion is needed when the files are downloaded to unix or Macintosh computers.) Alternatively, users may request GO format files and convert them to RDAF format using the IUERDAF program GOTORDAF. For example, to convert the file described in the VMS example above from GO to RDAF format, simply type (from IDL):
IDL> gotordaf,'swp07971.melol'
This will produce a standard .dat and .lab file in the format appropriate for the host computer. (The RDAF IDL routines can be downloaded from the **IUEDAC** web page.)

Macintosh

Mac users can now use a free file-decompressor program called **MindExpander** from MindVision, to extract .zip and .gz files. Alternatively, the standard (but not free-ware) **Stuffit Deluxe** utility can also be used. Other utilities include: **UnZip**, **ZipIt**, and UnTar. Since most utilities only support zip or gz files, Mac users may want to request zip format rather than tar from the "more retrieval options" page. Tests run with Stuffit Deluxe however, showed that tar files can be read without any trouble.

IUE Data Types

The available IUE data types are displayed on the "More Retrieval Options" page and are described below. Normally users request the merged extracted spectral files (i.e., NEWSIPS MXLO or MXHI files, or IUESIPS MELO or MEHI files). Additional documentation is available on both the NEWSIPS and the (GO-format) IUESIPS data products.

NEWSIPS Files

- **MX** - The merged extracted spectral files containing the absolutely-calibrated fluxes, wavelengths, data quality flags, and sigmas (or noise estimate for MXHI files) in a FITS binary table extension. The high dispersion files are named MXHI and the low dispersion files are MXLO. Note that although low dispersion double aperture exposures are listed as two separate entries on the search results page, both spectra are contained in one MXLO file.
- **EXTRACT** - This group contains the MXLO, MXHI files described above, plus the resampled image files (SILO & SIHI) from which the fluxes were extracted. The SI files contain the photometrically-corrected and rotated image as a primary array, wavelength information in a binary table extension, and an image extension containing an array of data qualiy flags. These files are useful for identifying camera artifacts such as cosmic ray hits, etc.
- **All-FA** - All the archived NEWSIPS data products for a given observation can be requested by selecting this group. In addition to the files above, the RILO, RIHI raw image files (a 768x768 primary array image) and the LILO, LIHI linearized image files (a 768x768 primary array file with associated data quality flags as a 768x768 array image extension) will be downloaded.
- **SI** - Select this group if only the SILO, SIHI resampled image files are to be downloaded.
- **RI** - This group allows only the RILO, RIHI raw image files to be downloaded.
- **LI** - This group allows only the LILO, LIHI linearized image files to be downloaded.

IUESIPS Files

- **ME** - This group includes the merged extracted spectral files containing the absolutely-calibrated fluxes, wavelengths, and data quality flags in a project-defined data format based on VICAR. The high dispersion files are named MEHI and the low dispersion files are MELO.
- **EXTRACT** - This group contains the MELO, MEHI files described above, plus the low dispersion resampled line-by-line image (ELBL) files from which the fluxes were extracted (note no IUESIPS high dispersion resampled images were generated). The ELBL files contain the photometrically-corrected image data, wavelength information, and data qualiy flags. These files are particularly useful for identifying cosmic ray hits, reseau, microphonic noise, etc.
- **ALL** - All the IUESIPS archived data products for a given observation can be requested by selecting this group. In addition to the files above, the RAW image file (a 768x768 array) will be downloaded.
- **ELBL** - This group allows only the low dispersion resampled image (ELBL) files described above to be downloaded.
- **RAW** - This group allows only the RAW image files to be downloaded.

Status.txt File

The status.txt file is downloaded along with the users requested files to provide information on the users request. This file may be useful for explaining why an expected file was not received. The following information is currently included in these files:

- **Observations requested** - The number of camera name/image sequence number entries specified by the user.
- **Requested data types** - A list of the IUE data types (e.g., melo, sihi, etc.) to be retrieved from the MAST archive as specified by the user in the data type menus on the "more retrieval options" page, or as specified on the search results page if downloading MX files was requested,
- **Compression type** - The method used to compress/bundle the requested files. The possible values are:
  - tar - files will be bundled as a .tar file.
  - zip - Files bundled and compressed as a zip file with no further compression applied to individual files.
  - tar.gz - Files bundled as a gzipped tar file
- **Data format** - Describes whether NEWSIPS, IUESIPS-GO, or IUESIPS-RDAF format files were requested,
- **File list** - The list of downloaded files showing the (uncompressed) file name and the uncompressed file size in kilobytes. A message will appear next to any entries either "not found in the database" or, more rarely, "found in the database but not located on the jukebox". (Users should report any missing files to archive@stsci.edu.)
- **Total number of found files** - The total number of files found in the database that were requested by the user. Note that it's possible for files to be listed in the database but still not available from the CD jukebox. These cases should be reported to archive@stsci.edu.
- **Total file size** - The total amount of disk space (in kilobytes) required to uncompress the requested files. Note that RDAF format IUESIPS file sizes are approximate.

Retrieving IUE Data via FTP

The IUE archive consists of raw and processed data produced by both the IUESIPS and NEWSIPS data processing systems, and is accessible through MAST, the Multi-mission Archive at STScI. The data sets are stored in gzipped compressed format on compact discs (CD's), and accessed through a CD jukebox. Although most users access the archive via the IUE search page using a web browser, FTP access is also possible using either a web browser (i.e., ftp://archive.stsci.edu/pub/iue/data/), or, as explained below, using anonymous ftp from an ordinary terminal with network access.

Users should be cautioned that FTP access is currently restricted in the following ways:

1. the user must already know the camera name, image sequence number, and the data type of the file(s) to be downloaded,
2. no files conversions are currently available via ftp, so returned files are sent individually, in gzipped compressed mode.

In general, IUE data is accessed via symbolic links in subdirectories under /pub/iue/data. The directories are organized by camera name and image sequence number. A separate directory exists for each camera (i.e., lwp,lwr,swp,swr) and below each of these directories is a separate directory for each 1000 image numbers. These directories are named according to the starting image number in each group (i.e., 1000, 2000, 3000, ...). As an example, a typical interactive ftp session to retrieve files lwp21500.mxlo.gz and lwp21500.silo.gz would be:

ftp archive.stsci.edu
anonymous
username@univ.edu
binary
cd /pub/iue/data/lwp/21000
get lwp21500.mxlo.gz
get lwp21500.silo.gz

To simplify access, two shell scripts and a vms command file have been written which require the user to specify only the file name and the desired data type. The programs determine the file path based on the input image name. In addition to downloading the data, the VMS command file also renames the files. Because VMS file names are not allowed to have two decimal points, a file named lwp21500.mxlo.gz would normally be downloaded as lwp21500.mxlo$5Ngz. (at least this is what we've found using Multinet ftp). The command file getiue.com renames these files to lwp21500_mxlo.gz, uncompresses them (requires gunzip) and them renames them to be (for example) lwp21500.mxlo. The shell scripts **iuemulti**, **getiue** and the VMS command file **getiue.com** are all available via ftp on archive.stsci.edu in /pub/iue/software/data_retrieval.

If you have problems reading the file formats, please check our **data retrieval help** page for suggested ways to read the downloaded compressed files.

If you have problems retrieving your data or wish to donate your own shell scripts or programs for accessing MAST data, please contact the ST Archive **help desk.**

What's New for IUE during last year

More MAST mission data now on-line
2002 February 27
All IUE, UIT, BEFS and VLA-FIRST data are now on-line on a RAID array. The response time for data downloads for these missions should improve significantly. Data for missions HUT, WUPPE, TUES, and Copernicus were already on-line. HST and FUSE data remain on DADS and response times for data download for these two missions are not affected. EUVE data are held at HEASARC and this data is also not affected.

Name Resolver Option Available in Cross Correlation search
2002 January 15
The cross correlation search option available from the top MAST page now allows a choice of NED or SIMBAD for resolving user-specified target names. (The previous version only used SIMBAD.)

New MAST/ADS Data Links
2002 January 11
The ADS data links to data archived winthin MAST have been revised. Now a link to a single MAST page is shown which displays all the known MAST references for a single bibcode. (See 1995ApJ...449..488R as an example.)

Coplotting Option now available for IUE Spectra
2001 December 10
A new option is available on the search results page of the IUE search script which allows users to coplot up to 15 selected IUE spectra and interactively rescale the resulting plot.

New Plotting Option Offered in MAST Scrapbook
2001 October 18
A new option for coplotting multiple spectra and adjusting plot scales is now available in the MAST scrapbook.

Data Characteristics Plots Updated
2001 June 13
The MAST Data Characteristics plots have been updated to include the FUSE, TUES, BEFS, and SDSS missions.

Target Search Error
2001 June 12
An error was discovered in the target search available from the main MAST page. Searches would fail for object names containing special characters (such as a "+" symbol as in BD +28 4211). The error was fixed on the above date.

Implementation of Redesigned MAST Web Site
2001 June 4
The MAST redesigned web site is now online. The new dynamically-generated pages feature a common page layout, options for site-wide index searches, mission-specific target name searches, easier site navigation, and a printer-friendly page display option.

Frequently Asked Questions

Data Requests

- Why do I get 2 IUESIPS MELO files for some low dispersion images but only 1 NEWSIPS MXLO file?
- Can I request IUE data in ASCII format?
- Why are some IUE NEWSIPS data not available? The IUESIPS version is available from the archive.

Reading Files

- How do I read NEWSIPS files into IRAF?
- How do I read NEWSIPS files into IDL?
- Why are my RDAF-format IUESIPS files unreadable after I transferred them from NDADS to my unix workstation?
- Can I use SAOimage to look at NEWSIPS files?

NEWSIPS Processing

- What is the wavelength scale used for NEWSIPS? Is it heliocentric?
- I have a NEWSIPS image which may not have been processed correctly (wrong dispersion, wrong exposure time). How can I get a correct version?
- The wavelengths for the Mg II h and k lines are very different, by almost an Angstrom, between my IUESIPS and NEWSIPS high-dispersion data. Is this an error?
- The wavelengths for my high-resolution NEWSIPS spectra seem to be off by almost an Angstrom. What happened?

ASCII Logs

- Are there ASCII files containing the IUE Merged Log?

Data Analysis

- When analyzing data, which of the data quality flags should I use to throw out pixels?
- When coadding like spectra, should I weight the constituent spectra by exposure time or the square root of exposure time?
- Whew! Is there a simpler way of estimating noise?

Data Requests

- ***Why do I get 2 IUESIPS MELO files for some low dispersion images but only 1 NEWSIPS MXLO file?***
  In IUESIPS, the extracted data for large and small aperture data from a given image were archived as two separate files (e.g. MELO1 and MELO2). In NEWSIPS, the extracted data for both apertures were archived in the same FITS file (e.g. MXLO).

- ***Can I request IUE data in ASCII format?***
  ASCII versions of the mxlo and mxhi files are available. From the search results page click on the object name to display the preview image. The ASCII versions can be downloaded by clicking on the line "Download a gzipped ASCII file of the large/small aperture preview spectrum." This line is found at the bottom of the preview page. If the image contains an exposure for both apertures, there will be a line and file for each aperture.

- ***Why are some IUE NEWSIPS data not available? The IUESIPS version is available from the archive.***
  There are various reasons why certain images may not be available. Some images are have problems that can't be handled by the NEWSIPS software but are glossed over by IUESIPS. Some images were misplaced during the processing and archiving process; we are chasing them down now. If you are interested in a particular image that doesn't seem to be available, please contact us and we will find out and make it available to you if possible.

Reading Files

- ***How do I read NEWSIPS files into IRAF?***
  The **iuetools** package will allow users to read NEWSIPS files. Currently the package requires IRAF (V2.11 or later), TABLES (V2.0 or later) and STSDAS (V2.0 or later). Here is more information.

- ***How do I read NEWSIPS files into IDL?***
  IDL programs are available to read in the NEWSIPS files. Use READMX to read either MXLO or MXHI files, and READSI to read either SILO or SIHI files. See the IUEDAC User's Guide for more information.

- ***Why are my RDAF-format IUESIPS files unreadable after I transferred them from NDADS to my unix workstation?***
  RDAF format files from NSSDC use the VAX VMS floating point data format and must be converted to IEEE format before being copied to a unix workstation. See our helpful hints about file copying from NDADS for more information. **(Note however that IUE files are no longer available from NDADS.)**

- ***Can I use SAOimage to look at NEWSIPS files?***
  Yes, it will handle the RI, LI, and SI files but not the VD and MX files. Use the options -fits to tell SAOimage that the files are FITS and -upperleft to display the images in the usual orientation, e.g. saoimage -fits -upperleft SWP12345.RILO. Adding the options -min and -max to scale the dynamic range of the grayscale display is also a good idea.

NEWSIPS Processing

- ***What is the wavelength scale used for NEWSIPS? Is it heliocentric?***
  Yes, the wavelengths have been corrected for both the Earth's motion around the Sun and the IUE spacecraft's motion around the Earth, computed as of the start of the exposure. A more up-to-date platinum-neon line library was used to create the wavelength calibration, resulting in some small systematic changes in the wavelength scale compared to IUESIPS. Some other small differences compared to IUESIPS are described in the NEWSIPS Manual Appendix III.

- ***I have a NEWSIPS image which may not have been processed correctly (wrong dispersion, wrong exposure time). How can I get a correct version?***
  Please let us know; we certainly would like to correct any errors. We have a limited capability to reprocess images through NEWSIPS if there was an error in the processing. Send email to archive@stsci.edu.

- ***The wavelengths for the Mg II h and k lines are very different, by almost an Angstrom, between my IUESIPS and NEWSIPS high-dispersion data. Is this an error?***
  The IUESIPS data follows the old convention of giving wavelengths in air for wavelengths greater than 2000 Å and in vacuum for wavelengths shorter than 2000 Å. The NEWSIPS data follow the new convention, also used by HST, of giving all

ultraviolet wavelengths in vacuum. The difference is pretty large. For instance, Mg II h is 2802.695 in air but 2803.52 in vacuum, Mg II k is 2795.53 in air but 2796.35 in vacuum, and Mg I is 2851.65 in air but 2852.49 in vacuum.

- ***The wavelengths for my high-resolution NEWSIPS spectra seem to be off by almost an Ansgtrom. What happened?***
  The NEWSIPS data follow the new convention of using ultraviolet wavelengths in vacuum. Most IUE data users are accustomed to using wavelengths in air for wavelengths longward of 2000 Å, i.e. all LWP and LWR data. (See also the answer to question about Mg II line wavelengths above.)

ASCII Logs

- ***Are there ASCII files containing the IUE Merged Log?***
  Yes, there are ASCII files with the IUE Merged Observing log. There are several subsets of the observing log available also.

Data Analysis

- ***When analyzing data, which of the data quality flags should I use to throw out pixels?***
  Almost certainly all of the nonzero flags. One can imagine situations (the only spectrum in the archives of your source) where you would want to "look" at a spectral feature which was uncalibrated, on the edge of the camera field, or whose fluxes were extrapolated beyond the highest ITF-calibration level - but even in this regime one would probably not want to try to conduct a quantitative analysis of the feature.

  Users should also be aware that no attempt was made in NEWSIPS to eliminate cosmic rays from the high-dispersion images, and the attempts made for low dispersion probably err on the conservative side. The reason for this was a concern that a provision for cosmic rays would lead NEWSIPS inadvertently to remove actual emission lines. Users should especially be cautious about the influence of oblique, diffuse cosmic rays, which can subtlely affect the background surface by 150 pixels or more from the centroid of the "hit" region and be responsible for less than optimal fits to the background surface. We suggest that the SIHI or SILO images be first visually screened before the extracted spectra are analyzed.

- ***When coadding like spectra, should I weight the constituent spectra by exposure time or the square root of exposure time?***
  Probably neither. An analysis of the noise properties of the IUE cameras for IUESIPS (e.g. as given by Ayres, PASP, 102, 1420, 1990 and PASP, 105, 538, 1993), but probably also applicable to NEWSIPS, suggests that the signal to noise gain is an increasing function of exposure time, but which is slower than either the limits of Exp_time or sqrt(Exp_time). Of course, the actual situation is even more complicated. For example, for integration longer than the "optimal" exposure time, illuminated pixels saturate and are useless. In this regime the quality of the data quickly *degrades*; saturated pixels can never be used for any purpose.

  For the coaddition of data, we recommend weighting individual spectra by reciprocal of the means of their noise fluctuations. (But in computing such a mean consider only those pixels with zero-value quality flags!) The "sigma" vector is computed by NEWSIPS as an estimate of these fluctuations as a by-product of the flux extraction process. For the extracted MXHI data the estimate for each wavelength pixel is based on predicted fluctuations of extraction slit pixels from the noise model for the same region of the camera. The units of the sigma vector in high dispersion are in "FNs" (Flux Numbers), the same as the *net flux* vector. For MXLO data the sigma vector is derived from the noise model, but it depends also upon the relative illuminations of pixels along the extraction slit. In this case the result is also scaled to units of *absolute flux*.

- ***Whew! Is there a simpler way of estimating noise?***
  Yes. The time-honored way is to find a stretch of continuum in the extracted spectra which contains no spectral features and is free of pixels of with negative data-quality flag values and then compute the rms formally from its noise fluctuations.

  Since "clean" continuum is not always easy to find, let's consider an empirical procedure which works well even for a spectrum containing features. As long as the flux errors are primarily gaussian-distributed, we can make use of the fact that randomly drawn samples will differ from one another, on average, by exactly one standard deviation. In the computing language IDL, an estimate of the rms may be computed conveniently by a few steps. Defining "*f*" as a spectral flux array taken from pixels near the blaze maximum (so the noise will be approximately uniform along the spectrum) and containing only zero-valued quality flags, we compute the mean point to point fluctuation of two pixels separated by a short distance *n*:

  The distribution of noise fluctuations among these pixels can be obtained from the computation:

  rmsdist = abs(*f* - shift(*f* , *n*)) .

  The median of this distribution is computed by sorting the distribution *rmsdist* and finding the middle element of the sorted *rmsdist* array, which by definition is half the number of elements in the distribution. Thus:

  ntot = n_elements(*rmsdist*), so *ntot2* , = *ntot*/2 ,

  Now we compute the sorted index distribution and take the value of *rmsdist* we need:

  isort = sort(*rmsdist*) ,

  medrms = *rmsdist*(isort(*ntot2*)) . *medrms* is the our noise estimate using the median average.

  The *mean* of the distribution can likewise easily be determined from:

  meanrms = total(*rmsdist*)/*ntot* .

  This value will be biased on the high side if there are outlying fluctuations in the spectrum. In practice the pixel separation distance *n* should be at least a spectral resolution element (3 or more).

The ***International Ultraviolet Explorer (IUE)*** performed spectrophotometry at high (0.1-0.3 Å) and low (6-7 Å) resolution between 1150 Å and 3200 Å. The data cover a dynamic range of approximately 17 astronomical magnitudes: -2 to 10 for high dispersion; -2 and 14.9 for low dispersion. Over 104,000 ultraviolet spectra were obtained with IUE between January 26, 1978, and September 30, 1996.

Getting Started

1. Introduction

The Extreme Ultraviolet Explorer (EUVE) was the first satellite entirely dedicated to the Extreme Ultraviolet (EUV) band of the spectrum (70 -760 Å). Launched June 7, 1992, EUVE conducted an all-sky survey that detected over 900 objects. The 6 month survey portion of the mission was followed by 8 years of pointed spectroscopic observations of over 350 objects. The EUVE instrumentation included the Deep Survey (DS) imager and 3 spectrometers. One-half of the light falling in the telescope was focused on the DS and the remaining half was intercepted by one the the spectrometers. The short wavelength spectrometer covered 70-190 Å, the medium wavelength spectrometer covered 140-380 Å, and the long wavelength spectrometer covered 280-760 Å. The resolving power was 260 in each spectrometer. The data from the 3 all-sky survey telescopes ("scanners") is not archived here.

The available data products for the EUVE spectrometers and Deep Survey instruments are stored in two different formats: 1) Binary FITS tables that include time-tagged events for temporal analysis (e.g. light-curves) and 2) 2-D FITS images of the DS and spectrometers. All 4 instruments are stored in a single FITS file with 4 extensions. The reductions that produced the 2-D images are expected to fill the needs of most users, but these can be re-extracted from the FITS tables. EUVE data resides at HEASARC, but are also available through MAST.

Search and Retrieval

EUVE data reside at HEASARC but may be accessed electronically through either MAST or HEASARC retrieval sites. The MAST **EUVE search form** has the same layout and similar query parameters as search forms of other MAST missions. Submission of this form initiates a a query to the HEASARC "W3browse" master catalog of EUVE observations (EUVEMASTER), which includes data taken from any of the Short Wavelength, Medium Wavelength, and Long Wavelength (SW, MW, LW) cameras or all sky Deep Survey. EUVE operated optimally with one or more of its cameras turned off at any one time. Data from all operational cameras during the observation are stored in multiple extensions of a common FITS file.

Once the requested files are located, they are written to a data distribution disk area on the system, bundled into a tar or zip format file, and downloaded to the disk area specified by the user in the "save as.." pop-up window. The files are downloaded when the pop-up window disappears.

If you have problems making the search query, consult the **search help** page. Once the data are downloaded one can go to the **reading EUVE data in IRAF** page to extract data and work with spectra or light curve. Historically, IRAF is the programming language of choice for the *reduction* of EUVE data from their native files. This is because special tasks were written in that environment to extract time-tagged photon events from background noise on the detector surface. IDL affectionados are encouraged to extract their data in IRAF first and proceed with their favorite IDL routines.

If you have problems retrieving your data, you can contact the help desk via the link at the bottom of this page.

What's New for EUVE during last year

More MAST mission data now on-line
2002 February 27

All IUE, UIT, BEFS and VLA-FIRST data are now on-line on a RAID array. The response time for data downloads for these missions should improve significantly. Data for missions HUT, WUPPE, TUES, and Copernicus were already on-line. HST and FUSE data remain on DADS and response times for data download for these two missions are not affected. EUVE data are held at HEASARC and this data is also not affected.

Name Resolver Option Available in Cross Correlation search
2002 January 15

The cross correlation search option available from the top MAST page now allows a choice of NED or SIMBAD for resolving user-specified target names. (The previous version only used SIMBAD.)

New MAST/ADS Data Links
2002 January 11

The ADS data links to data archived winthin MAST have been revised. Now a link to a single MAST page is shown which displays all the known MAST references for a single bibcode. (See 1995ApJ...449..488R as an example.)

EUVE Previews Updated
2001 October 24

Preview files were made available for the last 83 EUVE observations obtained in 2000 and 2001.

New Plotting Option Offered in MAST Scrapbook
2001 October 18

A new option for coplotting multiple spectra and adjusting plot scales is now available in the MAST scrapbook.

Data Characteristics Plots Updated
2001 June 13

The MAST Data Characteristics plots have been updated to include the FUSE, TUES, BEFS, and SDSS missions.

Target Search Error
2001 June 12

An error was discovered in the target search available from the main MAST page. Searches would fail for object names containing special characters (such as a "+" symbol as in BD +28 4211). The error was fixed on the above date.

Implementation of Redesigned MAST Web Site
2001 June 4

The MAST redesigned web site is now online. The new dynamically-generated pages feature a common page layout, options for site-wide index searches, mission-specific target name searches, easier site navigation, and a printer-friendly page display option.

Frequently Asked Questions

Data Requests

Instruments

Archive Data

Data Requests

- ***Where do I get EUVE archival data?***
  As of Nov 1997, the EUVE project in Berkeley is no longer delivering EUVE archival data. Events and image datasets, which may be reduced to create spectra and light-curves are available from this web site: click here to search the EUVE archive.

- ***How do I get multiple EUVE datasets?***
  If you are requesting multiple EUVE datasets, for now (since the data resides at HEASARC) you have to click on each data set or go to their ftp site. We will have a batch option in the future.

Instruments

- ***What are the wavelength ranges of the EUVE instruments?***

```
Spectrometer   Range (Å)     Resolution (Å)
   SW           70-190           0.5
   MW          140-380           1.0
   LW          280-760           2.0

Imagers:       10% Filter Bandpasses (Å)
DS Lexan              67-178
DS Al/C              157-364
ScA/B Lexan           58-174
ScA/B Al/Ti/C        156-234
ScC Ti/Sb/Al         345-605
ScC Sn/SiO           500-740
```

- ***What are the common EUVE spectral features?***
  The EUVE spectrometers have some common background features caused by airglow and scattering in the upper atmosphere.

  SW- The short-wavelength spectrometer can have a bright rim at shortest wavelengths (left) caused by scattered Lyman alpha.

  MW- The medium-wavelength spectrometer has a broad feature at 304 Å from geocoronal helium.

  LW- The long-wavelength spectrometer has a broad feature at 584 Å from geocoronal helium, which includes the 304 Å line in second order.

- ***What about the Deep Survey Deadspot?***
  There is a region of low gain (the "dead-spot") near the center of the Deep Survey Lexan/B band caused by the Feb 1993 observation of HZ 43. The region is about 2 arcmin in diameter and is described in detail in the EUVE technical memo.

- ***What about the Deep Survey's short wavelength response?***
  The short wavelength response of the DS has been investigated to explain large count rates observed from high column sources, like Sco X-1 and has often been termed "X-ray leak". The latest ideas have been summarized in John Vallerga's Memo.

Archive Data

- ***How do I get started with the EUVE permanent archive data?***
  Once you have obtained events and/or fits images from http://archive.stsci.edu/cgi-bin/euve, here are the 3 steps to read them:

  1) gunzip the files.

  2) read fits files with *strfits* (in *stsdas.fitsio*) (step no longer needed with IRAF 2.11, which allows you to read the fits files with out converting them. And *cep* will run on fits files).

  3) the img file will produce ds,sw,mw,and lw images + good times tables [you can go onto spectral extraction from these or continue and reduce the events files.]

  4) the evt file will produce the equivalent of the old format data (like table0 and so on) tables produced will have the following names: adcnts.tab lw_events.tab orientation.tab sw_events.tab ds_events.tab mw_events.tab quadrant.tab valid_times.tab)

  5) run *cep* to produce qpoe files using the appropriate script in archpipe (in egodata1.16) {Note: Only use "Rebuild DS SourceCentered Archive QPOE" for moving targets}

  6) use qpoe file as before

  Please also see the Permanent Archive Guide EUVE Permanent Archive Data Products Guide

- ***How do I extract an EUVE Spectrum?***
  In IRAF, use the EUV task *euvextract* on the two dimensional image file (which you get get from the source_date_img.fits file). See also: quick help on Spectral extraction?

- ***I run euvextract and get an error: 'dispaxis not found'.***
  You are missing DISPAXIS header line. This card was omitted from the EUVE archival format because it is specific to reduction of spectra under IRAF and, unlike the old GO products, the archival data format is not IRAF-specific.

  You can add the DISPAXIS card to an image with the standard IRAF task *hedit* . It will need to have the value '1', meaning the spectra run along the x-axis, as long as you haven't rotated the images.

- ***How do I make a Deep Survey Light-curve?***
  Quick Help on making a DS Light-curve

Instrumentation and Operations

The Extreme Ultraviolet Explorer (EUVE) conducted an all-sky survey for the first 6 months of its mission (July 1992 to January 93). Operations after the all-sky survey turned to pointed Guest Observer (GO) observations, mainly with the Deep Survey/Spectrometer instruments, although there were a few pointed observations of the all-sky survey telescopes of comets and low-column directions. EUVE ceased operations on January 31, 2001.

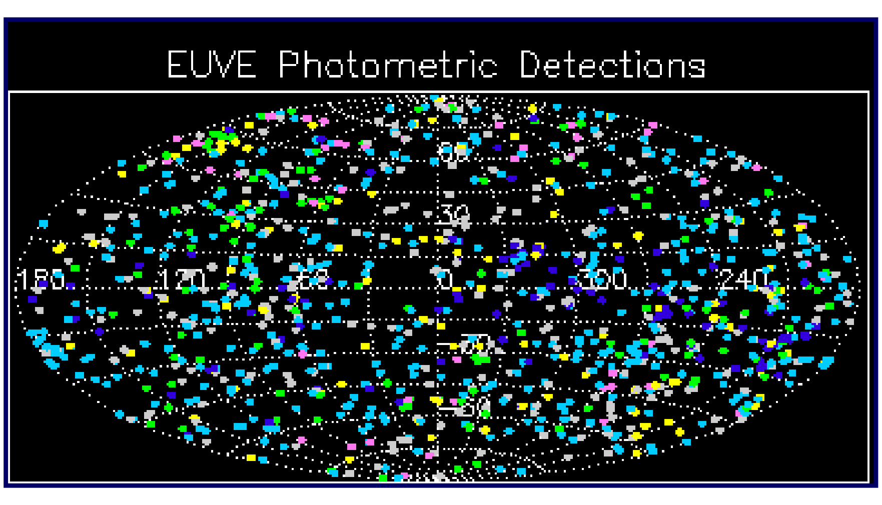
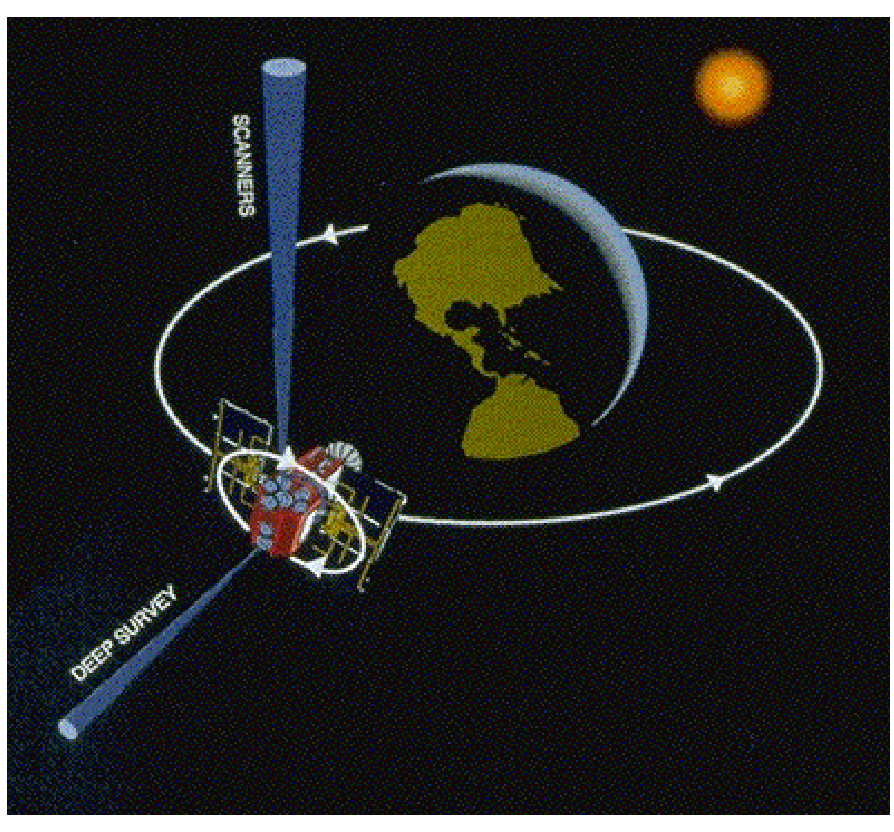
EUVE All Sky Survey

The survey phase of the mission started on 24 July 1992 and concluded on 21 January 1993. There were monthly calibration pointings conducted during this phase, and so the initial survey data included gaps in the sky coverage. Short periods of gap-filling were carried out during the first six months of the GO program. The completed survey data set covers approximately 97% of the sky with exposures ranging from a few hundred seconds at the ecliptic to 20 kiloseconds at the poles.

Two different kinds of sky surveys were simultaneously conducted. The EUVE's three scanning telescopes systematically measured the positions and intensities of sources across the entire sky, while the deep survey telescope mapped faint sources along a narrow band on the Ecliptic. The survey detected 734 objects. We show an aitoff projection of EUVE sources in equatorial coordinates. Shown are 1230+ unique sources from the EUVE all-sky survey second catalog (Bowyer et al. 1996), Lampton et al. (1997) faint list, and sources from the second RAP catalog (Christian et al. 1999) (click here for a survey results page).



Geometry of the Survey Phase



The scanning telescopes are swept across the sky by the slowly revolving spacecraft, while the deep survey telescope is pointed down the Earth's shadow.

To conduct the all-sky survey, the EUVE slowly revolved around its axis, sweeping its three scanning telescopes in great circles across the sky. These repetitive scans, combined with the Earth's orbital motion around the Sun, allowed the scanning telescopes to map the entire celestial sphere within about six months. Utilizing four band passes, the three scanning telescopes observed the sky over the entire extreme ultraviolet range (60-740Å).

Accomplishing the deep survey, however, was more challenging. The geocoronal glow, caused by sunlight that strikes the diffuse hydrogen and helium gas atoms surrounding the Earth, makes it difficult to observe faint EUV sources. Consequently, scientists configured the mission so that the deep survey telescope always pointed away from the Sun and only took measurements while viewing down Earth's shadow - the night portion of the orbit when the Earth blocks the Sun and shields the spacecraft from sunlight. This technique made the deep survey more sensitive by a factor of ten. Utilizing two band passes, the deep survey telescope observed a portion of the extreme ultraviolet range (70-365Å).

EUVE Gallery of Pictures

- Cygnus supernova remnant (53 kbyte image)

  A false-color image of the Cygnus Loop supernova remnant. The extreme ultraviolet (EUV) light seen in the image originates from gas that was heated to very high temperatures by a supernova explosion. The temperature of the gas is between 1 and 5 million degrees Celsius.

- Vela supernova remnant (113 kbyte image)

  A false-color image of Vela supernova remnant. The EUV light seen in the image originates from gas that was heated to very high temperatures by a supernova explosion. The temperature of the gas is between 1 and 5 million degrees Celsius.

- Moon

  The first-quarter Moon (30 kbyte image). During the all-sky-survey portion of its mission, EUVE scanned the Moon. While not a natural source of EUV light, the Moon does reflect sunlight at these wavelengths, providing an indirect method of studying variations in our star. Direct observation of the Sun would burn out EUVE's detectors. This image was created by combining 17 observations at various wavelengths.

  The full Moon (54 kbyte image). This image was taken with EUVE's Deep Survey telescope just after the lunar eclipse of 10 December 1992. Notice that the bright regions correlate well with the lunar highlands and the dark regions with the maria.

- All-Sky Survey Sky Map (428 kbyte image)

  This is an image of the entire celestial sky, as it appears in the extreme ultraviolet. In addition to stellar objects, the Cygnus loop and Vela supernova remnants are visible. The image was created by combining EUVE scans of many small strips of the sky. These scans were taken during the all-sky-survey portion of the EUVE mission. The black strips are data gaps.

- EUVE image of the Hyades Cluster (119 kbyte image)

  This image is an EUVE Deep Survey observation of the Hyades Star Cluster. The diagonal strip in the middle of the image represents data taken with a particular filter, whilae that in the corners is from another filter. At least eight other sources are seen and marked with probably identifications. Some stellar images have a tri-lobed appearance due to the highly curved focal surface of the grazing incidence Deep Survey telescope mirror. The faintest star (M 25 VA 41) is detected in the EUV at about 1 count per 1,000 seconds.

- Map of Sources (16 kbyte image)

  Aitoff projection of EUVE all-sky and deep survey detections plus Right Angle Program detections, through July 1998.

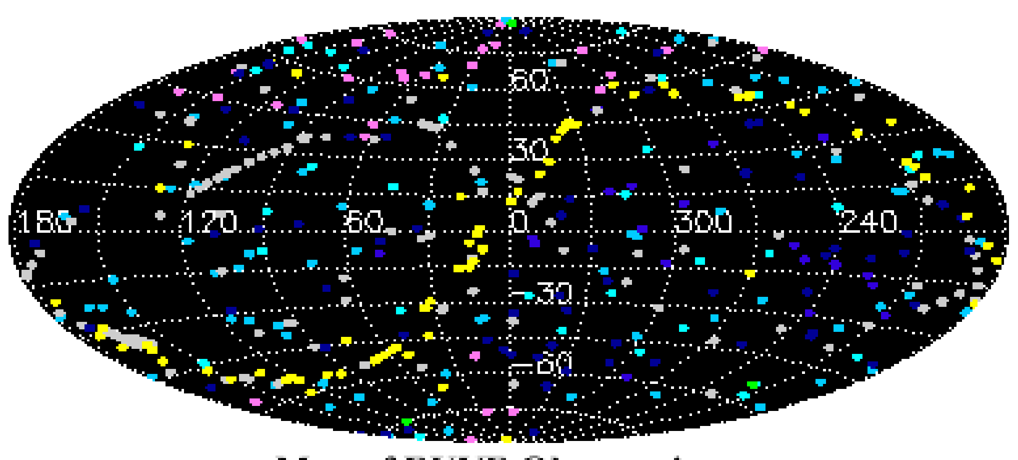
Launched in June, 1992, The ***Extreme Ultraviolet Explorer (EUVE)*** conducted the first extreme ultraviolet (70-760 Angstroms) survey of the sky and subsequently began a Guest Observer Program of pointed spectroscopy, that ended on January 31, 2001. The satellite has four photometric imaging systems and a three-channel EUV spectrometer. The imaging instruments were used to complete the sky survey. The spectrometers were used for the pointed spectroscopic programs, which collected data from over 350 unique astronomical targets.



Map of EUVE Observations

The ***ASTRO Observatory*** had three primary instruments: the Ultraviolet Imaging Telescope (UIT), the Hopkins Ultraviolet Telescope (HUT) and the Wisconsin Ultraviolet Photo-Polarimeter Experiment (WUPPE). The Astro Observatory was designed to use many of the spacelab components and flew on two different shuttle flights. The first Astro flight was on December 2-11, 1990, aboard the shuttle Columbia. The X-ray experiment Broad Band X-Ray Telescope (BBXRT) was also part of the Astro-1 flight. The second flight was on March 2-18, 1995, aboard the shuttle Endeavour.

HUT obtained ultraviolet spectra of astronomical objects such as quasars, active galactic nuclei, and supernova remnants, extending into the little-explored ultraviolet range below 1200 Ångstroms. The instrument consisted of a telescope, prime focus spectrograph, and intensified photodiode array. Scientific studies have included research on the cores of active galaxies (where black holes likely reside), the torus of gas around Jupiter created by its moon Io, the characteristics of the intergalactic medium, and the stellar population in elliptical galaxies.

UIT consisted of a telescope and two image intensifiers with 70 mm film transports. The instrument acquired images of faint objects in broad ultraviolet bands in the wavelength range of 1200 to 3200 Ångstroms. Astronomers have investigated the present stellar content and history of star formation in galaxies, the nature of spiral structure, and non-thermal sources in galaxies using UIT data.

WUPPE obtained both ultraviolet spectra and polarimetry for celestial objects such as hot stars, galactic nuclei, and quasars. The instrument included a telescope, spectropolarimeter, and dual diode array detectors. Researchers have studied the interstellar medium, mass loss from hot stars, interacting binary stars, and active galaxies, among other topics.

Getting Started with HUT

The Hopkins Ultraviolet Telescope (HUT) was the spectrographic component of a triad of coaligned telescopes that flew in Space Shuttle missions during December 1990 and March 1995. HUT was designed to overlap and extend to short wavelengths the coverage of previous ultraviolet missions and was contemporaneous with the **IUE** satellite. The HUT missions were instrumental in helping to define the key science requirements of the **FUSE** satellite.

Target fluxes were detected by photoamplification of bursts produced by a phosphor and scanned at a video rate. The phosphor bursts are time-tagged, accumulated, and located by a centroid-finding routine in two dimensions. The centroid positions are computed to bins of 1/4 of the physical pixel spacing of the detector, thus producing a partially-processed, 1 x 2048 spectrum in the first ('raw') data file that the user sees.

The **search** form may be used to select data from the HUT database by object name, coordinates, date of observation, or target class (general). The data files of interest can then be marked and retrieved. The returned dataset will consist of several type of files, which are described in the **Data Products** page. For bright objects an investigator's scientific objective can usually be met without doing a careful subtraction of geocoronal Lyman alpha. For fainter targets it is often necessary to start with the uncalibrated data and subtract an appropriate Lyman alpha and air glow background spectrum. User requests generate a tar file consisting of gzipped fits file of all possible files. For most purposes a user might want to work with just the following files:

object_[N,D,A]_METsum_imcscor.ph
object_[N,D,A]_METsum_imcscor.ct
object_[N,D,A]_METsum_imcslya.ct

and relevant calibration data files. The nomenclature referred to is defined in the data types page. (D, N, A is shorthand for observations made during the day side, night side, or 'combined' sides of the orbit.) This nomenclature is defined in the **Data Products** page. Because of its generally better quality, users will in general prefer ASTRO-2 data of a given object to ASTRO-1.

archive@stsci.edu
Modified: Jun 22, 2001 11:20

Search and Retrieval

HUT data of interest may be found by **searching** the MAST HUT database. As explained in the **Search Help** page, users may specify search criteria and output format. On the search results page, users may mark datasets of interest to be downloaded as a tar file.

A **"quick search"** of the HUT catalog may be performed by entering a target name or coordinates in the form labeled HUT Target Search at the top of the left navigation menu.

Users may also peruse a **Catalog** of HUT data. Pick an object category and click on object names or datasets. Clicking on the object name brings up a preview window while clicking on datasets initiates a pop-up window and the data can be downloaded to the desired area in your computer.

HUT Catalog

The following catalog lists the objects observed by the Hopkins Ultraviolet Telescope during the two ASTRO missions. A preview of the spectrum may be viewed by clicking on the object name. The data may be retrieved by clicking on the dataid.

The observations are grouped by categories as designated by the HUT project.

List all changes for HUT

More MAST mission data now on-line
2002 February 27
All IUE, UIT, BEFS and VLA-FIRST data are now on-line on a RAID array. The response time for data downloads for these missions should improve significantly. Data for missions HUT, WUPPE, TUES, and Copernicus were already on-line. HST and FUSE data remain on DADS and response times for data download for these two missions are not affected. EUVE data are held at HEASARC and this data is also not affected.

Name Resolver Option Available in Cross Correlation search
2002 January 15
The cross correlation search option available from the top MAST page now allows a choice of NED or SIMBAD for resolving user-specified target names. (The previous version only used SIMBAD.)

New MAST/ADS Data Links
2002 January 11
The ADS data links to data archived winthin MAST have been revised. Now a link to a single MAST page is shown which displays all the known MAST references for a single bibcode. (See 1995ApJ...449..488R as an example.)

New Plotting Option Offered in MAST Scrapbook
2001 October 18
A new option for coplotting multiple spectra and adjusting plot scales is now available in the MAST scrapbook.

Data Characteristics Plots Updated
2001 June 13
The MAST Data Characteristics plots have been updated to include the FUSE, TUES, BEFS, and SDSS missions.

Target Search Error
2001 June 12
An error was discovered in the target search available from the main MAST page. Searches would fail for object names containing special characters (such as a "+" symbol as in BD +28 4211). The error was fixed on the above date.

Implementation of Redesigned MAST Web Site
2001 June 4
The MAST redesigned web site is now online. The new dynamically-generated pages feature a common page layout, options for site-wide index searches, mission-specific target name searches, easier site navigation, and a printer-friendly page display option.

HUT Literature Links Updated
2001 February 26
The HUT reference database table entries (and ADS data links) are now complete through year 2000.

Customized HUT previews now available
2001 February 13
The interactive plotting option offered on IUE and EUVE preview pages is now available for HUT previews.

Corrections to HUT ASCII Files of Fluxes and Wavelengths
2000 November 14
An error was discovered in the way fluxes and error estimates were stored in the HUT ASCII table files. Instead of values being written as two columns of flux1, error1, flux2, error2, ..., the entries were stored as flux1, flux2, flux3, flux4,... error1, error2,... Corrected files are now available. The file creation date listed on the first line of the file can be used to distinguish the old and new files.

Cross Correlations with Sky2000 Catalog
2000 August 16
Cross correlations of MAST missions with the SKYMAP Sky2000 catalog (version 3) are now possible from the MAST Cross Correlation page.

HUT Journal References now Available
2000 July 24
A new column called "Ref" has been added to the HUT search results page showing the current number of known papers for each HUT data ID. Clicking on an entry (other than a "-") will display the list of known papers with links to the online ADS abstracts.

New Copyright Notice
2000 May 12
STScI has adopted a new Copyright statement. Most, if not all, MAST web pages should now include a link to the new page.

HUT catalog now available.
1999 November 11
A catalog of HUT observations has been constructed. Users may preview and retrieve data from the catalog.

HUT preview spectra now available.
1999 November 1
Preview spectra are now available from the HUT search results page for most HUT 1 & 2 observations.

HUT2 data is now available.
1998 November 18
Data acquired by HUT during the second ASTRO flight is now available.

Description of HUT1 filetypes is now available.
1998 November 10
A description of the files available for HUT1 data are described from information received from the HUT project.

HUT-1
1998 September 22
Data from the ASTRO-1 Hopkins Ultraviolet Telescope (HUT) can now be requested from MAST.

Frequently Asked Questions

Mission

Data Handling

Data Characteristics

Mission

- ***What is HUT and What Does it Do?***
  See the HUT project answer.
- ***What is the history behind HUT?***
  See the HUT history page.
- ***Where can I find a HUT Technical Summary?***
  See the HUT technical summary page. A detailed view of the HUT2 telescope module can be seen in the hardware chapter of the HUT data handbook. or alternatively in the HUT instrument and operations page.
- ***What are some major publications using HUT data?***
  See the HUT publications page. Note also the papers by Kruk et al. on final calibration of HUT 1 and HUT-2 (ApJS, 122, 299) data.

Data Handling

- ***How do I retrieve HUT data?***
  Data retrieval proceeds in much the same way as most other MAST-archived datasets. Go to the how to search HUT data page for instructions and the HUT search page for downloading of data. Data will be returned very quickly in a tarred file consisting of many zipped data files and an ASCII filetypes.txt file explaining some of the contents. For further information go to the HUT data products page.
- ***How do I read HUT data?***
  See the HUT data reading page.

Data Characteristics

- ***What are the instrumental error sources in HUT data?***
  - Unwanted time-dependent signals (dead time, phosphor persistence).
  - Airglow in emission lines (geocoronal Lyman alpha can be the dominant feature in the spectrum).
  - Extreme UV contamination (white dwarf only; corrected from model atmospheres estimates).
  - Telluric absorption (yes, there is atmosphere above the Shuttle!).
  - Flux loss from field astigmatism (extended sources only).
  - pointing-jitter errors (jitter corrected every 2 secs).

  The calibrated data consist of corrections for all these error sources. See the calibration chapter of the HUT data handbook.
- ***Did HUT lose sensitivity during its missions?***
  Yes, the losses were noticeable on an approximately 48 hour timescale, particularly in the far-UV. This is modeled in Figure 5 of Kruk et al. (ApJS, 122, 299, 1999). By the end of the mission the sensitivity of the detector (CsI photocathode) had decreased by 26% at 912 Å and 5% at 1840 Å.
- ***What were the differences between HUT1 and HUT2?***
  The second mission:
  - lasted longer (16 days compared to 8 days; 205 hours of on-target time vs. 40 hours).
  - made more observations (385 of 265 targets, compared to 136 of 87 targets).
  - had greatly improved pointing stability.
  - had less sensitivity to extreme-UV contamination because of SiC coatings on the optical elements.

Data Reduction/Analysis

Data Reduction Software

HUT data was reduced by the HUT project using IRAF with a HUT package. This package may be downloaded via anonymous ftp.

Reduced HUT software can be read and analyzed with either IRAF or IDL. Information about reading HUT data with these two packages has been provided.

The ***Hopkins Ultraviolet Telescope HUT*** was one of three ultraviolet instruments of the ASTRO-1 mission flown on the space shuttle Columbia during 2-10 December 1990. 106 spectrophotometric observations of 77 targets were obtained in the far-UV (i.e., 912-1850 Å) at a resolution of ~3 Å. A few sources were observed in the 415-912 Å region with a 1.5 Å resolution. The same three instruments were later flown on the space shuttle Endeavour from 3-17 March 1995 as part of the ASTRO-2 mission. During the longer ASTRO-2 mission, 385 observations of 265 targets were obtained.

Getting Started

The Ultraviolet Imaging Telescope (UIT) was the imaging component of the three **ASTRO** ultraviolet telescopes that flew on Space Shuttle missions in December 1990 and March 1995. The instrument was well suited to the study of large extended objects: globular clusters, reflection nebulae, supernova remnants, galaxies, and clusters of galaxies. The large field of view and ultraviolet bandpass make the UIT images a unique dataset, complementary to other imaging instruments such as HST's WFPC.

The MAST holdings include over 1500 ultraviolet images of 243 targets. The field-of-view is circular with a diameter of 40 arcmin and a nominal resolution of 3 arcsec. Two cameras, each with 6 filters, provide a range of effective wavelengths and bandpasses in the near- ("A" camera) and far-ultraviolet ("B" camera). Of these, the broad-band A1, B1 and B5 filters were used for most of the images. The images were recorded on Kodak IIa-O film, then developed and digitized. The data were flat-fielded, linearized, and when possible absolutely calibrated, geometrically rectified, and rotated to create fully reduced images with orthogonal RA and Dec axes and uniform plate scale.

The **search** form may be used to select data from the UIT catalog by object name, coordinates, filter, date of observation, etc. In addition, users may browse the **Catalog** or download the images using **anonymous ftp**.

The images are archived as FITS files. Several versions of the images are available as captured at various stages during the image processing. Not all the images could be fully calibrated, so users should check the file names (see **Data Products**) and FITS headers to determine what reduction and calibration steps were applied.

Search and Retrieval

UIT data of interest may be found by **searching** the UIT database. Users may specify search criteria as well as output format (see **Search Help**). On the search results page, click on the Entry ID to view a browse image, examine the FITS header, or check for associated scientific publications. Then mark the datasets of interest to be downloaded as a tar file. Note that UIT files can be very large.

A **quick search** of the UIT catalog may also be performed. Enter a target name or coordinates in the UIT Target Search form, located at the top of the left navigation menu.

Users may also peruse the **catalog** of UIT data. Pick an object category and click on object names or datasets. Clicking on the object name brings up a preview window, while clicking on datasets initiates a pop-up window from which the data can be downloaded to the desired area in your computer.

The data may also be retrieved via **anonymous ftp**. See **Obtaining UIT Data** for information.

UIT Catalog of Observations

The following catalog lists the objects observed by the Ultraviolet Imaging Telescope during the two ASTRO missions. A preview of the spectrum may be viewed by clicking on the object name. The data may be retrieved by clicking on the dataid.

The observations are grouped by categories as designated by the UIT project.

- Calibration
- Solar System
- Individual Stars
- Variable & Binary Stars
- ISM & Nebulae
- Star Clusters
- Normal Galaxies
- Abnormal Galaxies
- Active Extragalactic
- Clusters of Galaxies

Mission/category: UIT all Go

List all changes for UIT

More MAST mission data now on-line
2002 February 27
All IUE, UIT, BEFS and VLA-FIRST data are now on-line on a RAID array. The response time for data downloads for these missions should improve significantly. Data for missions HUT, WUPPE, TUES, and Copernicus were already on-line. HST and FUSE data remain on DADS and response times for data download for these two missions are not affected. EUVE data are held at HEASARC and this data is also not affected.

Name Resolver Option Available in Cross Correlation search
2002 January 15
The cross correlation search option available from the top MAST page now allows a choice of NED or SIMBAD for resolving user-specified target names. (The previous version only used SIMBAD.)

New MAST/ADS Data Links
2002 January 11
The ADS data links to data archived winthin MAST have been revised. Now a link to a single MAST page is shown which displays all the known MAST references for a single bibcode. (See 1995ApJ...449..488R as an example.)

New Plotting Option Offered in MAST Scrapbook
2001 October 18
A new option for coplotting multiple spectra and adjusting plot scales is now available in the MAST scrapbook.

Updated UIT Data Analysis Software
2001 August 6
An updated version of the Exported MOUSSE IDL Software is now available to users. See the UIT Data Reduction/Analysis page for details.

UIT added to scrapbook
2001 August 1
Representative images from the UIT mission have now been added to the MAST scrapbook.

Data Characteristics Plots Updated
2001 June 13
The MAST Data Characteristics plots have been updated to include the FUSE, TUES, BEFS, and SDSS missions.

Target Search Error
2001 June 12
An error was discovered in the target search available from the main MAST page. Searches would fail for object names containing special characters (such as a "+" symbol as in BD +28 4211). The error was fixed on the above date.

Implementation of Redesigned MAST Web Site
2001 June 4
The MAST redesigned web site is now online. The new dynamically-generated pages feature a common page layout, options for site-wide index searches, mission-specific target name searches, easier site navigation, and a printer-friendly page display option.

UIT Literature Links Updated
2001 January 25
The UIT reference database table entries (and ADS data links) are now complete through year 2000.

Cross Correlations with Sky2000 Catalog
2000 August 16
Cross correlations of MAST missions with the SKYMAP Sky2000 catalog (version 3) are now possible from the MAST Cross Correlation page.

UIT Journal References Available
2000 July 18
A new column called "Ref" has been added to the UIT search results page showing the current number of known papers for each UIT data ID. Clicking on an entry (other than a "-") will display the list of known papers with links to the online ADS abstracts.

New Copyright Notice
2000 May 12
STScI has adopted a new Copyright statement. Most, if not all, MAST web pages should now include a link to the new page.

UIT preview images now available from MAST
1999 November 16
UIT preview images and FITS headers can now be displayed from the UIT search results page (prior to this date, the browse files were downloaded from the NASA ADF project).

UIT ASCII Logs available.
1998 October 21
In addition to the UIT search routines, you may find these ASCII listings of the UIT catalog useful. They maybe copied from our anonymous ftp area.

ASTRO-1 UIT Data now Available
1998 July 29
The ASTRO-1 UIT data is now available from MAST.

Browse Files Accessible from Search Page
1998 June 25
Users may now access ADF UIT browser from our search pages. Simply click on the highlighted object name and the browse file information for that image will be placed on the screen.

UIT-2
1998 June 1
Data from the ASTRO-2 Ultraviolet Imaging Telescope (UIT) can now be requested from MAST. ASTRO-1 UIT data will be added in the near future.

Frequently Asked Questions

Data Requests

- ***Why does it take so long to download the UIT files?***
  The combined files for each observation are fairly large, about 28 Mb compressed, 51 Mb uncompressed. If you need only one file for a given observation, such as the fully calibrated and geometrically corrected ("G") file, you may wish to obtain it from the anonymous ftp site (see Obtaining UIT Data).

- ***How can I tell which files are fully calibrated?***
  The easiest way is by the file name. The raw image (digitized densitometer output) filenames end in D, e.g. fuv0345d.fits. The linearized, flat fielded image filenames end in E (no good astrometry solution) and F (good astrometry solution). The fully calibrated, geometrically corrected image filenames end in G.

Reading Files

- ***How do I read the UIT data files?***
  The image files are in FITS format, with the data stored in the primary arrays. The point-source photometry data are stored in ASCII table extensions, with no primary array. These simple FITS formats should be readable by a variety of FITS readers. See Reading UIT Data for more information.

Data Reduction/Analysis

Data Reduction

The UIT standard data products were produced using the Batch Data Reduction (BDR) software system. The processing steps included: (1) linearization of the data, (2) flat-fielding, (3), geometric correction of image distortions, (4) astrometric solution (mapping to RA and Dec), and (5) point-source photometry. For some images, an astrometric solution was not possible so subsequent processing steps were not performed. See also the discussion of UIT Data Products. The data reduction and calibrations involved are described in more detail in the 1997 PASP paper. An analysis of the geometric correction was published by Greason et. al. 1994.

Software

The UIT project archived three sets of software with the GSFC Archive (NDADS) with the UIT Astro 1 data. The UIT project has indicated that the software used for Astro 2 data was relatively unchanged. These software sets have been retrieved from NDADS (the updated MOUSSE software was provided by Wayne Landsman from Goddard Space Flight Center), and are available from MAST as gzipped tar files via anonymous ftp. The software packages were archived for documentation purposes and may require some revision to work outside the UIT project environment. The software is unsupported. Documentation is available as both postscript and tex files.

1. BDR Software

The Batch Data Reduction software, written in Fortran and C, was used to process UIT data and generate FITS output files.

bdr.tar.gz	Gzipped UNIX tar file containing software used in UIT batch data processing. Includes programs in FORTRAN and C, associated data files and documentation.
bdr_doc.ps, bdr_doc.tex, bdr_readme.txt	Description of BDR design and programs.
fits.ps, fits.tex	Description of FITS headers.
readme_cal.txt	Listing of calibration files used by the software.

2. Exported MOUSSE Software

The Multi-Option UIT Software System Environment was used by UIT team members to analyze their data. The programs are written in IDL and were meant to supplement the procedures contained in the ASTRON library.

export.tar.gz	Gzipped UNIX tar file containing IDL procedures used by the UIT team to manipulate and analyze UIT images; a data base program; and an on-line help facility.
export.ps, export.tex	Description of the IDL procedures used to display and manipulate UIT images. These are subset of IDL analysis system MOUSSE (Multi-Option UIT Software System Environment).
db.ps, db.tex	Description of an IDL database system.
ft.ps, ft.tex	Description of IDL routines for reading FITS table files.
phot.ps, phot.tex	Description of IDL point-source photometry programs, based on DAOPHOT.
mousse.ps, mousse.tex	A list of MOUSSE software likely to be used by interactive user.

3. IDL Version of BDR

This IDL version of the processing software was used for calibration and testing, such as quickly testing a sample characteristic curve on an image.

idlbdr.tar.gz	Gzipped UNIX tar file of IDL procedures and supporting files used to process a UIT density image through photographic background subtraction, linearization and flat field division.

In addition, users may find some of the IDL procedures in the ASTRON library useful.

Instrumentation and Operations

Telescope: The telescope is a 38 cm Ritchey-Chretien telescope, with a system focal ratio of f/9, effective focal length of 342.9 cm, and field of view of 40 arcmin.

Image Motion Compensation: An Image Motion Compensation (IMC) system stabilized the UIT pointing at a finer level than possible with the Spacelab Image Pointing System (IPS) on the shuttle. Two gyros and a CCD startracker were used to sense motion. A servomechanism that controls small tilts of the UIT secondary mirror was then commanded to maintain stable pointing. Pointing problems affected about a third of the UIT images, evidenced by asymmetric stellar images.

Filters: Each camera had 6 filter settings. The A6 filter wheel slot was empty to accomodate tranmsmission grating mode observations.

Filter	Effective Wavelength (Å)	Bandwidth (Å)	Number of Observations
A1	2488	1147	172
A2	1892	412	51
A3	1964	173	4
A4	2205	244	32
A5	2558	456	74
A6	Grating		15
B1	1521	354	455
B2	1359	160	2
B3	1445	256	2
B4	1585	129	10
B5	1615	225	610
B6	1496	404	54

Transmission Grating: The grating was ruled at 75 lines mm^{-1} on a CaF_2 substrate. The first order yields a linear dispersion of 840 Å, with a resolution of about 19 Å in the range 1400 - 3400 Å over a 35 arcmin field of view.

Cameras: Two detectors were used, each of which was a magnetically focused, two-stage image intensifer with phosphor output, coupled with fiber optics to 70mm film. The near-ultraviolet (NUV or "A") camera used a Cs_2Te photocathode, while the far-ultraviolet (FUV or "B") camera camera used CsI. The NUV camera failed at launch during ASTRO-2 and was not used during that flight. Both provided long-wavelength cutoffs that made the instrument solar-blind.

Film: The images were recorded on Kodak IIa-O film. The specially designed film transports each held about 1200 frames. The film was advanced by stepper motors. Annotation devices projected the frame count, exposure time, 30-step grey scale, and fiducial marks on each frame.

Further information about the UIT instrument and operations may be found in *Section 1. Introduction and UIT Overview* of the 1997 PASP article describing the UIT mission, as well as the earlier 1992 ApJ article describing its design and performance.

The ***Ultraviolet Imaging Telescope UIT*** was one of three ultraviolet telescopes on the ASTRO-1 mission flown on the space shuttle Columbia during 2-10 December 1990. The same three instruments were later flown on the space shuttle Endeavour from 3-17 March 1995, as part of the ASTRO-2 mission. Exposures were obtained on 70-mm photographic film in the 1200-3300 Å range using broadband filters and later digitized using a Perkin-Elmer microdensitometer. Image resolution was 3" over a 40' field of view. Overall, UIT-1 obtained 821 exposures of 66 targets, and UIT-2 obtained 758 images of 193 targets.

About Astro

Acknowledgments

Getting Started

The Wisconsin Ultraviolet Photo-Polarimeter Experiment (WUPPE) was the spectropolarimetry component of the three ASTRO instruments that flew on Space Shuttle missions in December 1990 and March 1995. A halfwave spectropolarimeter provided medium resolution spectropolarimetry for research into the interstellar medium, hot stars, stars with circumstellar material, interacting binary stars, novae, solar system objects, and active galaxies. A Lyot analyzer obtained low resolution observations of faint targets, but due to calibration problems did not produce scientifically useful data. The WUPPE instrument provides a unique data set, one of the few providing polarimetric data in the ultraviolet portion of the spectrum.

The MAST holdings include 238 WUPPE observations of 160 targets obtained with the halfwave spectropolarimeter. Of these, useful spectropolarimetric data are available for 121 targets. Ultraviolet spectrophotometry only is available for the remainder. The data cover a wavelength range from 1400 to 3300 Å, with a spectral resolution of 16 Å. The flux calibration is based primarily on the original IUE (IUESIPS) flux calibration. The polarization was calibrated on the ground and in flight, the latter by observing stars known to be unpolarized in the visible and by observing heavily polarized stars with nearly simultaneous ground-based polarimetric observations.

The search form may be used to select data from the WUPPE catalog by object name, coordinates, type of object, date of observation, etc. Click on the Entry ID to view the spectrum, degree of polarization, and polarization position angle plotted as functions of wavelength.

The data are archived as FITS files. In addition, ASCII files of the data and Postscript plots depicting the polarization and spectrum are provided as part of the standard data product. See Data Products and Reading WUPPE Files for more information.

Search and Retrieval

WUPPE data of interest may be found by **searching** the WUPPE database. Users may specify search criteria as well as output format (see **Search Help**). On the search results page, click on the Entry ID to view a browse file displaying the ultraviolet spectrum, degree of polarization and position angle of polarization, binned either by wavelength or error estimate. Then mark the datasets of interest to be downloaded as a tar file.

A **quick search** of the WUPPE catalog may also be performed. Enter a target name or coordinates in the WUPPE Target Search form, located at the top of the left navigation menu.

Users may obtain an ASCII version of the **WUPPE catalog**, sorted either by coordinates or category, via **anonymous ftp**.

WUPPE data files may also be retrieved via **anonymous ftp**. See **Obtaining WUPPE Data** for information.

WUPPE ASCII Catalogs

The series of ASCII Catalogs contain summaries of the WUPPE observations obtained from the WUPPE database. Catalogs of all WUPPE observations sorted by coordinates and sorted by WUPPE category are available via ftp.

Log	Sort
Total Uncompressed (34 kbytes) GZIP Compressed (8 kbytes)	Coordinates
Category Uncompressed(34 kbytes) GZIP compressed(8 kbytes)	ASTRO classification

The fields contained in the logs are listed below.

FIELD	DESCRIPTION
Object_name	target name assigned by the ASTRO team
RA,DEC	RA and Dec of target (J2000)
Observation Date	Date and time of observation start
Exposure Length	The total useable exposure times in seconds.
Mean % Polarization	Mean percent polarization averaged over approximately 1450-3200 Å (calculated for halfwave data only).
Mean Error	Mean error in percent polarization averaged over approximately 1450-3200 Å
Category	A broad astronomical category assigned by the the ASTRO team. These categories were incoded into the pointing id which is included in this log as part of the data ID. The translation of the pointing id is included in this version of the WUPPE log.
Data ID	The WUPPE entry_id uniquely defines each WUPPE observation. The name is of the form MISSION-OBJECTID-nnnnnn where • MISSION = either WUPPE1 or WUPPE2 • OBJECTID = object name (e.g., GAM-GEM or NGC4151), identical to the entries under "Target Name", • nnnnnn = a unique six-digit number (also known as the pointid), based on the 2-digit ASTRO Science Class, a 2-digit preassigned target number for a given science class (although some targets have more than one target number), and a 2-digit pointing number (i.e., jotfid) for a particular target. The first digit of the pointing number is a sequential number indicating the nth observation at a particular roll angle, and the second digit is the nth exposure at that roll angle. As an example, entry_id WUPPE1_HD5980_226911 designates an observation of HD5980, which is in science class 22, was the 69th selected target in class 22, the first observation at a given roll angle, and the first observation at that roll angle. Within the ASTRO project, the number 226911 would be referred to as the pointid and the jotfid is 11.

List all changes for WUPPE

WUPPE Added to MAST Scrapbook
2002 March 15
Representative spectra from the ASTRO WUPPE mission have been added to the MAST scrapbook available at http://archive.stsci.edu/scrapbook.html

New WUPPE Preview Files
2002 February 28
The WUPPE Preview files have been updated following the format adopted for the other MAST missions. Besides a plot showing flux, polarization, and polarization position angle as a function of wavelength, there are now links to display the FITS header, display the ASCII table file, display/customize a plot of flux versus wavelength, and download data in FITS format. Links to known literature references are also displayed.

More MAST mission data now on-line
2002 February 27
All IUE, UIT, BEFS and VLA-FIRST data are now on-line on a RAID array. The response time for data downloads for these missions should improve significantly. Data for missions HUT, WUPPE, TUES, and Copernicus were already on-line. HST and FUSE data remain on DADS and response times for data download for these two missions are not affected. EUVE data are held at HEASARC and this data is also not affected.

Name Resolver Option Available in Cross Correlation search
2002 January 15
The cross correlation search option available from the top MAST page now allows a choice of NED or SIMBAD for resolving user-specified target names. (The previous version only used SIMBAD.)

New MAST/ADS Data Links
2002 January 11
The ADS data links to data archived winthin MAST have been revised. Now a link to a single MAST page is shown which displays all the known MAST references for a single bibcode. (See 1995ApJ...449..488R as an example.)

New Plotting Option Offered in MAST Scrapbook
2001 October 18
A new option for coplotting multiple spectra and adjusting plot scales is now available in the MAST scrapbook.

Data Characteristics Plots Updated
2001 June 13
The MAST Data Characteristics plots have been updated to include the FUSE, TUES, BEFS, and SDSS missions.

Target Search Error
2001 June 12
An error was discovered in the target search available from the main MAST page. Searches would fail for object names containing special characters (such as a "+" symbol as in BD +28 4211). The error was fixed on the above date.

Implementation of Redesigned MAST Web Site
2001 June 4
The MAST redesigned web site is now online. The new dynamically-generated pages feature a common page layout, options for site-wide index searches, mission-specific target name searches, easier site navigation, and a printer-friendly page display option.

Cross Correlations with Sky2000 Catalog
2000 August 16
Cross correlations of MAST missions with the SKYMAP Sky2000 catalog (version 3) are now possible from the MAST Cross Correlation page.

New Copyright Notice
2000 May 12
STScI has adopted a new Copyright statement. Most, if not all, MAST web pages should now include a link to the new page.

WUPPE publication list updated
2000 May 9
The WUPPE publication list has been updated. Additional ADS links have also been included.

WUPPE-1 & 2
1998 September 22
Data from the ASTRO-1 and ASTRO-2 Wisconsin Ultraviolet Photo-Polarimeter Experiment (WUPPE) can now be requested from MAST.

Frequently Asked Questions

Data Requests

Reading Files

Data Requests

- ***How can I tell whether polarization data, as well as the UV spectrum, are available for a particular object?***
  In the search results page, the polarization and position angle will both be set to 0.000 if no polarization data are available. In this case, only the ultraviolet spectrum is available from the archive. In addition, the FITS file for an observation including polarization data is significantly larger (typically 34560 bytes uncompressed) than one with only spectral data (11520 bytes).

Reading Files

- ***How do I read the WUPPE data files?***
  The image files are in FITS format, and should be readable with standard FITS readers. See Reading WUPPE Data for more information.

- ***How do I convert the Stokes parameters Q and U to linear polarization parameters?***
  Linear polarization = sqrt($Q^2 + U^2$), while position angle = 1/2 $\tan^{-1}$(U/Q)

Getting Started

Launched in August 1972, almost 6 years before IUE, the third Orbiting Astronomical Observatory (otherwise known as Copernicus) represents one of the oldest archives of astronomical UV spectra and is the oldest mission within MAST. Before ending operations in 1981, multiple observations were obtained of 551 targets ranging in brightness from -1.5 to 7th magnitude. Six single-channel detectors were used (U1,U2,U3,V1,V2,V3 with U3 and V3 mainly used for monitoring) covering the wavelength range from 900 to 3150 Angstroms. (See instrumentation/operations for more information.) The most useful Copernicus data is generally considered to be the high resolution U1 and medium resolution U2 scans which covered subsets of the 900-1600 Angstrom range. Individual Copernicus scans could begin anywhere within the prescribed wavelength range and proceeded by stepping up or down in wavelength every 14 seconds. Individual scans generally covered only a few Angstroms (i.e., they contained 14-350 points, with most containing less than 75 points). Observations were typically centered around specific interstellar lines. Occasionally a series of overlapping scans were taken to obtain a more complete spectrum of the target. The most observed target, Zeta Oph, has close to 23,000 spectral scans. A complete target list sorted by right ascension, and spectral coverage plots which give an indication of the U1 & U2 spectral coverage, are available. .

Each Copernicus raw data FITS file contains all the scans for one particular target. The scans are stored chronologically with the earliest scans first. Usually an observer would take a set of scans, once with each detector, and then repeat the process at various wavelengths. As part of a recent ADP program, the U1 and U2 scans were extracted, the contemporaneous scans were coadded, and the results were stored in a separate set of FITS files. The Copernicus spectral atlas files containing data published in the six spectral atlas papers by Rogerson, et al, represent a third set of archived data. More information is available on data products, and reading and retrieving Copernicus files.

Caveats

- Except for some of the spectral atlas data, Copernicus spectra are not calibrated or corrected for scattered light.
- The raw data FITS files use the "variable length array facility" which has not yet been adopted as an official FITS format and may not be readable by all FITS readers.
- The coadded scan FITS files use vector fields in a binary table FITS file, which, although adopted as an official FITS format, may not be readable by all FITS readers.
- The Copernicus detectors severely degraded with time, so observations obtained in the first few years generally have the highest S/N. This also implies that scans taken far apart in time are not suitable for coadding.
- Because the observations are scanned, each wavelength increment is observed roughly 14 seconds before and after its neighbor. Certain instrumental errors can therefore accrue across the spectrum (e.g., passage into the South Atlantic Anomaly),
- Stray light was found to be a problem with some U1 scans, but observing methods were adopted that effectively "blocked" the stray light. For this reason U1 scans were classified as either "blocked" or "unblocked" and the two were not coadded.
- Accurate observations times may require a time correction.
- Investigators are encouraged to read the page on data problems before analyzing Copernicus data.

Extracting Spectral Scans

This page allows users to extract and display spectral scans from the Copernicus Raw, or Coadded Scan, FITS files. To run the form however, users must know either the 3-digit target number, or a coadded scan file name.

Submitting the form below with a coadded scan file name (as shown), will display a second form containing a list of the original scan numbers used in the coadded scan. Submitting a 3-digit target number will display the second form with the scan number for the specified target set to 1. In either case, the scan number(s) can be modified. If more than one scan is specified, the spectra will be coadded. Various processing and display options are also available.

Submitting the 2nd form, will display a plot of counts vs wavelength. The extracted data can also be downloaded as an ASCII table file.

Target Number or Coadded Scan File Name: c084-003.bu1

2002 January 15
The cross correlation search option available from the top MAST page now allows a choice of NED or SIMBAD for resolving user-specified target names. (The previous version only used SIMBAD.)

New MAST/ADS Data Links
2002 January 11
The ADS data links to data archived winthin MAST have been revised. Now a link to a single MAST page is shown which displays all the known MAST references for a single bibcode. (See 1995ApJ...449..488R as an example.)

New Plotting Option Offered in MAST Scrapbook
2001 October 18
A new option for coplotting multiple spectra and adjusting plot scales is now available in the MAST scrapbook.

Data Characteristics Plots Updated
2001 June 13
The MAST Data Characteristics plots have been updated to include the FUSE, TUES, BEFS, and SDSS missions.

Target Search Error
2001 June 12
An error was discovered in the target search available from the main MAST page. Searches would fail for object names containing special characters (such as a "+" symbol as in BD +28 4211). The error was fixed on the above date.

Implementation of Redesigned MAST Web Site
2001 June 4
The MAST redesigned web site is now online. The new dynamically-generated pages feature a common page layout, options for site-wide index searches, mission-specific target name searches, easier site navigation, and a printer-friendly page display option.

New Coadded Scan Browse Files
2000 August 30
The Copernicus coadded scan browse files have been revised to use the same format used by the other MAST missions. The new pages include several new links as well as a new help page, and are accessible from the Copernicus coadded scan search page.

Cross Correlations with Sky2000 Catalog
2000 August 16
Cross correlations of MAST missions with the SKYMAP Sky2000 catalog (version 3) are now possible from the MAST Cross Correlation page.

Updated Copernicus Bibliography
2000 August 8
The Copernicus Bibliography list has been updated. The new list includes papers from 1972 to July, 2000, and includes links to online ADS papers.

Links to ADS Spectral Atlas Papers
2000 June 19
Links to the Copernicus spectral atlas papers available from the ADS have been added to the Spectral Atlas pages. Links from the ADS papers to the MAST spectral atlas pages are also available.

New Copyright Notice
2000 May 12
STScI has adopted a new Copyright statement. Most, if not all, MAST web pages should now include a link to the new page.

More IDL Copernicus Routines
1999 May 6
Selected IDL Routines have been added to the anonymous ftp area on archive.stsci.edu. A summary of all the available programs is contained in the README file.

Early Copernicus Memos Scanned and Online
1999 February 09
Selected Copernicus memos provided by Ed Jenkins form the Princeton University Observatory, have been scanned (courtesy of Jim Caplinger, CSC) and are now available online.

Customized Coadded Scan Option
1998 October 30
There is now an option to customize coadded scans. To use, search the coadded scan database for the desired data, click on the object name for a particular coadded scan shown on the results page, click on the button labeled "customize coadded scans" on the page showing a plot of counts versus wavelength. This will display a forms page with an editable list of scan numbers which comprised the original coadded scan. Several processing options and plot display modes are also offered. Clicking the "submit form" button will display a new plot of the counts versus wavelength and show an option to download the new coadded spectrum as an ASCII table.

If the coadded scan file name is already known, start at the Copernicus Spectral Scans page and enter the file name. This will display the same forms page described above.

Acknowledgments Page added
1998 October 30

Revised Spectral Atlas Files
1998 October 9
Errors were corrected in the Copernicus Spectral Atlas FITS headers. Incorrect keyword values in the FITS extension headers caused floating point values to be displayed as integers, and the Tau Sco normalized counts to be incorrectly scaled from 1 to 1000 (rather than 0 to 1). The corrected Spectral Atlas files are now available online.

FAQ Page
1998 August 5
A Copernicus "Frequently Asked Questions" (FAQ) page is now available. Users should send additional questions to archive@stsci.edu.

New Documentation
1998 August 4
Excerpts from the Copernicus Ultraviolet Spectral Atlas of Tau Scorpii paper describing the photometric reductions used to produce the atlases are now online. Included is a general discussion on correcting for guidance variations.

Copernicus (OAO-3)
1998 January 30
The Copernicus archive of raw, coadded, and

spectral atlas data is now online and accessible from MAST. The ability to coadd user-specified scans and display the results will be coming soon.

Frequently Asked Questions

Data Requests

- Where do I get Copernicus archival data?
- How do I download the Copernicus Spectral Atlas Files?

Instruments

- What are the wavelength ranges of the Copernicus detectors?
- Did the instrument sensitivity significantly degrade with time?

Data Analysis

- How do I read a Copernicus FITS file?
- How do I coadd Copernicus Scans?
- How do I know what wavelength regions were observed for a particular object?

Data Requests

- ***Where do I get Copernicus archival data?***
  At the end of the mission, Princeton provided the National Space Science Data Center (**NSSDC**) with a compact set of data on 9-track tapes as the final archive of the *Copernicus* science mission. The data were formatted in such a manner that special programs were needed to extract the information, bit by bit, from the archive. Under a grant from NASA's Astrophysics Data Program, the **Laboratory for Astronomy and Solar Physics** and the **IUE Data Analysis Center** have converted the tape files into **FITS** format disk files and created an on-line archive of *Copernicus* ultraviolet spectra.

  There is one FITS file of raw scans for each of the 551 objects observed by *Copernicus*. These files can be retrieved from the **raw target list**, the **Copernicus search page**, and via the anonymous FTP at archive.stsci.edu in the **/pub/copernicus/raw** subdirectory. The FITS files containing the raw spectral scans are constructed using a Binary table extension and the proposed "variable length array facility" as described in the NOST FITS Draft Standard. Each row of the binary table contains the data from one spectral scan.

  In addition to the raw data files, coadded contemporaneous scans from the U1 high resolution channel (900-1560 Å) and U2 (900-1650 Å) channel are available from the **Copernicus Coadded Scan search page**, and via the anonymous ftp at archive.stsci.edu in the **U1 coadded scan directory** and the **U2 coadded scan directory** The files are stored as standard Binary table FITS files using fixed length vector fields. The files are intended primarily for quick-look data analysis.

- ***How do I download the Copernicus Spectral Atlas Files?***
  The spectral atlas files are available online from the **Copernicus spectral atlas page**. References to the original published papaers are also given. The files can also be retrieved via anonymous ftp at archive.stsci.edu in the **spectral atlas directory**. All the spectral atlas files use FITS binary table extensions with scalar fields.

Instruments

- ***What are the wavelength ranges of the Copernicus detectors?***
  The table below shows the spectral coverage of each detector. Note however that the individual scans generally covered a much smaller wavelength range.

Name	Exit Slit* (Å)	Wavelength (Å)	Step Size* (Å)
1 - U1	0.05	710-1500**	0.025
2 - V1	0.10	1640-3185	0.05
3 - U2	0.20	750-1645	0.20
4 - V2	0.40	1480-3275	0.40
5 - V3	?	3430 (fixed)	-
6 - U3	?	1320 (fixed)	-

  *****Note: Exit slit and step size vary slightly with wavelength.
  ******For brighter stars, the 1500-1560 angstrom range can be scanned with U1 in the first order.

- ***Did the instrument sensitivity significantly degrade with time?***
  The principal malfunction in the Copernicus instrumentation was the rapid decline in the far-UV sensitivity. The decision to terminate the spacecraft was based partly on the loss of far-UV sensitivity. The following **figure** shows the relative sensitivity of the high-resolution far-UV phototube U1 from orbits 100 to 44000. A rapid (approximately 50 percent) decline at shorter wavelengths was experienced during the first year followed by smaller declines in subsequent years. The low-resolution far-UV phototube U2 exhibited a behavior similar to that of U1. The near-UV phototubes, V1 and V2, did not exhibit the rapid decline seen in the far-UV phototube. For further information, see the **Final Operations Report**.

Data Analysis

- ***How do I read a Copernicus FITS file?***
  The raw data sets are probably the most difficult files to read since they use the proposed variable length array facility for storing vectors in a binary table extension. In any event, of how to read all the Copernicus data sets using a variety of FITS readers are available. Many users will want to work with individual scans. Examples of how to work with them are on the page just cited.

- ***How do I coadd Copernicus Scans?***
  The IDL program **STACK** allows U1 or U2 Copernicus scans to be coadded. This software was used to create the "quick-look" coadded scan files and is available to users from either the **Copernicus Spectral Scan** page (which currently requires you to know the name of a coadded scan file), or from the browse files accessible after searching the **coadded scan database**. In principle, STACK can coadd any Copernicus scans, however only scans taken close in time and using the same detector can produce meaningful results. For this reason, use of STACK is restricted to addiing or subtracting the existing sets of coadded scans.

- ***How do I know what wavelength regions were observed for a particular object?***
  The min and max wavelength for each scan is stored as scalar fields in the raw data sets (note wavelengths could be scanned in either direction, so some vectors are in order of decreasing wavelength). However, to help users determine wavelength coverage for U1 and U2 scans, a **spectral coverage table** was created. This can be a useful tool since most U1 scans only cover a couple of Angstroms, and U2 scans normally covered less than 50 Angstroms. The rows of the spectral coverage table represent the observed targets, while the columns list various wavelength regions. Each entry in the table shows the number of scans obtained in that particular spectral region and is also a link to a gif-format plot file showing the spectral range of each scan within that spectral region.

Copernicus Bibliography

Following is a list of 689 papers, published between 1972 and 2000, referencing the Copernicus mission. The listed bibcodes are links to the online ADS papers. Some references were obtained from the SIMBAD bibliographic database operated at CDS, Strasbourg, France. ADS links for some of these papers may not work.

Online access to the Copernicus archive was made possible by two NASA ADP programs:

- **"Access to the Far-Ultraviolet Universe: Three Far-UV Mission Data Sets"** (NRA 92-OSSA-15)
  - PI: George Sonneborn (NASA/GSFC),
  - Co-I's: Ron Polidan (NASA/GSFC), Susan Neff (NASA/GSFC), Dan Klinglesmith (NASA/GSFC), Michael Van Steenberg (NASA/GSFC), Randy Thompson (CSC), Carol Christian (EUVE), and Tim Carone (EUVE),
- **"Access to the Far-Ultraviolet Universe: Copernicus and Voyager/UVS Data Sets"** (NRA 94-OSSA-17)
  - PI: George Sonneborn,
  - Co-I's: Ron Polidan, Susan Neff, Dan Klinglesmith, Michael Van Steenberg, Ron Oliversen (NASA/GSFC), Randy Thompson, and Jay Holberg (LPL).

Special acknowledgment should be given to the following individuals:

- Ron Polidan and Ed Jenkins (Princeton), for invaluable advice, documentation, and information in general, on the Copernicus project,
- Dan Klinglesmith, for creating the original Copernicus raw data FITS files,
- The former CSC IUE Data Analysis Center staff including Jim Caplinger, Lyla Taylor, Pat Lawton, Mike Carini, and Terry Teays, for software and database development, creating the original Copernicus WEB site, and general testing.
- the Raytheon/STX ADF staff including Nancy Oliversen, Derck Massa, and Pat Lawton, for general advice on archiving mission data sets,
- Jim Lauroesch (Northwestern University), for describing and documenting several Copernicus data analysis problems and techniques, and
- John Rogerson (Princeton), for permission to reprint information from his Copernicus Spectral Atlas papers.

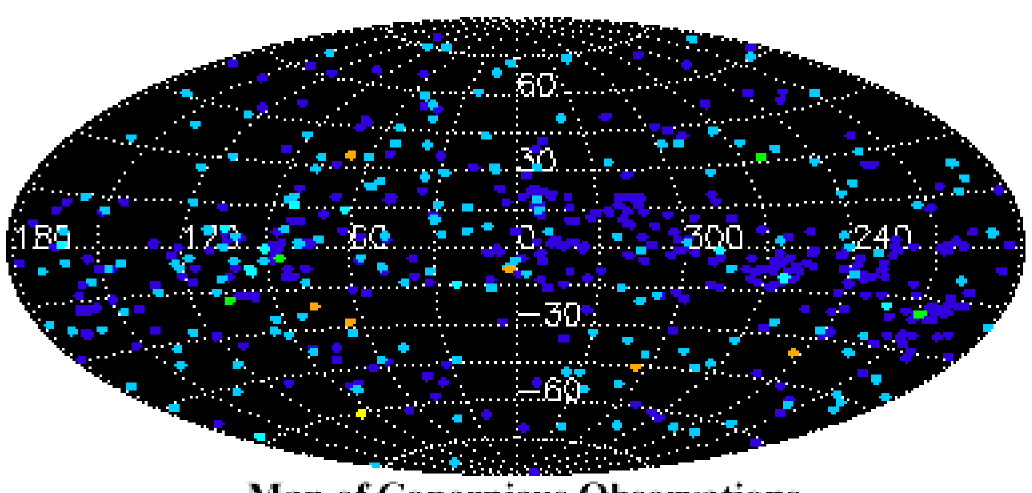
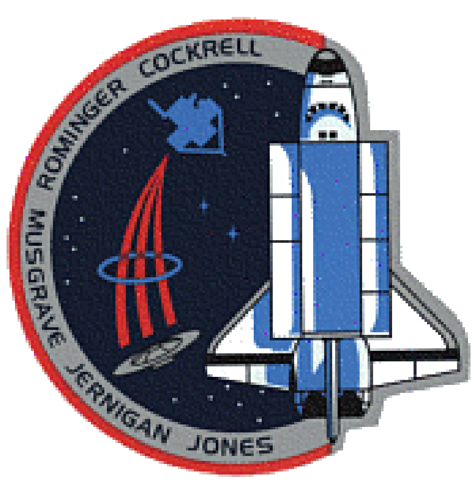
The ***Copernicus*** satellite, otherwise known as the Orbiting Astronomical Observatory 3 (OAO-3), obtained a series of high resolution far- (900-1560 Å) and near- (1650-3150 Å) ultraviolet spectral scans of 551 objects, primarily bright stars, from 1972 to 1981.



Map of Copernicus Observations

http://archive.stsci.edu/orfeus/

The ***Orbiting Retrievable Far and Extreme Ultraviolet Spectrometers (ORFEUS)-SPAS*** payloads were joint DARA (German Space Agency)/NASA missions flown on two shuttle flights. The first flight was September 12-22, 1993 aboard the shuttle Discovery. The second flight, aboard Columbia, was from November 19, through December 7, 1996.



The free-flying ORFEUS-SPAS platform was designed to be deployed and and retreived from the shuttle.

The three instruments on the ORFEUS were designed to provide astronomical ultraviolet spectroscopic observations over the wavelength range from 40 to 140 nanometers. The three instruments were:

- Tübingen Ultraviolet Echelle Spectrometer (TUES); (PI) Prof. Michael Grewing; University of Tübingen
- Berkeley Extreme and Far-UV Spectrometer (BEFS); (PI) Dr. Mark Hurwitz; University of California, Berkeley. This instrument was called the Extreme Ultraviolet (EUV) Spectrometer in the ORFEUS-SPAS II Mission Research Announcement. It was later renamed.
- Interstellar Medium Absorption Profile Spectrograph (IMAPS); (PI) Dr. Edward Jenkins; Princeton University

The largest science instrument onboard was a 1-meter telescope. The telescope primary was coated with iridium to improve its light gathering power in the ultraviolet. Incoming light was focused to a movable mirror which deflected the light rays into the FUV Spectrometer (i.e., TUES), which operated in the 90-140 nanometer range. When the pick-off mirror was moved out of the beam, light fell instead onto the BEFS Spectrometer, which covered wavelengths between 39 and 120 nanometers. A second, separate instrument, the IMAPS Spectrograph, recorded extremely high resolution spectral data in the 95-115 nanometer range.

This information came from the ORFEUS-SPAS II Mission Research Announcement. A postscript version of this research announcement is located in [/archive.stsci.edu/pub/pub/orfeus/orfeus_nra.ps]

Getting Started

The Berkeley Extreme and Far-UV Spectrometer (BEFS), flew on the Orbiting and Retrievable Far and Extreme Ultraviolet Spectrograph (ORFEUS)-SPAS for 5 days in September 1993 and again for 14 days in November 1996.

The first BEFS mission obtained spectra of about 75 objects, and the second mission (BEFS II) obtained spectra of about 102 objects. The BEFS spectrograph's full bandpass is 390 - 1218 Å, but most observations were done in the FUV region (900 - 1250 Å) with a mean spectral resolution of 95 km/s FWHM for point sources.

A table of the BEFS I & II observations by type/spectral class is given below.

Table of BEFS Observations

Type	BEFS I & II
Early Type Stars	87
Coronae/Late Stars	30
White Dwarf	14
Cataclysmic Variable	9
Extragalactic Object	11
Planetary Nebulae	8
Solar System	5
Other	9

Search and Retrieval

BEFS data of interest may be found by searching the MAST BEFS database. As explained in the Search Help page, users may specify search criteria and output format. On the search results page, users may mark datasets of interest to be downloaded as a tar file.

A "quick search" of the BEFS catalog may be performed by entering a target name or coordinates in the form labeled BEFS Target Search at the top of the left navigation menu.

Users may also peruse a "catalog" of BEFS data. Click on the Data ID in the table to bring up a preview plot and some associated information. Click on the grating entry to obtain the other files (including the time-tagged spectral-photon data). The user may find it useful to read an overview of the data file types. To save the data to disk, hold down the SHIFT key while clicking on the link. (This should work for most browsers. Others may require you to click the second or third mouse button instead of the first.) The data are all gzipped. Some browsers may unzip the data. The files are all in FITS format.

BEFS Catalog of Observations

The following catalog lists the objects observed by the Berkeley Extreme and Far_Ultraviolet Spectrometer (BEFS) during both ORFEUS missions. A preview plot of the spectrum may be views by clicking on the Data ID in the table. The user may click on the grating entry to obtain the other files (including the time-tagged spectral-photon data). The user may find it useful to read an overview of the data file types. To save the data to disk, hold down the SHIFT key while clicking on the link. (This should work for most browsers. Others may require you to click the second or third mouse button instead of the first.) The data are all gzipped. Some browsers may unzip the data. The files are all in FITS format.

List all changes for BEFS

More MAST mission data now on-line
2002 February 27
All IUE, UIT, BEFS and VLA-FIRST data are now on-line on a RAID array. The response time for data downloads for these missions should improve significantly. Data for missions HUT, WUPPE, TUES, and Copernicus were already on-line. HST and FUSE data remain on DADS and response times for data download for these two missions are not affected. EUVE data are held at HEASARC and this data is also not affected.

Name Resolver Option Available in Cross Correlation search
2002 January 15
The cross correlation search option available from the top MAST page now allows a choice of NED or SIMBAD for resolving user-specified target names. (The previous version only used SIMBAD.)

New MAST/ADS Data Links
2002 January 11
The ADS data links to data archived winthin MAST have been revised. Now a link to a single MAST page is shown which displays all the known MAST references for a single bibcode. (See 1995ApJ...449..488R as an example.)

New Plotting Option Offered in MAST Scrapbook
2001 October 18
A new option for coplotting multiple spectra and adjusting plot scales is now available in the MAST scrapbook.

New BEFS IDL Programs
2001 August 15
Two new IDL programs are now available for BEFS users: extract_tt.pro is an IDL version of the c program which creates time-tagged spectral-photon lists for any spectrum, and makeair.pro reads an off-axis (SPD2) spectrum and uses the observed airglow lines to scale a synthetic airglow spectrum. See the README file for more information.

BEFS spectra added to Scrapbook
2001 August 1
Representative spectra from the ORFEUS BEFS mission have now been added to the MAST scrapbook.

Change in BEFS Preview Data for eps CMa
2001 July 31
The BEFS preview data for eps CMA which was originally created using data from the D grating has been replaced with data from the B grating when it was discovered that the D grating fluxes were of questionable quality. The affected data sets include: BEFS2093, BEFS2120, BEFS2114, BEFS2143, BEFS2116

BEFS Data Reduction Software
2001 July 23
The BEFS1 and BEFS2 data reduction software is now available. The software is described and accessible from the BEFS Data Analysis/Reduction page.

Data Characteristics Plots Updated
2001 June 13
The MAST Data Characteristics plots have been updated to include the FUSE, TUES, BEFS, and SDSS missions.

Target Search Error
2001 June 12
An error was discovered in the target search available from the main MAST page. Searches would fail for object names containing special characters (such as a "+" symbol as in BD +28 4211). The error was fixed on the above date.

Implementation of Redesigned MAST Web Site
2001 June 4
The MAST redesigned web site is now online. The new dynamically-generated pages feature a common page layout, options for site-wide index searches, mission-specific target name searches, easier site navigation, and a printer-friendly page display option.

BEFS 2 Data now available
2001 May 16
The BEFS data from the second ORFEUS flight (Nov. 19, 1996 - Dec. 7, 1996) is now available.

Customized BEFS preview plots now available
2001 March 6
The BEFS preview pages now offer an interactive plotting option to customize plots of flux versus wavelength using data extracted from the BEFS ASCII table files.

BEFS-1 Literature Links Updated
2001 January 25
The BEFS-1 reference database table entries (and ADS data links) are now complete through year 2000.

BEFS Journal References now available
2000 December 12
A new "Ref" field has been added to the BEFS search results page which lists the number of published papers referencing the particular BEFS data set. Clicking on the number will display the list of references with links to the online ADS papers. The references currently include only papers from the first BEFS mission; the BEFS-II archive has not yet been reviewed.

Improved Wavelengths in BEFS ASCII files
2000 November 27
An error was discovered in the wavelength assignments derived from the expression listed in the BEFS ASCII files. Differences as large as 10 Angstroms (between the ASCII wavelengths and the BEFS .spd1 FITS files) could occur at the short wavelength end of the spectra. New ASCII files have been implemented which replace the wavelength expression with a new column of wavelengths.

Corrections to BEFS ASCII Files of Fluxes and Wavelengths
2000 November 15
An error was discovered in the way fluxes and error estimates were stored in the BEFS ASCII table files. Instead of values being written as two columns of flux1, error1, flux2, error2, ..., the entries were stored as flux1, flux2, flux3, flux4,... error1, error2,... Corrected files are now available. The file creation date listed on the first line of the file can be used to distinguish the old and new files.

Cross Correlations with Sky2000 Catalog
2000 August 16
Cross correlations of MAST missions with the SKYMAP Sky2000 catalog (version 3) are now possible from the MAST Cross Correlation page.

New Copyright Notice
2000 May 12
STScI has adopted a new Copyright statement. Most, if not all, MAST web pages should now include a link to the new page.

BEFS preview spectra online.
1999 November 11
Preview spectra, gzipped ASCII files of flux and wavelength, and display of the BEFS FITS headers are now available from the BEFS search results page.

Catalog search and Data Retrieval now available.
1999 October 13
The BEFS-1 search page is now available. Data can be downloaded from the search results page.

MAST BEFS web site development.
1999 August 11

Frequently Asked Questions

Archive Data

- Where do I get BEFS archival data?

Instruments

- What are the differences between BEFS I and BEFS II?

Archive Data

- ***Where do I get BEFS archival data?***
  Both BEFS I and II data can be obtained by searching the on-line catalog at click here to search the BEFS archive. Or by ftp access (please see the obtaining BEFS data page.

Instruments

- ***What are the differences between BEFS I and BEFS II?***
  For BEFS II, two of the four diffraction grating were overcoated with silicon carbide and the instrument electronics were modified for improved imaging at high count rates. Three apertures were added for spectroscopy: 1) with an on-axis 26" hole, 2) a second clear hole displaced by 2.4' and 1.4 times larger for diffuse sky glow or serendipitous spectroscopy, and 3) a large 2' aperture with a tin filter opaque to FUV radiation, but transparent in the EUV and used primarily for observations of epsilon CMa.

BEFS Data Reduction and Analysis

BEFS data consists of spectroscopic data in FITS format. The FITS spectra contain binary table extensions with both 1st and 2nd order spectra. Please see:

Reading in IDL for information on reading BEFS data with IDL.
Reading in IRAF for information on reading BEFS data with IRAF, and please see
Data Caveats for details about nuances in the data.

Time-tagged spectral-photon lists for any spectrum can be produced using the extract-tt routine. See the Time-Tagged Data page for more information. The extract-tt routine (and other project-provided data analysis software) can be downloaded from the archive.stsci.edu/pub/orfeus/befs/software directory via the web or anonymous ftp.

Instrumentation and Operations

The general design of the Berkeley spectrograph (BEFS) is discussed by Hurwitz & Bowyer (1986), while its calibration and performance on the ORFEUS-SPAS I and II missions are described by Hurwitz & Bowyer (1996) and Hurwitz et al. (1998), respectively

Another description of the instrument was published in

"Bowyer, S., & Hurwitz, M., "ORFEUS-SPAS: The Berkeley EUV Spectrometer" in *Observatories in Earth Orbit and Beyond*, ed. Y. Kondo (Kluwer Academic Publishers), 475-480, 1990

The BEFS final calibration paper:

Dixon, W.V., Dupuis, J., & Hurwitz, M., "Final Calibration of the Berkeley Extreme and Far-Ultraviolet Spectrometer on the ORFEUS-SPAS I and II Missions" will appear in the January, 2002 issue of PASP.

Project Publications

There are over 150 citations to ORFEUS papers and conference proceedings at ADS. Descriptions of the instruments and their performances are listed below.

- **Instrument Description 1986**
- **Instrument Description 1990**
- **ORFEUS 1 Inst. Performance**
- **ORFEUS 2 Inst. Performance**
- Final Calibration for ORFEUS I & II Missions

- NASA's ORFEUS-SPAS II Mission page

Acknowledgments

The MAST staff would like to thank the following groups and individuals for help in making the BEFS data, documentation, and WEB site available to the public:

- BEFS Project members **Mark Hurwitz**, **Stuart Bowyer**, and **Van Dixon** (University of California, Berkeley) for advice, permissions to reprint some documentation and information in general on the BEFS project;
- **Kluwer Academic Publishers**, publishers of "Astrophysics in the Extreme Ultraviolet", for permission to reprint the article "The Berkeley Spectrometer for *ORFEUS*: Laboratory and In-Flight Performance" by Hurwitz and Bowyer (1996,601). Special thanks go to **Berendina Schermers-van Straalen**, Rights and Permissions Manager for Kluwer Academic Publishers.

The ***Berkeley Extreme and Far-UV Spectrometer (BEFS)***, flew on the Orbiting and Retrievable Far and Extreme Ultraviolet Spectrograph (ORFEUS)-SPAS I and II space shuttle missions in 1993 and 1996, returning high-resolution (λ/3000) FUV spectra (900-1200 Å) of 75 astrophysical objects from the first flight and more than 100 from the second. EUV spectra (400-900 Å) were obtained for a subset of these targets.

The **Interstellar Medium Absorption Profile Spectrograph (IMAPS)** obtained high resolution (R=75,000 for IMAPS-1) objective-grating echelle spectra of hot stars, over the spectral region 950-1150 Å. The Principal Investigator was Dr. Edward Jenkins from Princeton University. IMAPS was one of 3 spectrographs comprising the ORFEUS-SPAS mission. The ORFEUS-SPAS platform was deployed from the Space Shuttle Discovery in September, 1993 and from the Space Shuttle Columbia in November, 1996. The IMAPS archive currently contains roughly 600 spectral images of 10 hot stars from the first shuttle flight. Once the proprietary period ends for the second IMAPS mission, the archive will include an additional 3,900 spectral images of 29 stars.

Getting Started

The Tübingen Echelle (TUES) obtained moderate dispersion observations (R=13,000) using an echelle grating including orders 40 - 61 from 910 - 1410 Angstroms. The instrument was designed and built by the University of Tübingen (PI: M. Grewing) and flew as one of three spectrographs on the ORFEUS/SPAS-2 mission for 14 days in November/December 1996. The instrumental resolution was about 10,000 and the effective aperture peaks at 1.3 cm^2 near 1100 Angstroms. Objects were observed in a 10 arcsec entrance aperture. The wavelength calibration was established by means of interstellar molecular hydrogen lines.

The mission observed 62 targets (all stars or planetary nebulae) during a total of 169 hours on target. Most of these observations were of a monitoring nature. The data are fully calibrated and ripple corrections applied, so that merging of data (when overlapping) in adjacent echelle orders is possible.

The search form may be used to select data from the TUES catalog by object name, coordinates, and date of observation. In addition, users may browse the "catalog" or download the image using anonymous ftp. The images are archived as FITS files.

Search and Retrieval

TUES data of interest may be found by searching the MAST TUES database. As explained in the Search Help page, users may specify search criteria and output format. On the search results page, users may mark datasets of interest to be downloaded as a tar file.

A "quick search" of the TUES catalog may be performed by entering a target name or coordinates in the form labeled TUES Target Search at the top of the left navigation menu.

Users may also peruse a "catalog" of TUES data. Click on the object name in the table to bring up a preview plot and some associated information. Click on the data ID entry to obtain the other files. To save the data to disk, hold down the SHIFT key while clicking on the link. (This should work for most browsers. Others may require you to click the second or third mouse button instead of the first.) The data are all gzipped. Some browsers may unzip the data. The files are all in FITS format.

TUES Catalog of Observations

The following catalog lists the objects observed by the TUES during the second ORFEUS missions. A preview plot of the spectrum may be views by clicking on the object name in the table. The user may click on the data ID entry to obtain the other files.

To save the data to disk, hold down the SHIFT key while clicking on the link. (This should work for most browsers. Others may require you to click the second or third mouse button instead of the first.) The data are all gzipped. Some browsers may unzip the data. The files are all in FITS format.

What's New for TUES during last 6 months

More MAST mission data now on-line
2002 February 27
All IUE, UIT, BEFS and VLA-FIRST data are now on-line on a RAID array. The response time for data downloads for these missions should improve significantly. Data for missions HUT, WUPPE, TUES, and Copernicus were already on-line. HST and FUSE data remain on DADS and response times for data download for these two missions are not affected. EUVE data are held at HEASARC and this data is also not affected.

Name Resolver Option Available in Cross Correlation search
2002 January 15
The cross correlation search option available from the top MAST page now allows a choice of NED or SIMBAD for resolving user-specified target names. (The previous version only used SIMBAD.)

New MAST/ADS Data Links
2002 January 11
The ADS data links to data archived winthin MAST have been revised. Now a link to a single MAST page is shown which displays all the known MAST references for a single bibcode. (See 1995ApJ...449..488R as an example.)

New Plotting Option Offered in MAST Scrapbook
2001 October 18
A new option for coplotting multiple spectra and adjusting plot scales is now available in the MAST scrapbook.

Frequently Asked Questions

Data Handling

Data Characteristics

Data Handling

- ***Where can I get TUES archival data?***
  See the obtaining TUES data web page.

- ***Can you explain the TUES file naming conventions?***
  Basically names are of the form TUESnnnn_m_o.fits where the target ID ("nnnn") is a special 4-digit target identification number and the observation number ("m") refers to the order in which the exposures (for a given target) were obtained. A third number ("o") indicates several pointings were obtained during a single observation (sometimes to improve the alignment of the telescope). A "_PH" denotes an integration from single photon events recorded onboard but integrated after the mission. See also the TUES file naming conventions described in the data products page.

Data Characteristics

- ***How accurate are the calibrated flux values?***
  A HST archive model of G191B2B http://garnet.stsci.edu/STIS/models/tables/g191b2b_mod_002.tab" was used as a reference for the absolute flux calibration. The calibration was additionally checked with a model of BD +28°4211 (R.Napiwotzki). We guess an accuracy of ±10% for the flux calibration. This is valid, if the object was fully centered within the diaphragm. There are, however, some observations for which the object was not completely centered. The reasons are probably due to temperature drifts of the telescope causing a shift of the alignment. In some cases also slightly wrong coordinates of the target might have led to a decentralization.

- ***What is the wavelength coverage of the echelle spectra?***
  The Tübingen Echelle (TUES) obtained moderate dispersion observations (R= 13,000) using an echelle grating including orders 40-61 covering the wavelength range from 910 to 1410 Angstroms.

ORFEUS II Echelle Data Reduction

By J. Barnstedt

Contents

---

1. Steps of data processing

A) Extraction

All orders were extracted automatically from the images, i.e. during extraction a centering in y-direction (cross dispersion direction) was applied according to the center of gravity for each individual echelle order. The extraction is done in x-direction (main dispersion direction) by summing up a well defined number of pixels in y-direction. The number of pixels used for extraction in y-direction varies with the echelle order and is indicated in the header of the data file for each echelle order ("cut width"). The center for the extraction in y-direction follows a straight line along each order and is located on whole pixel numbers.

Some echelle images show tilted absorption lines within the strip of the echelle orders. In such cases the extraction was done summing up the pixels tilted by 45 degrees, which results in a significant increase in resolution.

back to table of contents

B) Background

Between the echelle orders a line of 3 pixels width was used to estimate the background. With exception of orders 40, 41 and 42 the background was calculated as average of the strip above and below the corresponding order. For the first three orders only the background values below each order were calculated. The so calculated background was smoothed twice with a width of 21 pixels: First a median filter was applied and as a second step a boxcar smoothing was used. This smoothing works fine if the counts within the background pixels are not too low. For very low counts within the background field other smoothing methods might be more satisfying.

Within very broad absorption lines (e.g. Ly-alpha) the background subtracted is in general overestimated. The reason might be that by far the strongest contribution to the background comes from stray light of the echelle grating:
This stray light is scattered exactly in horizontal direction on the detector while the echelle orders run slightly tilted across the detector. So within very broad absorption lines stray light is reduced within the echelle orders, and almost normal in the background extraction fields.

back to table of contents

C) Pixels 511/512

Due to arithmetic rounding errors at the calculation of the photon position within the echelle electronics an artefact is observed, especially in the middle of the detector image, which leads to a higher intensity in one of these two pixels while the other shows a corresponding loss of intensity. This means, that the pixel border between these two pixels seems to be somewhat shifted. This effect is eliminated by applying an averaging to these two pixels.

back to table of contents

D) Correction of the blaze function

The efficiency of echelle gratings has a maximum for one direction of diffraction (blaze angle), while the efficiency is reduced as a function of the deviation from this angle of diffraction (blaze function). The optimized diffraction direction was pre flight adjusted to point to the center of the echelle detector. What we find now is that the center of maximum efficiency is different for each echelle order. Furthermore we found that both the position and the width of the blaze function differ from observation to observation.

Therefore it was neccessary to introduce an individual blaze correction for each observation. Often only the overlap region between two adjacent orders could be used as a criterion for a good blaze correction.

back to table of contents

E) Wavelength calibration

The wavelength calibration was calculated from the positions of 814 interstellar absorption lines from 12 different echelle images. Using these data we determined the parameters for the dispersion function. Radial velocity values were not used for the calibration, the zero position of the dispersion function was determined seperately. The accuracy is better than ±0.005nm, i.e. better than the optical resolution of the instrument.

We used the position of the Ly-alpha geocoronal emission line as a reference for the absolute wavelength zero position. We found that for different observation blocks the position of the Ly-alpha line differed up to 0.006 nm. For this a wavelength correction for each observation block was applied.

Further wavelength corrections are:

a. Heliocentric radial velocity correction
b. Radial velocity correction due to the satellite's orbital velocity.

The given extractions use the on board integrated images, for these images only the average of the orbital velocity component during the observation was used for correction. In future we will extract the spectra of the individually registered photons for which the orbital radial velocity correction will be applied to each individual photon.

An additional wavelength error might occur, if the target was not exactly centered within the 20" diaphragm. The maximum resulting uncertainty is $\pm 1.2\ 10^{-4}$ as a relative wavelength error. This error was not corrected up to now.

To overcome this problem we will try to get a hint about the image position within the diaphragm from the count rates. Rapidly changing count rates indicate that the image was close to the edge of the diaphragm. In these cases, we can correlate the ASTRO-SPAS pointing data with the count rate fluctuations and thus find out the x/y-coordinates of the image in the diaphragm. Anyway this correction procedure will be complicated and tedious.

back to table of contents

F) Correction of loss of sensitivity in the detector edges

The corners of the detector image and the left edge show a loss of sensitivity which is probably due to a reduced efficiency of the repeller grid in front of the detector. The electrical field in front of the MCPs (about 50V/mm) is used to force those photo electrons back into the MCP channels, which are released from the areas in between the channels. This improves the quantum efficiency by about 30% (causing also a loss of 10% due to shading of the grid in front of the detector). Probably due to an inhomogenious field at the borders of the detector the efficiency of the repeller field is reduced, and there is a rather sharp step visible between lower and normal sensitivity. This is visible in some images as a circular shaped area. We estimated a loss of about 25% and corrected this by applying a "smooth" step function. The position, width and height of the step was estimated for each order from the sum of all echelle measurements. The actually used correction values are listed in the column "EDGE_CORR" (see below).

A detailed flat field correction was not applied. The reason is, that the optical light path of the spectrometer cannot be reproduced in our laboratory. This however would be essential for an exact estimation of the flat field behavior of the detector. Any other correction methods are too uncertain to be useful.

back to table of contents

G) Absolute flux calibration

We used a HST archive model of G191B2B "http://garnet.stsci.edu/STIS/models/tables/g191b2b_mod_002.tab" as a reference for the absolute flux calibration. The calibration was additionally checked with a model of BD +28°4211 (R.Napiwotzki). We guess an accuracy of ±10% for the flux calibration. This is valid, if the object was fully centered within the diaphragm. There are, however, some observations for which the object was not completely centered. The reasons are probably some temperature drifts of the telescope causing a shift of the alignment. In some cases also slightly wrong coordinates of the target might have led to a decentralization.

Observations with badly centered targets are identified by their strongly varying count rates. The flux calibration was calculated for the maximum observed count rate for the corresponding target (also from other observations of this target, if neccessary). This count rate was scaled with the registered count rate in the integrated image. The corresponding count rates are documented within the file headers.

The file headers contain a maximum count rate and an actual (average) count rate of the lower electronic threshold. The third value is the registered count rate in the actual image. The actual count rate of the lower threshold and the registered count rate differ for the following reasons:

a. The electronic upper threshold suppresses pulses too large to be processed.
b. Electronic dead time effects and dead time effects from the on board processor reduce the electronic efficiency.

The above page was written by Jürgen Barnstedt from the ORFEUS Group at Tübingen and is reproduced here for the MAST archive with his permission.

Instrumentation and Operations

The general design of the TUebingen Echelle Spectrograph (TUES) was discussed by Grewing et al. (1991; in Extreme Ultraviolet Astronomy, ed. R. Malina & S. Bowyer, p. 422), and a general review of the instrument and mission can be found in Appenzeller et al. (1998, in Ultraviolet Astrophysics: Beyond the Final IUE Archive, ed. W. Wamsteker & R. Gonzalez-Riestra, p. 757).

A summary of the in-flight and calibration results is given by Barnstedt et al. (1999). Wavelength calibration results from interstellar molecular lines are reported in Barnstedt et al. (2000).

Descriptions can be found in the Tuebingen project's home websites of the

- ORFEUS telescope/spectrograph
- echelle spectrograph
- detector

The TUES was deployed as part of the ORFEUS/SPAS-2 platform by the Columbia Space Shuttle on November 19, 1996, and operated for 14 days of the Shuttle's 17-day mission (STS-80). Once deployed, ORFEUS conducted program observations by receiving real-time ground commands from Drs. Ron Polidan, Richard Miller, and Peter Vedder at the Kennedy Spacecraft Center Operations & Control Center.

The ***Tübingen Echelle Spectrograph (TUES)***, designed and managed at the University of Tübingen, flew on the Orbiting and Retrievable Far and Extreme Ultraviolet Spectrograph (ORFEUS)-SPAS II space shuttle mission in 1996, returning spectra in the 900 Å to 1400 Å wavelength range. The instrument was designed to achieve a spectral resolution of $\lambda/\Delta\lambda$=10000 when used with an entrance aperture of 10" diameter. During the 17.7 day flight, TUES returned 239 spectra of 62 targets.

Getting Started

The Digitized Sky Survey (DSS) is a ground-based imaging survey of the entire sky in several colors. The survey, performed with Palomar and UK Schmidt telescopes, produced photographic plates that were later digitized at STScI to produce the Hubble Guide Stars Catalog (GSC).

Each plate produced by the Survey covers 6.5 x 6.5 degrees of the sky, and the plates have been digitized using a modified PDS microdensitometer. The digital images have a pixel size of either 25 microns (1.7 arcsec per pixel) or 15 microns (1.0 arcsec per pixel), and are 14000 x 14000 or 23040 x 23040 npixels perl side. The images are stored on 12-inch optical media and are difficult to access quickly.

In order to provide convenient access to this valuable resource, the images have been compressed using a technique based on the H-transform to reduce the data volume. Although the technique is lossy, it is adaptive so that it preserves the signal very well. We typically compress the data by a factor of 10 but much higher compression ratios are possible. These compressed data are then written to CDROM which are then placed into jukeboxes for rapid access. Users can then easily retrieve image data for any part of the sky.

DSS images may be retrieved through the Web. To retrieve an image, you supply either a position (RA and Dec) or a target name, for which the position will be looked up in either the SIMBAD or NED online databases. You also specify the format and size of the image and the survey from which to extract, and the image will be delivered directly back though your browser. There is also an interface that will show you which plates your image could be extracted from, and allows you to select images from a particular plate.

Images are also accessible through StarView, and other interfaces such as the Visual Target Tuner (VTT), Aladin, and xephem access online versions of the DSS. The DSS is also available through the web from other web sites as well as at STScI.

Some information is available at this site for computing astrometry and photometry of DSS images.

List all changes for DSS

More MAST mission data now on-line
2002 February 27
All IUE, UIT, BEFS and VLA-FIRST data are now on-line on a RAID array. The response time for data downloads for these missions should improve significantly. Data for missions HUT, WUPPE, TUES, and Copernicus were already on-line. HST and FUSE data remain on DADS and response times for data download for these two missions are not affected. EUVE data are held at HEASARC and this data is also not affected.

Name Resolver Option Available in Cross Correlation search
2002 January 15
The cross correlation search option available from the top MAST page now allows a choice of NED or SIMBAD for resolving user-specified target names. (The previous version only used SIMBAD.)

New MAST/ADS Data Links
2002 January 11
The ADS data links to data archived winthin MAST have been revised. Now a link to a single MAST page is shown which displays all the known MAST references for a single bibcode. (See 1995ApJ...449..488R as an example.)

New Plotting Option Offered in MAST Scrapbook
2001 October 18
A new option for coplotting multiple spectra and adjusting plot scales is now available in the MAST scrapbook.

Data Characteristics Plots Updated
2001 June 13
The MAST Data Characteristics plots have been updated to include the FUSE, TUES, BEFS, and SDSS missions.

Target Search Error
2001 June 12
An error was discovered in the target search available from the main MAST page. Searches would fail for object names containing special characters (such as a "+" symbol as in BD +28 4211). The error was fixed on the above date.

Implementation of Redesigned MAST Web Site
2001 June 4
The MAST redesigned web site is now online. The new dynamically-generated pages feature a common page layout, options for site-wide index searches, mission-specific target name searches, easier site navigation, and a printer-friendly page display option.

Cross Correlations with Sky2000 Catalog
2000 August 16
Cross correlations of MAST missions with the SKYMAP Sky2000 catalog (version 3) are now possible from the MAST Cross Correlation page.

DSS CD Drive Replaced
2000 July 18
One of the 6 CD drives used to retrieve DSS images has been replaced and appears to have fixed most of the recent problems with downloading DSS files. A second drive is scheduled to be replaced next week.

New Copyright Notice
2000 May 12
STScI has adopted a new Copyright statement. Most, if not all, MAST web pages should now include a link to the new page.

DSS Plate Finder
1999 February 15
Using the Plate Finder, you can see all the plates available for a given position, and extract from them individually. You can also get a schematic map of the plate, with astronomical object & archive catalogs overplotted.

New DSS CDROM Jukebox
1998 November 6
We have replaced our 3.5 year old CDROM jukebox with a newer, faster model. Retrievals should be running a lot faster now.

New DSS Pages
1998 June 24
The DSS pages are being restructured to reflect the style used in the other MAST missions. The old retrieval form will still be available, but we will also be adding new forms and informational pages in the coming months.

SIMBAD Mirror at CfA
1998 June 24
Our SIMBAD name resolver is now using the Astrophysics Data System's new SIMBAD Mirror at the Center for Astrophysics (CfA) at Harvard. We used to go to the main SIMBAD server in Strasbourg, France, but the CfA mirror should be a lot faster (because of the faster network connection between Baltimore and Boston).

Busy Server
1998 June 24
As use of the DSS service increases, more users are getting messages that the jukebox is busy. We're ordering a faster jukebox and web server to acoomodate the increasing load.

Frequently Asked Questions

Web Access

Exposure and Survey

Image Anomalies

Using Images

Web Access

- ***Is there a way to retrieve DSS images in batches?***
  No. We know this would be a convenient service, and we would like to do it, but our jukebox is currently getting over 1500 hits a day (more like a thousand, if you count internal accesses and accesses to the Medium Deep Survey), and potential abuse of a batch service could easily put the jukebox into a perpetually busy state, denying the DSS to everyone.

- ***What are SIMBAD & NED?***
  SIMBAD (in Strasbourg, France) and NED (in Pasadena, California) are centralized astronomical databases that provide services like taking an object name and returning its coordinates. That's how they're used here: to redraw the DSS form with your object's RA and Dec in place, so you don't have to go look them up.

  Note: SIMBAD and NED only catalog fixed objects, like stars and galaxies. These databases don't track moving targets, like planets, comets, and asteroids. The Sky Surveys were designed to avoid bright solar-system objects anyway, so there won't be any images in the DSS of Saturn or Comet Hale-Bopp.

  Also, remember that NED only catalogs objects outside our own galaxy, like external galaxies, quasars, etc. NED doesn't catalog individual stars or nebulae.

  (For you acronym fans, SIMBAD stands for **S**et of **I**dentifications, **M**easurements, and **B**ibliography for **A**stronomical **D**ata; NED stands for **N**asa **E**xtragalactic **D**atabase.)

- ***I tried to use SIMBAD, but it never came back.***
  SIMBAD is a wonderful service, but unfortunately, the network connection between Baltimore and Strasbourg isn't the best it could be. Sometimes, the network hangs; other times, SIMBAD is just too busy to answer right away.

  If you're looking for extragalactic objects, and SIMBAD isn't working, try NED. Ned is in California, and our network connection is a bit better there.

- ***Are there other sites that offer DSS services?***
  Yes, there are. Here's a partial list.

Exposure and Survey

- ***How can I tell what telescope/filter was used for a given image?***
  The data are either from the UK Schmidt or the Oschin Schmidt (Palomar) telescopes. You can tell which survey the data come from by looking at the `REGION` keyword in the FITS header. You can also get the observatory ID from the header keyword `TELESCOP`.

  For the First Generation DSS, the emulsion/filter combinations are:

  - `XE` - POSS-E RED PLATE,
  - `XV` - SERC-V Equatorial extension,
  - `S` - SERC-J Survey

  (Also, see below about the short-exposure plates near M31 and the Magellanic Clouds.)

  For the Second Generation, these are:

  - `ER` - 'Equatorial Red' survey (UK Schmidt) IIIaF + RG610
  - `XS` - 'Second Epoch Southern' survey (UK Schmidt) IIIaF + RG610
  - `GR` - 'Galactic Red' survey (UK Schmidt) IIIaF + RG610 SHORT exposure in galactic plane
  - `XP` - POSS-II Red IIIaF + RG610
  - `XJ` - POSS-II Blue IIIaJ + GG385
  - `XF` - POSS-II Near-IR IVN + RG9

  (To get information about individual images, you'll need to get them in FITS format and look at the header. This information is not preserved in the GIF image.)

- ***What do the pixel values represent?***
  Scans in the DSS are digitizations of photographic plates. The pixel values in the scans are a measure of the photographic density of the original plate, which is non-linear with the intensity.

- ***Is a photometric calibration available?***
  Yes. The Catalogs and Surveys Branch (originators of the Digitized Sky Survey and the Guide Star Catalog) recently completed a photometric calibration for the First Generation survey (northern POSS-E, southern SERC-J, and southern Galactic Plane SERC-V).

  (There was a crude calibration done on the *southern* SERC plates; see Lasker, B., et al. 1990 AJ, 99, 2019. Equation 1 shows this solution. Table V lists coefficients for Palomar, too, but *don't use them!* They were for a Mini-J survey, not the actual POSS.)

- ***How about the exposure time?***
  That's in the `EXPOSURE` keyword in the FITS header. (Note that the exposure time there is in minutes.) All exposures are between 2400 and 4200 seconds.

- ***What's the plate scale?***
  For the First Generation scans, the plate scale is 1.7 arcsec per pixel; for the Second Generation scans, it's 1.0 arcsec per pixel. (The plate scale is derivable from the FITS keywords `PLTSCALE` and `XPIXELSZ` / `YPIXELSZ`).

- ***What Second-Generation survey plates are currently available?***
  A complete list of the plates currently available for the Second Generation survey is available at http://archive.stsci.edu/cgi-bin/dss2list.

Image Anomalies

- ***What's this funny line/feature/UFO in my scan?***
  These images were scanned from photographic plates, so every once in a while, you will encounter a scratch, internal telescope reflection, fingerprint, etc. in your image. So far, none have turned out to be aliens. I'm compiling an informal catalog of regions with plate anomalies, so if you run across one, let us know.

- ***I have a field near M31 that I know should have a lot of stars in it, but I only see a few.***
  This field was probably drawn from the special short-exposure plate of M31.

  There are three such plates, for the Large Magellenic Cloud, the Small Magellenic Cloud, and M31, exposed for 5 minutes instead of the usual 50 or so:

  - `XX001` - The Large Magellanic Cloud
  - `XX002` - The Small Magellanic Cloud
  - `XX005` - M31 (Andromeda Galaxy)

  These plates are in the V band; specifically, they were taken with IIaD emulsion and GG 495 filter.

  The Quick V version may look better; you can access it through the Phase II proposal preparation form.

- ***I tried to get an image of the Orion Nebula, but all I got was a big white spot!***
  It worked; you just need to extract a wider image to see it. The Orion Nebula is so big that all a 15'x15' extraction shows you is the very center, which in these scans *is* a big white spot. Go to a bigger scan size (if you don't mind handling the correspondingly bigger image file).

Using Images

- ***If I use the DSS in my published research, do I need to acknowledge it?***
  We request that you do. The Catalogs & Surveys Branch (CASB) has a recommended acknowledgment.

- ***Can I use images from the DSS in a CD-ROM or some software that I'm writing?***

If you're using images from the DSS for research, teaching purposes and other non-profit activities, you may use them freely, and we only request that you acknowledge the source. Commercial applications require a license. For information about licensing, contact the STScI Business Office:

Contract & Business Services
Space Telescope Science Institute
3700 San Martin Drive
Baltimore MD 21218

http://archive.stsci.edu/dss/

The **Digitized Sky Survey** comprises a set of all-sky photographic surveys in E, V, J, R, and N bands conducted with the Palomar and UK Schmidt telescopes. The Catalogs and Surveys Branch (CASB) is digitizing the photographic plates to support HST observing programs but also as a service to the astronomical community.

The 6.5-degree x 6.5-degree plates are scanned using a modified PDS microdensitometer to a pixel scale of about 1.7 arcseconds per pixel for the POSS, SERC, and Palomar Quick-V surveys, and to about 1.0 arcseconds per pixel for the POSS-II surveys.

Images of any part of the sky may be extracted from the DSS, in either FITS or GIF format.

Getting Started

Introduction

The Catalogs and Surveys Branch (CASB) of the Space Telescope Science Institute (STScI) digitized the photographic Sky survey plates from the Palomar and UK Schmidt telescopes to produce both the Digitized Sky Survey (DSS), and the Guide Star Catalogs (GSC). The catalogs support ground and space-based telescope operations and provide a valuable scientific resource to the astronomical community.

GSC-I was constructed primarily to support the operational requirements of the Hubble Space Telescope for off-axis guide stars. Production scanning began in 1985 and continued through 1988. Catalog construction was performed in parallel with the scanning. It proceeded in stages as production software became available, first for sky-following and object inventory, and later for classification plus photometric and astrometric calibrations. GSC-I contains approximately 19 million stars and other objects in the sixth to fifteenth magnitude range.

GSC-II will obtain proper motion and color information in addition to accurate coordinates, magnitudes and classifications for all objects down to at least 18th magnitude. The all-sky, magnitude-limited Telescope Operations version, GSC2.2, contains positions, classifications, and magnitudes for nearly a half billion objects, and is now available.

See the CASB home page for the latest news and developments. See also the CASB pages on:

What's New for GSC during last 6 months

More MAST mission data now on-line
2002 February 27

All IUE, UIT, BEFS and VLA-FIRST data are now on-line on a RAID array. The response time for data downloads for these missions should improve significantly. Data for missions HUT, WUPPE, TUES, and Copernicus were already on-line. HST and FUSE data remain on DADS and response times for data download for these two missions are not affected. EUVE data are held at HEASARC and this data is also not affected.

Name Resolver Option Available in Cross Correlation search
2002 January 15

The cross correlation search option available from the top MAST page now allows a choice of NED or SIMBAD for resolving user-specified target names. (The previous version only used SIMBAD.)

New MAST/ADS Data Links
2002 January 11

The ADS data links to data archived winthin MAST have been revised. Now a link to a single MAST page is shown which displays all the known MAST references for a single bibcode. (See 1995ApJ...449..488R as an example.)

New Plotting Option Offered in MAST Scrapbook
2001 October 18

A new option for coplotting multiple spectra and adjusting plot scales is now available in the MAST scrapbook.

Frequently Asked Questions

GSC I and II

GSPC

GSC I and II

- ***How were the Guide Star Catalogs created?***
  The basic steps involved include:
  - scanning and digitizing the Schmidt plate material,
  - image processing,
  - calibration for astrometry, photometry, and object classification,
  - Comparison to external catalogs

- ***What is the difference between GSC-I and GSC-II?***
  For a quick summary of the properties of these two catalogs see: http://www-gsss.stsci.edu/gsc/gsc2/CatalogProperites/GSCIIProperties.htm

  The GSC I catalog (version 1.0) was constructed to support pointing and target aquistion for the HST. The catalog contains approximately 19 million stars and other objects in the sixth to fifteenth magnitude range, primarily derived from an all-sky, single epoch collection of 6.4 degree by 6.4 degree Schmidt plates. The Schmidt plates for north of +6 degrees consists of a 1982-1984 epoch "Quick V" survey (IIaD, 20 minute exposure) obtained from the Palomar Observatory. The southern fields consist 0f 50-75 minute exposure IIIa-J Schmidt plates, from the UK SERC J/EJ survey (epoch 1975-1988) and a supplemental 4 minute IIa-D southern Galactic plane extension (epoch approximately 1988).

  For more information on the Schmidt plates used to construct the GSC I catalog see: http://www-gsss.stsci.edu/PlateMaterial/plateMaterial.htm

  GSC 1.1 is the catalog used for control and target acquistion for the HST. The improved catalog corrected a number of known problems in the GSC 1.0. The corrected defects included spurious entries (principally due to false detections on the diffraction spikes of bright objects), grossly incorrect entries for the brighter stars (V<7) that were produced from heavily over-exposed Schmidt images, and different entries for the same object having more than one image because of blend-resolution difficulties, as well as astrometric errors at the plate edges.

  GSC 1.2 An astrometric re-calibration of the GSC 1.1 reducing the systematic errors present in the GSC 1.1 positions. This catalog has not been been installed on the HST Guide Star Selection system, so it must not be used for HST observation planning.

  The GSC II will be an all-sky catalog based Schmidt plates at two epochs and three bandpasses, from the Palomar (POSS I and POSS II) and UK Schmidt telescopes (SERC/UK surveys). This catalog will contain postions, magnitudes, colors and proper motions for all objects to at least 18.5 in photographic F. The construction of the GSC II is in progress. A preliminary catalog, GSC 2.2 is now available.

  The GSC2.2 is an all-sky, magnitude-selected subset of this data that has been extracted to support telescope operations at the GEMINI and VLT telescopes. This Telescope Operations version contains positions, classifications, and magnitudes for 435,457,355 objects. The magnitude limits (18.5 in photographic F and 19.5 in photographic J) were implemented to ensure the photometric quality of the released data. Since bright objects are extremely overexposed on the Schmidt plates, positions from the Tycho-2 catalog were used.

  The final version (GSC 2.3), expected to be released in 2002, will also contain proper motions.

  For more information on the Schmidt plates used to construction the GSC I catalog see: http://www-gsss.stsci.edu/PlateMaterial/plateMaterial.htm

- ***When would one use GSC-I instead of GSC-II?***
  GSC-II has not been installed in HST Guide Star Selection system, so it should not be used for HST observation planning.

- ***What material is the GSC II based on?***
  See http://www-gsss.stsci.edu/PlateMaterial/plateMaterial.htm#GSCIIPlates

- ***What reference frame is used for the GSC II catalog?***
  The International Celestial Reference Frame (ICRF).

- ***What magnitude system is used with GSC II?***
  The magnitudes are in the natural system of the photographic plates. See http://www-gsss.stsci.edu/gsc/PlateMaterial/plateMaterial.htm for bandpass information.

- ***How were the positions, magnitudes, and classification selected for objects imaged on more than one plate ?***
  Although the database from which the catalog was constructed contains multiple epochs and observations for a given source, the GSC 2.2.0 exported catalog positions, magnitudes, and classifications for each unique source were selected by the following criteria:

  Positions and magnitudes from plate observations were selected by choosing the observation which occurs closest to the plate center prioritized by bandpass F,J,V, and N respectively. Magnitude cutoffs were applied (F=18.5, J=19.5, V=19.5). If the observation occurred at different plate scanning resolutions, the highest resolution (15 um pixels) was selected over the lower resolution (25 um pixels) for each bandpass regardless of plate location. Classifications were assigned by voting observations into star (0) or nonstar(3) codes.

  For more details see: http://www-gsss.stsci.edu/gsc/gsc2/gsc22_release_notes.htm

- ***What epoch was used for positions?***
  The positions are at the epoch from the plate that they were taken from. We did not take an average or combine in any way the positions imaged on more than one plate. The positions were selected by choosing the observation which occurs closet to the plate center prioritized by bandpass F, J, V, and N repectively.

- ***How were positions determined for bright stars?***
  Since bright objects are extremely overexposed on the Schmidt plates, positions obtained from the Tycho-2 catalog were used (see http://www.astro.ku.dk/%7Eerik/Tycho-2/).

- ***Can you provide the photometric transmission curves ?***
  Yes, here (http://www-gsss.stsci.edu/DSS/Transmission%20Curves/transmission_curves.HTML)

GSPC

- ***What is the GSPC?***
  To support the photometric calibration of the Guide Star catalogs, CASB produced the Guide Star Photometric Catalog. GSPC I is an all-sky set of photoelectrically determined BV sequences in the magnitude range from 9 to 15, generally near the centers of the fields of the GSC-I plates. The GSPC II, a joint project between CASB and Osservatorio Astronomico di Torino, is generally an extension of GSPC I sequences to V=19 in B, V, and R passbands based on CCD photometry.

  For more detailed information see: http://www-gsss.stsci.edu/gspc/GSPChome.htm

- ***What is the sky coverage of the GSPC II?***
  http://www-gsss.stsci.edu/gspc/gspc2_coverage_map.htm

- ***How do I obtain the GSPC data?***
  http://www-gsss.stsci.edu/support/data_access.htm#table

The Guide Star Catalogs were created by the staff of the Catalogs and Surveys Branch of the Space Telescope Science Institute.

The **Guide Star Catalog I** (GSC I) is an all-sky optical catalog of positions and magnitudes of approximately 19 million stars and other objects in the 6th to 15th magnitude range. GSC I catalog is used for the control and target acquistion of the Hubble Space Telesope. The **Guide Star Catalog II** (GSC II) is currently in production and will soon be released to the public. The GSC II is an all-sky catalog of approximately 2 billion stars and galaxies containing positions, magnitudes,colors and proper motions complete to a minimum of V =18.

The **Guide Star Photometric Catalog** (GSPC-I) is an all-sky set of photoelectrically determined BV sequences in the magnitude range from 9 to 15, generally near the centers of the fields of the GSC-I plates. GSPC II is currently in production and will soon be released to the public. GSPC II is generally an extension of GSPC I sequences to V=19 in (B), V and R passbands based on CCD photometry. Its purpose is calibration of the GSC-II. New northern sequences are being added to support the POSS-II.

GSC 2.2 now available!.

Sign-up for the SDSS User's Group and User's Forum

A. Sign-up for User's Group
This list will have announcements regarding scheduled archive downtime, required software upgrades, updated documentation availability. This list is not for general posting; *only the list owner can post to this list*. This list is the most important list for SDSS users to join, since it will provide our only means of keeping the users current with software changes and other time-critical information.

B. Sign-up for User's Forum
Anyone interested in the SDSS may post to this list regarding science, data, analysis, software and any other issues. This list is an open forum list, with discussion regarding scientific issues and other issues of interest to the SDSS community.

Both of these lists are standard LISTSERV mailing lists , with the usual listserver conventions of subscription, unsubscription, and posting.

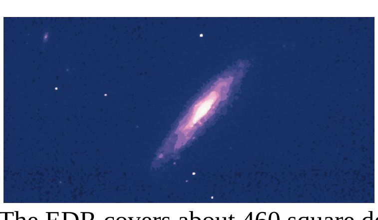
Welcome to the Sloan Digital Sky Survey Archive!



The **Sloan Digital Sky Survey** (SDSS) is using a dedicated 2.5 m telescope and a large format CCD camera to obtain images of over 10,000 square degrees of high Galactic latitude sky in five broad bands (u', g', r', i' and z', centered at 3540, 4770, 6230, 7630, and 9130 Å, respectively). Medium resolution spectra will be obtained for approximately 10^6 galaxies and 100,000 quasars. The early data release (EDR), on June 2001, includes searchable catalogs of images and spectra, images for display and scientific purpose in both 2-D FITS and JPEG formats, and spectra in both 1-D FITS and GIF formats. The EDR covers about 460 square degrees of sky. The next data releases will occur every 18 months or so.

Want to hear more? Sign up for one or both of our users' groups for the latest updates. All regular SDSS users must sign up for the Users' Group, or risk missing critical software and documentation updates.

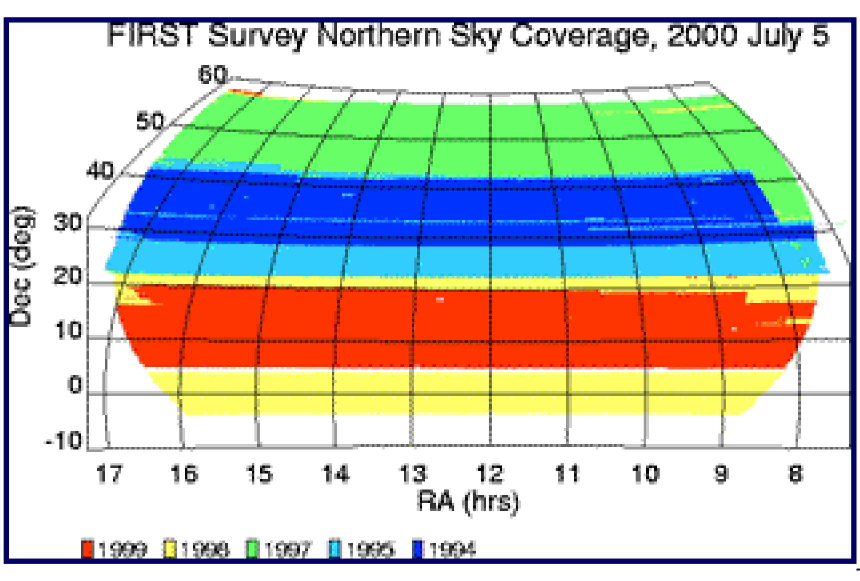
Faint Images of the Radio Sky at Twenty-cm **(FIRST)** is a systematic survey of the North and South Galactic caps begun in 1993, using the **NRAO** Very Large Array **(VLA)** . Typical images are comprised of 1150x1550 1.8" pixels with 5" resolution. Source catalogs are also available including peak and integrated flux densities generated from the high resolution coadded images. The survey yields very accurate (<1 arcsec rms) radio positions of faint (>1 mJy/beam) compact sources. The areas observed were chosen to coincide with the Sloan Digital Sky Survey. For more information, see the **VLA FIRST Web Site**.



Getting Started

ROSAT, the ROentgen SATellite, was an X-ray observatory developed through a cooperative program between Germany, the United States, and the United Kingdom. The satellite was designed and operated by Germany, and was launched by the United States on June 1, 1990. It was turned off on February 12, 1999. The scientific payload consisted of two coaligned experiments, the X-Ray Telescope, used in conjunction with one of the two focal plane instruments, the Position Sensitive Proportional Counter and the High Resolution Imager (covering the 0.1 - 2.4 keV energy range), and the Wide Field Camera (an EUV telescope), which had its own mirror system.

The ROSAT interface at MAST provides access to the ROSAT Master observations log (ROSMASTER) at the High Energy Astrophysics Science Archive Research Center (HEASARC) as a service to our optical/UV community. The MAST ROSAT interface is in fact very similar to the other MAST interfaces, so MAST users should find it easier to access the ROSAT archive through this channel.

The ROSAT Master observations log can be searched on a variety of parameters, ranging from position and object name to exposure time and PI name. Selected data can then be retrieved. Various data products are available, and we recommend our users to check the HEASARC Data Products page for detailed information.

In short, data products include: proposal abstracts (ABSTRACTS), basic products (BASIC: namely FITS files which allow one to extract images, light curves, and spectra using appropriate software [see below]), calibration files (CALIBRATION: response matrices, etc.), and images in GIF format in different bands (GIF IMAGES).

We recommend users using this interface to consult the ROSAT Guest Observer Facility page at HEASARC. There they will be able to find information about:

- the ROSAT mission;
- data analysis documentation and software;
- the ROSAT archive.

Please e-mail any question about ROSAT to rosathelp@athena.gsfc.nasa.gov. Comments about the ROSAT MAST interface should be sent to archive@stsci.edu.

Search and Retrieval

ROSAT data reside at HEASARC but may be accessed electronically through either MAST or HEASARC retrieval sites. The MAST **ROSAT search form** has the same layout and similar query parameters as search forms of other MAST missions. Submission of this form initiates a query to the HEASARC "W3browse" master catalog of ROSAT observations (ROSMASTER), which includes data taken from the Position Sensitive Proportional Counter (PSPC) and High Resolution Imager (HRS) as well as the ROSAT All Sky Survey (RASS). Search help may be consulted for aid in using the search form. We also also provide help in understanding the query syntax transmitted to HEASARC.

Once the requested files are located, they are written to a data distribution disk area on the system, bundled into a tar or zip format file, and downloaded to the disk area specified by the user in the "save as.." pop-up window. The files are downloaded when the pop-up window disappears.

If you have problems retrieving your data, you can contact the help desk via the link at the bottom of this page.

- U.S. ROSAT Guest Observer Facility at HEASARC.
- SAO ROSAT Science Data Center.
- ROSAT at MPE.

We gratefully acknowledge the High Energy Astrophysics Science Archive Research Center (HEASARC) at Goddard Space Flight Center for allowing access to the ROSAT archive. The **ROSAT interface at MAST** provides access to the ROSAT Master observations log (ROSMASTER) at HEASARC as a service to our optical/UV community. The interface is in fact very similar to the other MAST interfaces, so MAST users should find it easier to access the ROSAT archive through this channel.

We recommend that users consult the ROSAT Guest Observer Facility page at HEASARC. There they will be able to find information about:

- the ROSAT mission;
- data analysis documentation and software;
- the ROSAT archive.

Please e-mail any question about ROSAT to rosathelp@athena.gsfc.nasa.gov. Comments about the ROSAT MAST interface should be sent to archive@stsci.edu.

http://archive.stsci.edu/rosat/

ROSAT,**the ROntgen SATellite**, was an X-ray observatory developed through a cooperative program between Germany, the United States, and the United Kingdom. The satellite was designed and operated by Germany, and was launched by the United States on June 1, 1990. It was turned off on February 12, 1999. The ROSAT mission began with a 6-month, all sky Position Sensitive Proportional Counter (PSPC) survey, after which the satellite began a series of pointed observations that continued for the duration of the project.

ROSAT data is maintained and archived at HEASARC. Except for the search and acknowledgments pages, all images and linked pages above are provided by HEASARC.

Process Information: Scrapbook

The MAST Scrapbook is composed of three components: database tables of representative observations from MAST missions, query/search and display software, and thumbnails of spectral plots and images for display. The core element is the two database tables known as the "Table of Representative Spectra" (TORS) and the Table of Representative Images (TORI). The TORS/TORI catalogs contain entries of representative observations for most targets and instrument/mission combinations available in the MAST archives. The construction of these tables and the other components of the MAST scrapbook are described below.

Construction of the TORS/TORI Tables

The detailed selection of the representative observations to be included in the TORS/TORI catalogs varied with each instrument. Prior to the observation selection process, a set of "rules" or specifications were developed for the selection of "the" representative dataset of a multiply observed target in an automated and unbiased way. The specifications included parameters such as exposure lengths and dates of observations. For most missions, the observation choosen for a given grating/wavelength configuration was based on the maximum exposure time, and, to provide the broadest wavelength coverage, the lowest dispersion. For images, observations were selected for a given position on the sky based solely on exposure time.

The specifications for selecting the representative spectral observations are available for each of the following scrapbook missions:

- HST/FOS,
- HST/GHRS,
- HST/STIS,
- Astro/HUT,
- IUE,
- EUVE, and
- ORFEUS/TUES.
- ORFEUS/BEFS.

The specfications for the imaging missions included in the scrapbook are:

- HST/WFPC2
- HST/FOC
- Astro/UIT

Software to select representative spectra from the archives was written for each mission. A preliminary list of unique targets was first created and used as input to the selection software. The software queried the associated instrument database to obtain a list of all candidate observations, then used the specification rules to determine the "representative" observation. The selected observations were then ingested into the TORS/TORI catalogs.

In practice, the determination of entries for the TORS required subjective judgment whenever there was a possibility of target confusion, such as for close binaries, dense clusters, or uncertain optical identifications of UV_bright sources. Another potential source of confusion were extended objects such as resolved galaxies or nebulae, for which observations of a central region have been identified in SIMBAD or NED. Thus, for a supernova remnant filament, a representative observation was likely to be represented by the brightest knot within the extended structure. (The reader should recall that entrance apertures of various spectrographs will subtend different areas on the sky. Thus, spectra of multiple or extended targets from different instruments sometimes do not refer to the same source.) In cases of target confusion, a MAST astronomer compared the spectrum with the description of the object listed in the original proposal, published literature, and/or the spectral type, magnitude, and position given by SIMBAD/NED.

Another consideration preventing the complete automation of the TORS/TORI catalog construction was the assignment of "preferred" SIMBAD/NED object names. In some cases, the targets had not yet been added to the SIMBAD/NED catalogs, so the SIMBAD/NED names were left blank. Sometimes, the correct SIMBAD/NED name could not be assigned with complete confidence and were therefore left blank. The TORI table also included "random" exposures (e.g. parallels) for which no attempt was made to determine the observed objects.

The TORI table entries were based upon "pointings". (The definition of a pointing may differ for each mission and are dscribed in the individual mission specification pages.) After determining which observations were considered part of a pointing, the selection of representative observations was further refined using filters, exposure lengths, and observation dates. Each pointing was assigned a pointing number which was used during the selection process (and also by the display program) to group the representative images.

An example of the TORS table entries follows:

Mission	Dataset Name	Mission Object Name	SIMBAD Name	NED Name	RA (2000)	Dec (2000)	Comment
GHRS	Z2QM010XT	RR-TEL	V* RR Tel		20 04 18	-55 43 32	G270M - HARPER
GHRS	Z2QM0115R	RR-TEL	V* RR Tel		20 04 18	-55 43 32	G140L - HARPER
HUT	rr-tel_24701_a	RR-TEL	V* RR Tel		20 04 18	-55 43 33	probably airglow only

Search Procedure

The scrapbook allows searches by target name or coordinates and was designed with three search options: search on coordinates, search on SIMBAD or NED "preferred" target names, and search on target names specified by the mission or observer. The use of these options is explained further in the help page. In the first ("Coordinates") option, coordinates are determined for input target names using SIMBAD or NED, and the search proceeds by selecting observations within the specified search radius (the name resolve step is skipped if the user enters coordinates directly). For the second option ("Resolved Target Name"), a string search is performed comparing the user-specified target name with the SIMBAD/NED target names stored in the TORS/TORI tables. This option is useful for searches in a crowded field, when coordinate resolution could lead to confusion. The third option ("Input Target Name") allows a user to compare the input target name to the mission/observer target name and also permits utilization of a wildcard symbol %. (The last two modes only work if the user enters a target name rather than coordinates.)

Creation of Thumbnails and Display

The final step in creating the spectral scrapbook was the design of the search results page. The page begins with a short description of the users input parameters, followed by a table describing the MAST data sets matching the users input parameters, with entries in the mission/instruments field linked to the appropriate MAST mission home page. The displayed fields correspond to the data in the TORS/TORI tables with the addition of the angular separation field (for coordinate searches) which describes the separation between the found entries and the users specified (or the name-resolver derived) coordinates.

Following the table are thumbnail plots or images, grouped by mission and/or instrument. The mission/instrument name heading each section is a link to a MAST search form which allows more detailed searches for objects within a specific MAST mission. The displayed thumbnails represent the first "n" entries found for each mission, where "n" is the optional "max thumbnails per mission" parameter from the scrapbook form, and is set to 10 by default. The thumbnails serve as "icons" for further investigation. Links under each thumbnail can be used to display "preview" plots, exposure information, downloadable data files, and literature links. For most missions the thumbnails are miniaturized versions of the preview plots. For HST missions (temporarily at least), the preview contains only a full-sized plot which is created on the fly from the HST preview database. Neither the thumbnails nor the preview plots are meant to convey quantitative information; for some spectral missions (e.g. TUES) they are equivalent to the downloadable data, but for most they are not.

Following the thumbnails is a link to the MAST cross correlation search tool. Clicking this link will display a table of the first "n" entries found in each MAST mission table for the user-specified target, where, again, "n" is the "max thumbnails per mission" parameter specified on the scrapbook search form.

MAST Spectral/Image Scrapbook Help

Help Index:

Please see also:

How we made the scrapbook

Introduction

The MAST Spectral/Image Scrapbook is designed to allow users to take a quick look at sample data in the MAST archive of a particular astronomical object of interest. It is particularly useful if the user is not already familiar with the datasets involved.

The tool utilizes a pair catalogs of representative spectra and images compiled from the MAST archive. Each of the tables lists unique datasets representing either each object or unique pointing observed by each MAST mission/instrument. These datasets contain either a calibrated spectrum or image, as the case may be. More than one dataset may be listed for an assortment of bandpasses, depending on the instrument. For instance, two GHRS spectra are included in the catalog for the star T Tauri, one for the long-wavelength and one for the short-wavelength ultraviolet ranges, among the 13 GHRS spectra in the archive. For IUE, representative images of an object are included for both low and high dispersion if they exist. For WFPC2 images only, one 2.5 x 2.5 arcmin U, B, V, R, and I image is included per pointing when available; a band centered on an emission line is also included when available. In addition, the table lists the names of the object returned by SIMBAD and NED, if available, and the name and coordinates of the object as given in the original observing catalog.

The user may query the table in one of several ways (see Search Criteria listed below):

- Enter an object name to be resolved by SIMBAD or NED, and use the SIMBAD/NED coordinates to search the catalog for any entries within a specified radius of that position.
- Enter a set of coordinates to search the catalog by position.
- Enter an object name to be resolved by SIMBAD or NED, and search the catalog for entries with that resolved name.
- Enter the mission target name to search by object name as catalogued by that mission (may include "%" as a wildcard).

Note that the individual spectra or images in the catalog are typical, not always the best quality available, and are intended to convey the general attributes and quality of the data. To explore further the data available, the user should proceed to the catalog search page for the relevant mission.

For extended objects, some missions obtained data from multiple pointings around the object. In this case for spectra, data from only a single pointing may be displayed (example: the Orion nebula). No attempt has been made to provide a listing of the various pointings for such objects.

Solar system objects are not included in this tool. A special solar system scrapbook tool is under consideration.

Input Parameters

This section describes the options available on the scrapbook search form. Only the target name or position is required; the remaining fields will default to the values shown.

Target
: Enter the name or the coordinates of the astronomical object of interest.
  - If you specify the name to be resolved for the "Coordinates" or "Resolved Target Name" search, use standard nomenclature as utilized by SIMBAD or NED for best results.
  - For the "Mission Target Name" search mode only, a "%" can be used as a wildcard and all names are converted to upper-case; e.g., entering "r136%" will return all entries in which the mission object name begins with R136.
  - To specify coordinates, enter J2000 RA and DEC as decimal degrees or as hours, minutes, and seconds. Several formats will be recognized as coordinates:
    - decimal degrees e.g. 65.4975 19.535 or 65.4975, +19.535
    - hours minutes seconds e.g. 4 21 59.4, 19 32 6 or 4 21 59.4 19 32 6
    - hours minutes, deg minutes e.g. 4 21 19 32 or 4 21, 19 32

Data Type
: The user specifiies a request for spectral or image data (but not both). By default, spectral data will be displayed.

Search Criteria
: Determines how the query of the catalog of representative spectra or images is performed. Three search options are currently available:
  - **Coordinates** - Searching the TORS/TORI tables by coordinates within the defined search radius is the default search option. Users may enter their own coordinates (consult examples under "Target"), or use the SIMBAD/NED name resolvers to obtain coordinates. The software uses the resolvers automatically when characters are entered as part of the target name. SIMBAD is the default resolver. As an example, if one enters "NGC4151" for the target, then selects "coordinates" for the search criteria and "SIMBAD" for the name resolver, the scrapbook program uses SIMBAD to determine the coordinates for NGC4151, calculates a circular search area of specified radius centered on the returned coordinates, returns all entries from either Table of Representative Spectra or Images (depending which Data Type is selected) which fall within this area, and displays the spectra or images.
  - **Resolved Target Name** - This mode compares the target name returned by SIMBAD or NED to the resolved names stored in the Table of Representative Spectra or Images. This mode is useful when looking for specific targets in crowded fields or for large extended objects, but may also miss some relevant entries. As an example of usage, if one enters "NGC 224", SIMBAD resolves the target as "M 31", and the tool returns entries from the table with the SIMBAD Name "M 31".
  - **Mission Target Name** - In this mode the user's input object name is compared directly to the mission object names without using a name resolver. The mission object names are those assigned by the mission and listed in its observing catalog. The names may or may not be consistent with those of other missions. This mode can be useful for targets with unusual designations or to find certain types of objects such as "jets". All input target names are converted to upper-case and a "%" may be used as a wildcard. If one enters "NGC%4151" for example, then entries matching "NGC4151" and "NGC 4151" will be returned. If one enters, "%JET", the entries ending in "JET" such as "HH46-JET" will be returned. This mode is the fastest to execute, but may return only a subset of the desired entries due to differences in the assigned mission object names. Warning: using wildcards can result in extremely large search results.

Search Radius
: Enter the coordinate search radius in arcminutes. The default of 3 arcmin will work for many objects, but a smaller radius may be needed in crowded fields. A larger radius may be needed to locate a large extended object. This parameter is not used when searching by name only (see above).

Maximum thumbnails per mission
: By default, a maximum of 10 thumbnails will be displayed for each mission. This value may be changed to any number greater than zero. This option affects only the display of the thumbnails. The search results table will always list all the found entries.

Name Resolver
: Select either SIMBAD (the default) or NED for name resolution. If the name is not found within either database, try entering coordinates (J2000) instead of a target name. This entry applies only to "Coordinates" and "Resolved Target Name" searches with an input name.

Submit Query
: Click on this button to begin the query. The Table of Representative Spectra or Representative Images will be searched for entries which meet the specified search criteria. The result may be none, one, or many objects. You may wish to redo the search with a smaller search radius in a crowded field, or using different search criteria.

Reset
: Clicking reset will return the form to its default values.

Help
: Clicking help will display this help file. If you still have trouble, please e-mail your question to archive@stsci.edu.

Spectrum Output

The output of your query will include a list of representative data sets for the specified object or coordinates, thumbnails of the spectra or images, and links to browse files, data, and catalog search pages. You may also select spectra to be coplotted using the Customized Plot tool.

Table Headings

Mission/Instrument
The mission and/or instrument from which the data are derived. The table entries will be linked to the appropriate MAST mission home page.

Plot
Click on the appropriate buttons to select the spectra that you would like to display together on one graph (see Customized Plot).

Dataset Name
The name of the dataset in the MAST archive. This may be a single observation or a combination of integrations, depending on the particular mission and instrument involved.

Mission Object Name
The name of the astronomical object as given in the mission catalog. Various designations were used by the different missions. Since all stored object names are upper case, all input names are converted to upper case when using the "Mission Target Name" mode.

Comments
Explanatory comments regarding the data sets. The contents will vary with mission. Currently the field describes the gratings used by GHRS spectra.

Simbad/NED Name
The name of the astronomical object as returned by SIMBAD (or NED if selected). SIMBAD (NED) is used to resolve multiple designations and to help the user determine if the MAST datasets are of the same target or of multiple targets falling within the search radius. Since some SIMBAD names contain lower case characters, input names are not converted to upper case in "Coordinates" or "Resolved Target Name" modes.

RA (2000), Dec (2000)
The right ascension and declination in J2000 epoch as listed in the Table of Representative Spectra, taken from the mission observing catalog.

Angular Separation
When performing coordinate searches, the angular separation (radius), given in arcminutes, between the SIMBAD (or NED) coordinates and the mission object coordinates listed in the Table of Representative Spectra catalog. The output entries are sorted by mission and angular separation.

Customized Plot

The spectra that you selected will be automatically scaled to the full range of wavelengths and nearly the full range of fluxes (i.e., y axis plot scale runs from 0 (or .25 * the minimum flux for spectra with negative fluxes) to the 10th highest flux). Each spectrum is automatically assigned a color, up to a maximum of 15. The spectra are labelled by their dataset names, with a summary of the datasets plotted given below the plot. After inspecting the plot, you may wish to change the selection of datasets which are displayed. Use your browser "Back" button to do this.

Plot range
Adjust the minimum and maximum wavelengths (in Ångstroms) and minimum and maximum fluxes (in erg/cm^2/sec/Å) to select the spectral region of interest and to exclude noisy data.

Plot dimensions
Adjust the X size and Y size in pixels to create the size of plot desired. The maximum dimensions are 850 by 640 pixels.

Redraw plot
Use this button to replot the spectra when you have changed the plot range or plot dimensions.

Image Output

The output of your query will include a list of representative images for the specified object or coordinates, previews of the images, and links to browse files, data, and catalog search pages.

Table Headings

Mission/Instrument
The mission and/or instrument from which the data are derived. The table entries will be linked to the appropriate MAST mission home page.

Dataset Name
The name of the dataset in the MAST archive. This may be a single observation or a combination of integrations, depending on the particular mission and instrument involved.

Mission Object Name
The name of the astronomical object as given in the mission catalog. Various designations were used by the different missions. Since all stored object names are upper case, all input names are converted to upper case when using the "Mission Target Name" mode.

Comments
Explanatory comments regarding the data sets. The contents will vary with mission. Currently the field describes the filters and apertures used for WFPC2 image data.

Simbad/NED Name
The name of the astronomical object as returned by SIMBAD (or NED if selected). SIMBAD (NED) is used to resolve multiple designations and to help the user determine if the MAST datasets are of the same target or of multiple targets falling within the search radius. Since some SIMBAD names contain lower case characters, input names are not converted to upper case in "Coordinates" or "Resolved Target Name" mode.

RA (2000), Dec (2000)
The right ascension and declination in J2000 epoch as listed in the Table of Representative Images, taken from the mission observing catalog. For WFPC2 images these refer to the position of the V1 axis, i.e., the center of the WFPC2 field of view.

Angular Separation
When performing coordinate searches, the angular separation (radius), given in arcminutes, between the SIMBAD (or NED) coordinates and the mission coordinates listed in the Table of Representative Images catalog. The output entries are sorted by mission and pointing.

Thumbnails and Links

The thumbnails displayed are small but readable quick-look versions of the calibrated data. Descriptions of how these thumbnails were created will be included in the planned mission help pages for the scrapbook.

Click on the mission/instrument name to go to the mission search page to query data from the full mission catalog. The search form will be loaded with the user-specified coordinates (or those derived from NED or SIMBAD) and the user-specified search radius, but the user may modify these or any other search parameter before searching the mission catalog.

For spectra, click on the data_id entry below each thumbnail to view the standard preview page. The preview pages contain a full-sized image of the spectrum and other associated information. Clicking on the mission name above the thumbnail will take the user to a query page filled out with the target name or coordinates and ready to be submitted. This is an alternative way of accessing mission-specific data products for the object. click on the data_id entry or the thumbnail to display a full-size image.

For non-HST missions, click on the object name listed below each thumbnail to download the data (fits files bundled in tar) to your disk. For HST data, click on the object name to display exposure informatiom.

Click on "Cross Correlation Search" to search the entire MAST archive for a listing of the MAST data sets for a particular target. This will submit the user specified target name to the "xcorr" cross correlation search form. The resolver name, number of entries displayed per mission, and the search radius specified in the scrapbook search form will also be passed to xcorr.

MAST Mission Search Help Page

Overview

This form allows one to

1. perform a quick search by target name or coordinates for a specified set of data types (default is all), or
2. list and briefly describe the available MAST missions for a specified set of data types (default is all).

Clicking the "search" button without any selection criteria will return a list of all the existing MAST data sets. The information below describes the various search options.

Note: if you already know which data set(s) you are interested in, (i.e., which mission or survey), you may instead

- click the "Data Search" link to display a list of links to mission-specific search scripts, or
- click on the mission names shown on the top MAST page to go to the mission home pages (a similiar list is displayed by clicking the "Missions" link at the top of the page).

For further assistance, contact a MAST staff member by clicking the "Contacts" link at the top of the page.

Target Name (or coordinates)
: Entering either a target name to be resolved by SIMBAD (by default) or NED, or J2000 coordinates (RA and DEC separated by a comma) will start a cross-correlation search for appropriate data sets within MAST. If data types are also selected, the search will be restricted to the selected missions.

Data Type(s)
: Archived data sets have been classified according to the type of data (i.e., spectral, image or other) and wavelength coverage. Selecting various data types and wavelength ranges and then clicking "Search", will return a list containing both a summary of each missions data holdings and a link to the mission home pages. If a particular target is also specified, the results page will list the actual data sets available from each of the selected missions.

  The wavelength ranges and data types used in the table are as defined below.

X-ray
: That portion of the electromagnetic spectrum having wavelengths from ~0.1 to ~124 Å (i.e., ~124 kev to ~100 eV).

Extreme UV
: The extreme ultraviolet wavelength range is defined as ~70 to 912 Å.

Far-UV
: The spectral region from 912 to 2000 Å.

Near-UV
: The spectral region from 2000 to 3400 Å.

Optical
: The spectral region from 3400 to ~7500 Å.

Near-IR
: The spectral region from ~7500 Å to ~30 µ.

Radio
: That portion of the electromagnetic spectrum having wavelengths greater than ~10 cm.

Images
: Image data refers to digital images obtained within various bandpasses and with various spatial resolutions. (Note: images of spectra are not included in this category.)

Spectra
: This category refers to spectroscopic data containing calibrated or uncalibrated fluxes as a function of wavelength.

Other
: Data sets listed in the "Other" category include polarimetric, photometric, and astrometric data.

MAST Cross Correlation Help

This page explains how to use the non-catalog-specific features of the MAST cross-correlation pages.

Missions
: Select one or more missions with which to cross-correlate the selected catalog. (For HST, each instrument is treated as a separate mission.) You can use the **Show catalog entries that match any/all of the selected missions** selector (see below) to control whether any or all missions have to match a catalog entry in order for that catalog entry's results to be displayed.

Radius (arcmin)
: The radius in arcminutes on which to cross-correlate the mission with the object catalog catalog. Each mission has its own independent radius. For each mission, a default radius has been chosen that is more or less appropriate for that mission.

Show catalog entries that match any/all of the selected missions
: When you select multiple missions, you can use this selector to control how an catalog row's results will be displayed: Set it to `any` to show results if the catalog entry cross-correlates with at least one of the selected missions, or set it to `all` to show only those catalog entries that cross-correlate with *every* selected mission. For example, you might set this selector to `all` if you are looking for catalog entries that have been observed with *both* HST *and* IUE, or to `any` to find catalog entries observed with *either* HST *or* IUE.

Display *n* rows per mission
: Use this selector to determine how many rows from each mission will be displayed. When `ALL` is selected, every row found for the mission will be displayed. Optionally, you may use this selector to reduce the number of rows from each mission reported, reducing the length of the results page. The *total number* of rows for each mission will always be reported.

MAST/HIPPARCOS Cross Correlation Help

This page explains how to use the MAST/HIPPARCOS cross-correlator.

You can use this page to cross-correlate subsets of the HIPPARCOS catalog with the HST, IUE, and EUVE archives. To use the form, simply indicate the V magnitude, B-V color, Parallax (mas), and/or Spectral Type that define the subset of the catalog that you're interested in, and which missions you want to cross correlate this subset with. You can optionally specify a search radius for each mission different from the default given in the page.

The MAST cross-correlator will then extract the subset of the HIPPARCOS catalog that meets your qualifications, and will begin polling the selected mission databases to see which missions have observed these stars . The results will be presented in a simple tabular form, with links to the MAST search pages for individual missions:

- The name of the catalog or mission will be linked to that mission's search form, with the RA and Dec for the catalog target as defaults.
- The target name will be linked to a preview image or spectrum, if one is available.
- The name of the exposure (the Dataset Name for HST data, the Entry ID for IUE data, etc) will be linked to a page of information about that specific observation. (This is still under development for non-HST data.)

V Magnitude
Apparent magnitude in the Johnson V band.

```
Qualification  Meaning
-------------- --------------------------------------
   > 18        V greater (dimmer) than 18
   < 22        V less (brighter) than 22
 18.5 .. 22.5  V between 18.5 and 22.5
   18.0        V of exactly 18
```

The range of values of this field in the HIPPARCOS catalog is -1.44 to 14.08. (This does not mean that the HIPPARCOS catalog is complete to 14.08.)

B-V Color
Johnson B-V color, expressed as a magnitude difference.

Parallax
Trigonometric parallax, in milliarcseconds (mas).

Spectral Type
The spectral type. This field is case-sensitive, so that searches using it will go faster. (The database engine wouldn't be able to use the index otherwise.)

Right ascension range
Right ascension range (J2000). Use this to limit the catalog extraction to a specific area of the sky. This field should be used to specify a *range* of right ascensions. While a single RA would be recognized, in general such a specification would not be useful, since the cross-correlator will try to match the RA *exactly*- an operation that would be subject to the whims of floating-point computer arithmetic.

Here's how to specify a range of right ascensions.

```
12 00 00 .. 14 00 00
12 00 .. 14 00
12h00m00s .. 14h00m00s
12h 00m 00s .. 14h 00m 00s
12h 00' 00" .. 14h 00' 00"
180 .. 210
```

Note that if the right ascension is given as a single floating-point number, as in the last line in the above set of examples, it will be interpreted as degrees, not hours.

You can also use < and >:

```
< 5 00 00
> 14 00 00
< 2, > 20
```

The last line means "less than 2 OR greater than 20". A comma may be to OR two RA qualifications.

Declination range
Declination range (J2000). Use this to limit the catalog extraction to a specific area of the sky. This field should be used to specify a *range* of declinations. While a single Dec would be recognized, in general such a specification would not be useful, since the cross-correlator will try to match the Dec *exactly*- an operation that would be subject to the whims of floating-point computer arithmetic.

Here's how to specify a range of declinations:

```
20 30 00 .. 21 00 00
20 30 .. 21 00
20h30m00s .. 21h00m00s
20h 30m 00s .. 21h 00m 00s
20h 30' 00" .. 21h 00' 00"
20.5 .. 21.0
```

You can also use < and >:

```
< 20
> -20
< -20, > 20
```

The last line means "south of -20 OR north of +20".

Missions
Select one or more missions with which to cross-correlate the selected catalog. (For HST, each instrument is treated as a separate mission.) You can use the **Show catalog entries that match any/all of the selected missions** selector (see below) to control whether any or all missions have to match a catalog entry in order for that catalog entry's results to be displayed.

Radius (arcmin)
The radius in arcminutes on which to cross-correlate the mission with the object catalog catalog. Each mission has its own independent radius. For each mission, a default radius has been chosen that is more or less appropriate for that mission.

Show catalog entries that match any/all of the selected missions
When you select multiple missions, you can use this selector to control how an catalog row's results will be displayed: Set it to `any` to show results if the catalog entry cross-correlates with at least one of the selected missions, or set it to `all` to show only those catalog entries that cross-correlate with *every* selected mission. For example, you might set this selector to `all` if you are looking for catalog entries that have been observed with *both* HST *and* IUE, or to `any` to find catalog entries observed with *either* HST *or* IUE.

Display *n* rows per mission
Use this selector to determine how many rows from each mission will be displayed. When ALL is selected, every row found for the mission will be displayed. Optionally, you may use this selector to reduce the number of rows from each mission reported, reducing the length of the results page. The *total number* of rows for each mission will always be reported.

MAST/SKYMAP SKY2000 Version 3 Correlation Help

This page explains how to use the MAST/SKY2000 cross-correlator.

Version 3 of the SKY2000 master catalog contains nearly 300,000 star entries with visual magnitudes between -1.4 and 12.92, all of which have coordinates accurate to less than or equal to 1.5 arcsec. More than 99% of the entries have Johnson V magnitudes, however note that not all the included fields have values for every star entry.

To use the SKY2000 form, simply indicate the V or B magnitude, B-V color, coordinates, Parallax (mas), and/or Spectral Type that define the subset of the catalog that you're interested in, and which missions you want to cross correlate this subset with. The page is initially displayed to search all MAST missions except FGS and HSP. To search on individual missions, first click the "unmark all" button and then select the specific missions desired. (Selecting fewer missions will speed up the search.) You can also specify a search radius for each mission different from the default given in the page.

The MAST cross-correlator will extract the subset of the SKY2000 catalog that meets your qualifications, and will begin polling the selected mission databases to see which missions have observed these stars. (Note that queries returning a large subset of the SKY2000 catalog can take a long time to complete.) The results will be presented in a simple tabular form, with links to the MAST search pages for individual missions:

- The name of the catalog or mission will be linked to that mission's search form, with the RA and Dec for the catalog target as defaults.
- The target name will be linked to a preview image or spectrum, if one is available.
- The name of the exposure (the Dataset Name for HST data, the Entry ID for IUE data, etc) will be linked to a page of information about that specific observation. (This is still under development for non-HST data.)

The MAST project wishes to thank Wayne H. Warren Jr. (Raytheon Technical Services Company) and Christopher B. Sande (Computer Sciences Corporation) for their assistance in obtaining the SKY2000 master catalog and documentation.

V Magnitude

Apparent magnitude in the Johnson V band.

```
Qualification  Meaning
-------------- ---------------------------------------
   > 18        V greater (dimmer) than 18
   < 22        V less (brighter) than 22
 18.5 .. 22.5  V between 18.5 and 22.5
   18.0        V of exactly 18
```

The range of values of this field in the SKY2000 version 3 catalog is -1.44 to 12.92. (This does not mean that the SKY2000 catalog is complete to 12.92.)

B Magnitude

Apparent magnitude in the Johnson B band. The range of values for this field is -1.43 to 16.66.

B-V Color

Johnson B-V color, expressed as a magnitude difference. Values range from -0.6 to 5.9.

Parallax

Trigonometric parallax, in milliarcseconds (mas). Values range from 742 to -343 although negative values have no physical meaning.

Spectral Type

A 30 character field containing spectral class, luminosity class, and peculiarity type. This field is case-sensitive, so that searches using it will go faster. (The database engine wouldn't be able to use the index otherwise.)

Right ascension range

Right ascension range (J2000). Use this to limit the catalog extraction to a specific area of the sky. This field should be used to specify a *range* of right ascensions. While a single RA would be recognized, in general such a specification would not be useful, since the cross-correlator will try to match the RA *exactly*- an operation that would be subject to the whims of floating-point computer arithmetic.

Here's how to specify a range of right ascensions.

```
12 00 00 .. 14 00 00
12 00 .. 14 00
12h00m00s .. 14h00m00s
12h 00m 00s .. 14h 00m 00s
12h 00' 00" .. 14h 00' 00"
180 .. 210
```

Note that if the right ascension is given as a single floating-point number, as in the last line in the above set of examples, it will be interpreted as degrees, not hours.

You can also use < and >:

```
< 5 00 00
> 14 00 00
< 2, > 20
```

The last line means "less than 2 OR greater than 20". A comma may be to OR two RA qualifications.

Declination range

Declination range (J2000). Use this to limit the catalog extraction to a specific area of the sky. This field should be used to specify a *range* of declinations. While a single Dec would be recognized, in general such a specification would not be useful, since the cross-correlator will try to match the Dec *exactly*- an operation that would be subject to the whims of floating-point computer arithmetic.

Here's how to specify a range of declinations:

```
20 30 00 .. 21 00 00
20 30 .. 21 00
20h30m00s .. 21h00m00s
20h 30m 00s .. 21h 00m 00s
20h 30' 00" .. 21h 00' 00"
20.5 .. 21.0
```

You can also use < and >:

```
< 20
> -20
< -20, > 20
```

The last line means "south of -20 OR north of +20".

Missions

Select one or more missions with which to cross-correlate the selected catalog. (For HST, each instrument is treated as a separate mission.) You can use the **Show catalog entries that match any/all of the selected missions** selector (see below) to control whether any or all missions have to match a catalog entry in order for that catalog entry's results to be displayed.

Radius (arcmin)

The radius in arcminutes on which to cross-correlate the mission with the object catalog. Each mission has its own independent radius. For each mission, a default radius has been chosen that is more or less appropriate for that mission.

Show catalog entries that match any/all of the selected missions

When you select multiple missions, you can use this selector to control how a catalog row's results will be displayed: Set it to `any` to show results if the catalog entry cross-correlates with at least one of the selected missions, or set it to `all` to show only those catalog entries that cross-correlate with *every* selected mission. For example, you might set this selector to `all` if you are looking for catalog entries that have been observed with *both* HST *and* IUE, or to `any` to find catalog entries observed with *either* HST *or* IUE.

Display *n* rows per mission

Use this selector to determine how many rows from each mission will be displayed. When `ALL` is selected, every row found for the mission will be displayed. Optionally, you may use this selector to reduce the number of rows from each mission reported, reducing the length of the results page. The *total number* of rows for each mission will always be reported.

MAST/AGN Cross Correlation Help

This page explains how to use the MAST/AGN cross-correlator. For information on how the AGN catalog was constructed, see the page describing the contents of the AGN catalog.

You can use this page to cross-correlate subsets of our AGN catalog with the HST, IUE, and EUVE archives. To use the form, simply indicate the classes, redshift range, visual magnitude range, and/or 6cm flux range that define the subset of the AGN that you're interested in, and which missions you want to cross correlate this subset with. You can optionally specify a search radius for each mission different from the default given in the page.

The MAST cross-correlator will then extract the subset of the AGN catalog that meets your qualifications, and will begin polling the selected mission databases to see which missions have observed the AGN. The results will be presented in a simple tabular form, with links to the MAST search pages for individual missions:

- The name of the catalog or mission will be linked to that mission's search form, with the RA and Dec for the catalog target as defaults.
- The target name will be linked to a preview image or spectrum, if one is available.
- The name of the exposure (the Dataset Name for HST data, the Entry ID for IUE data, etc) will be linked to a page of information about that specific observation. (This is still under development for non-HST data.)

Object Class

The classification of the AGN. For information on how the AGN were classified, see the section The Classification in the page describing the contents of the AGN catalog.

You may select one or more of these classifications. If you select more than one, then the cut will find AGN that fall into any one of the selected classes. (Each AGN has only one class associated with it.)

Redshift

The redshift of the AGN, expressed as *z*. You can enter a range of floating point numbers here in any of the following ways:

Qualification	Meaning
> 4	*z* greater than 4
< 2	*z* less than 2
2.5 .. 3.5	*z* between 2.5 and 3.5
2.0	*z* of exactly 2

Visual Magnitude

The visual magnitude (*V*) of the AGN. For information on how the visual magnitude was derived, see the page describing the contents of the AGN catalog.

This field can accept a range of floating point numbers:

Qualification	Meaning
> 18	*V* greater (dimmer) than 18
< 22	*V* less (brighter) than 22
18.5 .. 22.5	*V* between 18.5 and 22.5
18.0	*V* of exactly 18

6cm Flux

The radio flux at 6cm, in mJy. For information on how the 6cm flux was derived, see the page describing the contents of the AGN catalog.

This field can accept a range of floating point numbers:

Qualification	Meaning
> 18	flux greater than 18 mJy
< 22	flux less than 22 mJy
18.5 .. 22.5	flux between 18.5 mJy and 22.5 mJy
18.0	flux of exactly 18 mJy

Missions

Select one or more missions with which to cross-correlate the selected catalog. (For HST, each instrument is treated as a separate mission.) You can use the **Show catalog entries that match any/all of the selected missions** selector (see below) to control whether any or all missions have to match a catalog entry in order for that catalog entry's results to be displayed.

Radius (arcmin)

The radius in arcminutes on which to cross-correlate the mission with the object catalog catalog. Each mission has its own independent radius. For each mission, a default radius has been chosen that is more or less appropriate for that mission.

Show catalog entries that match any/all of the selected missions

When you select multiple missions, you can use this selector to control how an catalog row's results will be displayed: Set it to `any` to show results if the catalog entry cross-correlates with at least one of the selected missions, or set it to `all` to show only those catalog entries that cross-correlate with *every* selected mission. For example, you might set this selector to `all` if you are looking for catalog entries that have been observed with *both* HST *and* IUE, or to `any` to find catalog entries observed with *either* HST *or* IUE.

Display *n* rows per mission

Use this selector to determine how many rows from each mission will be displayed. When ALL is selected, every row found for the mission will be displayed. Optionally, you may use this selector to reduce the number of rows from each mission reported, reducing the length of the results page. The *total number* of rows for each mission will always be reported.

The AGN Catalog

- The Classification
- Useful Hints
- Disclaimer

The Catalog

The Active Galactic Nuclei (AGN) catalog is heavily based on A Catalogue of Quasars and Active Nuclei (7th Edition), ESO Scientific Report No. 17, by Véron-Cetty & Véron (1996) [VV96]. That includes 11,442 quasars and active galaxies, and gives optical magnitudes, redshift, and some radio information. To this we have added: 1. the BL Lac catalog of Padovani & Giommi (1995), updated with BL Lacs discovered in 1996 (for a total of 265 sources); 2. the radio galaxies in the 1 Jy, S4, and S5 radio catalogs, mostly not included in VV96. The resulting database, which totals 12,021 AGN, was also cross-correlated with various radio catalogs providing 6 cm data, namely the PKS database, the PMN survey , the GB6 catalog, the 1 Jy, S4, and S5 radio catalogues. Individual radio fluxes for radio-quiet AGN not included in radio catalogs (radio fluxes < 1 - 30 mJy), taken from the literature, were also added. The V magnitudes in VV96 are actually mostly B or photographic magnitudes when no (B-V) value is available. Therefore, for objects without (B-V) colors, V magnitudes have been derived from the given values by subtracting (B-V) values typical of the class to which an object belongs to, unless the reference was to a paper which gave V magnitudes directly. One should remember that most AGN are variable so the reported V magnitudes should be taken only as indicative. (See Padovani (1997) and Padovani et al. (1997) for some astrophysical applications of an extended version of the catalog.)

The Classification

The classification is based mostly on the one given by VV6, to which the user is referred to, with some differences and additions. Namely:

- AGN UNCLASSIFIED: unclassified sources in Table 3 of VV96 (which includes "active galaxies").
- BL LAC: sources appearing in the BL Lac catalogue of Padovani & Giommi (1995), updated with BL Lacs discovered in 1996.
- LINER: classified as S3 (or Seyfert 3) in VV96.
- QSO: this includes all quasars appearing in Table 1 of VV96, defined by a value of the blue absolute magnitude brighter than -23; for these objects a sub-classification as radio-loud or radio-quiet has been done, based on the two point spectral index alpha_ro (defined here between 5000 Angstroms and 6 cm [5 GHz]). Objects with (K-corrected) alpha_ro > 0.19 (corresponding to the "standard" dividing value of radio flux to optical flux > 10) have been called radio-loud. For the purpose of calculating alpha_ro, V magnitudes have been corrected for extinction following Wilkes et al. (1994) and for the presence of emission lines according to Natali et al. (1998). Radio-loud Seyfert 1 galaxies have been included with the radio-loud QSO, where they belong according to unified schemes for AGN (see, e.g., Urry & Padovani 1995). Note that sometimes radio fluxes are available only at wavelengths other than 6 cm (e.g., from the FIRST or NVSS surveys). In these cases the radio flux at 6 cm used to calculate alpha_ro has been derived by extrapolating the flux assuming a radio spectral index typical of the class to which an object belongs to.
  - QSO (NO V-MAG): 196 QSO without (believe it or not) V magnitude;
  - QSO RADIO-LOUD; QSO (and Seyfert 1 galaxies) with alpha_ro > 0.19 (includes a few QSO without V magnitude but radio flux > 0.5 Jy);
  - QSO RADIO-QUIET; QSO with alpha_ro <= 0.19.
- RADIO GALAXY; from the 1 Jy, S4, and S5; also, radio-loud Seyfert 2 galaxies were checked individually and classified as radio-galaxies if appropriate (radio galaxies are classified as Seyfert 2 galaxies in VV96).
- SEYFERT TYPE 1; sources in Table 3 of VV96 classified as S1 (excluding objects with broad lines in polarized light only); radio-loud Seyfert 1 galaxies are included with the radio-loud QSO (see above).
- SEYFERT TYPE 2; sources in Table 3 of VV96 classified as S2, plus S1 in VV96 with broad lines in polarized light only (classified as S1 in VV96).
- SEYFERT?; sources in Table 3 of VV96 classified as S or S?.
- STARBURST GALAXY; sources in Table 3 of VV96 classified as H2.

Useful Hints

(work in progress)

Disclaimer

Classification of astronomical objects is a complex subject and in many cases the assignement of an object to a given class can be a matter of dispute. We have done our best to be as objective as possible but are obviously open to comments and suggestions about the catalog. These should be sent, along with any questions, to Archive hotseat.

MAST/Abell Clusters Cross Correlation Help

This page explains how to use the MAST/Abell Clusters cross-correlator.

You can use this page to cross-correlate subsets of the Abell Clusters catalog with the currently archived MAST missions. To use the form, simply indicate the redshift range, visual magnitude range (see below), richness class(es), and/or a range of galactic coordinates that define the subset of the clusters that you're interested in, and which missions you want to cross correlate this subset with. You can optionally specify a search radius for each mission different from the default given in the page.

The MAST cross-correlator will then extract the subset of the Abell Clusters catalog that meets your qualifications, and will begin polling the selected mission databases to see which missions have observed the clusters. The results will be presented in a simple tabular form, with links to the MAST search pages for individual missions:

- The name of the catalog or mission will be linked to that mission's search form, with the RA and Dec for the catalog target as defaults.
- The target name will be linked to a preview image or spectrum, if one is available.
- The name of the exposure (the Dataset Name for HST data, the Entry ID for IUE data, etc) will be linked to a page of information about that specific observation. (This is still under development for non-HST data.)

A note about the search radius: Abell clusters can be large, so a search radius on the order of the instrument aperture may be too small. We have therefore defined radii for all of the clusters for which we have a valid redshift. The search radius will be the cluster radius (in arcminutes) *plus* the aperture radius for the instrument. (Clusters for which a radius has not been defined- because a redshift was not available- will be searched on the aperture radius alone.)

Richness Class

The richness class of the cluster.

You may select one or more richness class. If you select more than one, then the cross-correlator will find clusters that fall into any one of the selected classes.

Redshift

The redshift of the cluster, expressed as z. You can enter a range of floating point numbers here in any of the following ways:

```
Qualification  Meaning
-------------- ---------------------------------------
    > .75      z greater than .75
    < .3       z less than .3
 .3 .. .75     z between .3 and .75
    .3         z of exactly .3
```

Mag 10

The visual magnitude (*V*) of the 10th-brightest galaxy in the cluster. This field can accept a range of floating point numbers:

```
Qualification  Meaning
-------------- ---------------------------------------
   > 18        V greater (dimmer) than 18
   < 22        V less (brighter) than 22
 18.5 .. 22.5  V between 18.5 and 22.5
   18.0        V of exactly 18
```

Galactic Longitude Range

Galactic longitude range (*lii*). Use this field to restrict the catalog to a range of galactic longitudes.

This field can accept a range of floating point numbers:

```
Qualification  Meaning
-------------- ---------------------------------------
   > 270       lii greater than 270 degrees
   < 30        lii less than 30 degrees
 160 .. 200    lii between 160 and 200 degrees
 < 30, > 270   lii between 270 and 30 degrees (including 0 degrees)
```

If you enter a single floating-point number, the cross-correlator will try to match that number exactly, so this probably isn't a useful way to qualify this field.

Galactic Latitude Range

Galactic latitude range (*bii*). Use this field to restrict the catalog to a range of galactic latitudes.

This field can accept a range of floating point numbers:

```
Qualification  Meaning
-------------- ---------------------------------------
   > 60        bii greater than 60 degrees
   < -60       bii less than -60 degrees
 -30 .. 30     bii between -30 and +30 degrees
< -60, > 60    bii less than -60 or greater than +60 degrees
```

If you enter a single floating-point number, the cross-correlator will try to match that number exactly, so this probably isn't a useful way to qualify this field.

Missions

Select one or more missions with which to cross-correlate the selected catalog. (For HST, each instrument is treated as a separate mission.) You can use the **Show catalog entries that match any/all of the selected missions** selector (see below) to control whether any or all missions have to match a catalog entry in order for that catalog entry's results to be displayed.

Radius (arcmin)

The radius in arcminutes on which to cross-correlate the mission with the object catalog. Each mission has its own independent radius. For each mission, a default radius has been chosen that is more or less appropriate for that mission.

Show catalog entries that match any/all of the selected missions

When you select multiple missions, you can use this selector to control how an catalog row's results will be displayed: Set it to `any` to show results if the catalog entry cross-correlates with at least one of the selected missions, or set it to `all` to show only those catalog entries that cross-correlate with *every* selected mission. For example, you might set this selector to `all` if you are looking for catalog entries that have been observed with *both* HST *and* IUE, or to `any` to find catalog entries observed with *either* HST *or* IUE.

Display *n* rows per mission

Use this selector to determine how many rows from each mission will be displayed. When `ALL` is selected, every row found for the mission will be displayed. Optionally, you may use this selector to reduce the number of rows from each mission reported, reducing the length of the results page. The *total number* of rows for each mission will always be reported.

MAST Cross Correlation Help

This page explains how to use the MAST cross-correlator.

You can use this page to cross-correlate a list of sky positions with the HST, IUE, and EUVE archives. To use the form, you will need a file containing the list of sky positions you want to use as an input catalog. The format of this file is discussed below. Also, select which missions you want to cross correlate this input catalog with. You can optionally specify a search radius for each mission different form the default given in the page.

The MAST cross-correlator will then parse your input catalog and begin polling the selected mission databases to see which missions have observations at your catalog potisions. The results will be presented in a simple tabular form, with links to the MAST search pages for individual missions.

Format of the Input File

The input file should have one entry per row; blank lines and lines beginning with a # character will be ignored. Each row should contain columns delimited by one of the column-delimiting characters shown in the Column Delimiter popup menu in the form. (currently, these are tab, comma, pipe, semicolon, and colon). The RA and Dec can appear in any column. (Currently, the coordinates will be assumed to be equatorial with an equinox of J2000.)

Here are some examples of input-file formats:

- Comma-delimited file, RA in column 1, Dec in column 2:

```
240.083157,-22.621305,HD143275
261.347982,-56.377399,HD157246
67.278648,-13.048497,HD28497
24.426019,-57.236367,HD10144
```

- Pipe-delimited file, RA in column 2, Dec in column 3:

```
HD143275 | 16:00:19 | -22:37:16
HD157246 | 17:25:23 | -56:22:38
HD28497  | 04:29:06 | -13:02:54
HD10144  | 01:37:42 | -57:14:10
```

- Tab-delimited file, RA in column 1, Dec in column 2, with a comment line (which will be skipped):

```
# RA              Dec
16 00 19        -22 37 16
17 25 23        -56 22 38
04 29 06        -13 02 54
01 37 42        -57 14 10
```

Make sure that each column is separated by only one delimiter.

Once you have your input file, in the cross-correlation form, indicate the name of the file on your system, the character which delimits the columns (see below), and the column numbers of the RA and Dec (see below). Then hit the **Submit Query** button. Your browser will then send the contents of your input file to our server, which will search the Archive at the positions given in your input file. (Your file will not be saved on the server; it will be deleted as soon as the cross-correlation ends or the CGI script dies.)

Path to Your Local File

The pathname to the catalog file on your disk. Your browser will send the contents of this file to the cross-correlator to use as an input catalog. Depending on your browser and your platform, you may need to give the full path to this file (e.g., `/home/kimball/xcorr.lis`).

Column Delimiter

This is the character that delimits the columns in your file. The choice is currently limited to tab, comma, pipe (or vertical bar), semicolons, and colons. Let us know if you think something else would be useful here.

The cross-correlator currently cannot handle input lists of fixed-length records. When we work out a reasonable interface for this, however, we'll implement it.

RA Column Number, Dec Column Number

These are the column numbers of the RA and Dec columns within your file. The first column is assumed to be column #1.

Sometimes a catalog will start with a column-delimiting character. For example, if your catalog looks like this:

```
| HD143275 | 16:00:19 | -22:37:16 |
| HD157246 | 17:25:23 | -56:22:38 |
| HD28497  | 04:29:06 | -13:02:54 |
| HD10144  | 01:37:42 | -57:14:10 |
```

then the cross-correlator will think that column 1 is always empty, so you should start counting columns at column #2. Therefore, in this example, the RA will be in column #3 and the Dec in column #4.

Missions

Select one or more missions with which to cross-correlate your input catalog. You can use the **Show catalog entries that match any/all of the selected missions** selector (see below) to control whether any or all missions have to match and catalog row in order for that row's results to be displayed.

Radius (arcmin)

The radius in arcminutes on which to cross-correlate the mission with the input catalog. Each mission has its own independent radius. For each mission, a default radius has been chosen that is more or less appropriate for that mission. (Later on, we may break HST up into its individual instruments, treating each one like a separate mission. In that case, these fields will have default values appropriate for that instrument.)

Show catalog entries that match any/all of the selected missions

When you select multiple missions, you can use this selector to control how a catalog row's results will be displayed: Set it to `any` to show results if the catalog entry cross-correlates with at least one of the selected missions, or set it to `all` to show only those entries that cross-correlate with *every* selected mission. For example, you might set this selector to `all` if you are looking for catalog entries that have been observed with *both* HST *and* IUE, or to `any` to find entries observed with *either* HST *or* IUE.

Display *n* rows per mission

Use this selector to determine how many rows from each mission will be displayed. When `ALL` is selected, every row found for the mission will be displayed. Optionally, you may use this selector to reduce the number of rows from each mission reported, reducing the length of the results page. The *total number* of rows for each mission will always be reported.

What's New Help

Overview

In order to allow more specific listings of changes within MAST, the user may now select both the mission and time period for which to view changes. Once these options are choosen, clicking **GO** will generate and display the requested list of changes.

The **What's New** links available from the individual mission pages access the same master list of changes, but the link is hardcoded with the mission name and a time period of 1 year. In other words, clicking the Whats New link from the mission pages will display changes for that particular mission made during the past year.

Mission
: This entry specifies the mission for which to view changes. Besides the current MAST-supported missions (i.e., BEFS, COPERNICUS, DSS, EUVE, FIRST, FUSE, HST, HUT, IUE, IMAPS, ROSAT, UIT, and WUPPE), one may also select ALL (the default selection) or OTHER, which describes general changes not related to a particular mission (note ALL includes OTHER).

Time Period
: The period of time over which to view MAST-related changes, starting from the day the list is generated. The current options include: last month, last 3 months (the default), last 6 months, last year, and all.

SDSS Unusual BAL Quasars

A sample of 23 unusual Broad Absorption Line Quasars has been assembled from both the SDSS EDR and some post-EDR data, totalling approximately 8000 quasar spectra. No further examples of the five categories of unusual BAL quasars discussed in the paper could be found among the data inspected, at least for spectra with SNR at least 6 per pixel in at least one of the g, r, or i bands (see section 4 of the paper). The paper also presents a revised balnicity index for deciding whether a quasar is a BAL quasar or not.

Calibrated SDSS and followup spectra of all 23 objects, plus IRAF and SM code for calculating the traditional and revised balnicity indices, are available in a gzipped tar file.

Questions regarding the BAL quasar work can be addressed to the lead author, Pat Hall (pathall@astro.princeton.edu), of Princeton University.

- gzip-compressed PostScript file of the paper as accepted by the Astrophysical Journal Supplement on 2002 March 1. (2.3 Mbytes)
- gzip-compressed tar file sb1data.tar.gz (1.1 Mbytes) containing spectra of all unusual BAL quasars in the paper along with the IRAF and SM code for calculating traditional and revised balnicities.

The Sloan Digital Sky Survey Quasar Target Selection Algorithm

---

Paper abstract:
We describe the algorithm for selecting quasar candidates for optical spectroscopy in the Sloan Digital Sky Survey. Quasar candidates are selected via their non-stellar colors in *ugriz* broad-band photometry, and by matching unresolved sources to the FIRST radio catalogs. The automated algorithm is sensitive to quasars at all redshifts lower than z~5.8. Extended sources are also targeted as low-redshift quasar candidates in order to investigate the evolution of Active Galactic Nuclei (AGN) at the faint end of the luminosity function. Nearly 95% of previously known quasars are recovered (based on 1540 quasars in 446 square degrees). The overall completeness, estimated from simulated quasars, is expected to be over 90%, whereas the overall efficiency (quasars:quasar candidates) is better than 65%. The selection algorithm targets ultraviolet excess quasars to i^*=19.1 and higher-redshift (z>3) quasars to i^*=20.2, yielding approximately 18 candidates per square degree. In addition to selecting ``normal'' quasars, the design of the algorithm makes it sensitive to atypical AGN such as Broad Absorption Line quasars and heavily reddened quasars.

The algorithm was approved for normal SDSS operations on 2001 August 24; spectra of quasar candidates that were identified from imaging data processed after that date will thus constitute a uniformly selected sample of SDSS quasars. Note that the quasars from the EDR quasar catalog were *not* selected with this verion of the algorithm and are thus not a uniform sample. An updated quasar catalog that is uniformly selected according to this algorithm will be released concurrent with the next SDSS data release, currently scheduled for January 2003.

Questions regarding the quasar selection algorithm can be addressed to the lead author, Gordon Richards (gtr@astro.psu.edu), of the Department of Astronomy and Astrophysics at The Pennsylvania State University.

Sloan Digital Sky Survey Quasar Catalog

The Sloan Digital Sky Survey Quasar Catalog consists of 3814 objects (3000 discovered by the SDSS) contained in the initial public release. Each object has at least 1 emission line with a full width at half maximum larger than 1000 km/s, luminosities brighter than M(i*)=-23 and highly reliable redshifts. The area covered by the catalog is 494 square degrees; most of the objects were found in SDSS commissioning data using a multicolor selection technique. The quasar redshifts range from 0.15-5.03.

Calibrated spectra of all objects in the catalog, from 3800-9200 Angstroms, are also available in a gzipped tar file.

Notes: the sample is not homogeneous and is not intended for statistical analysis. The lead author is Donald Schneider from the Dept. of Astronomy and Astrophysics at Penn State University (dps@astro.psu.edu). This sample is the preferred quasar catalog for Sloan analysis, and should supercede the quasar catalog in the EDR.

- PostScript file of the paper as submitted to the Astronomical Journal in October 2001. (1.3 Mbytes)
- ASCII Catalog (0.7 Mbytes)
- A gzipped (compressed) tarfile containing a FITS spectrum for each of the 3814 quasars: edrqsosp.tar.gz (WARNING: very large filesize of 245 MBytes, 623 MBytes uncompressed)
- A web-based EDR QUASAR search interface, developed by MAST, allows you to search the EDR Quasar catalog and retrieve individual spectra. A "simple" and an "advanced" interface are both available. This interface is a generic MAST data retrieval interface, under development by MAST. Comments to archive@stsci.edu are welcome.

Magellanic Cloud Planetary Nebulae

Image collections

These image collections contain GIF thumbnail representations of the data. Some of these pages may load slowly because they contain many images. The actual FITS data can be accessed via the observations page.

- Large Magellanic Cloud (LMC) gallery
  Thumbnail images of key emission features from STIS slitless spectra for LMC objects from programs 8271, 8702, and 6407: broadband, [O III], H-alpha and [N II]. Also some Stroemgren y images from WFPC2 observations.
- Large Magellanic Cloud (LMC) gallery - latest images*
  Thumbnail images of key emission features from STIS slitless spectra for LMC objects from program 9077: broadband, [O III], H-alpha and [N II].
- LMC morphology sequence
  The Large Magellanic Cloud (LMC) planetary nebulae organized by morphological type.
- LMC color composites
  Color composite images of selected Large Magellanic Cloud (LMC) planetary nebulae, created for press release.
- Small Magellanic Cloud (SMC) gallery*
  Thumbnail images of key emission features from STIS slitless spectra for all of our SMC objects: broadband, [O III], H-alpha and [N II].
- Blades FOC images
  Mostly deconvolved pre-COSTAR images of LMC and SMC planetary nebulae made with the Faint Object Camera (FOC) by Chris Blades. See ApJ 510:687 10 Jan 99.

Magellanic Cloud Planetary Nebulae

Data reduction and analysis

Details on data calibration and the measurements below can be found in ApJ, 548, 727 (Shaw et al., 2001).

- LMC and SMC* notebooks
  Detailed notes for each object.
- LMC and SMC* measurements and classifications
  Basic measurements such as dimensions, coordinates, central star photometry, morphological classifications, and contour plots.
- LMC* and SMC* flux measurements
  Emission line fluxes and ratios for each object, and spectral plots.

Planetary nebulae (PNs) are the gaseous relics of the outermost red giant layers, ejected as a superwind after the Asymptotic Giant Branch (AGB) phase. They carry a wealth of information on the evolution of their progenitor stars, and they retain information on the galaxian environment at the time of the formation of their progenitors. In short, they are the ideal probes of stellar evolution and formation of those stars that undergo the AGB phase.

The importance of studying Magellanic Cloud Planetary Nebulae (MCPN) is twofold: it allows the determination of physical parameters of PNs and their central stars, since their distances are known (as opposed to Galactic PN distances, that suffer large uncertainties); and they are the ideal probes of stellar evolution in low-metallicity galaxies. Small Magellanic Cloud PNs are probably the only direct way to study evolved stellar populations in a very low metallicity environment.

Our project is based on Hubble Space Telescope (HST) imaging with STIS and WFPC2, and optical and ultraviolet slitless spectroscopy. Only with HST can Magellanic Cloud PNs be resolved in their sizes and shapes, and their central stars can be detected. Ground based spectroscopic studies have been used to determine the plasma abundance of the nebulae.

WFPC2 Pointings

Coordinates: Choose either a more traditional search by Target Name/Coordinate, or the serendipitous approach, to search by RA/Dec/Galatic Latitude and/or Ecliptic Latitude ranges. You do not have to search by coordinates at all.

Target Name/Coordinates | Resolver: SIMBAD | Radius (arcmin): 3.0

RA Range ____ degrees **Dec Range** ____ degrees

Galactic Latitude Above & Below Plane > ± ____ degrees

Ecliptic Latitude Above & Below Plane > ± ____ degrees

Band: To search for specific bands, enter the number of exposures required per band (e.g. 4, >1, or <10). Specify if the search is to be for all specified bands (and) or any of the specified bands (or).

(•) And ( ) Or

U	B	V	R	I	Narrow Line

Exposure Times: To query on exposure times, enter exposure limits (in seconds) for the total exposure time in each band (e.g. >1000, or <10). Specify if the search is to be for all specified bands (and) or any of the specified bands (or).

(•) And ( ) Or

U	B	V	R	I	Narrow Line

# of Unique Bands	Total # of Exposures	# of Days between first & last exp.	Min. Total Exposure Time

Submit Query | Reset | Max Number of Pointings displayed: 100 | Help

MAST Pointings Help

Help Index:

Introduction

The MAST "Pointings" interface allows a user to search for WFPC2 exposures in a new powerful way. We have assembled a searchable data table that allows users to look for sky regions (or pointings) which have been observed more than N times, observed with 2 or more filters, or has been observed more than twice with a time separation of more than (or less than) N days. An exposure is defined to be the file created after the shutter closes. (So a CR-SPLIT results in at least 2 exposures.) All exposures within a 40 arcsecond radius are considered one "pointing". The total number of exposures within the U, B, V, R, I and for Narrow Line filters were tallied for each pointing. Included in the table are the total number of exposures for a pointing and the number of unique bands. Each band is defined by 3-4 WFPC2 filters (see Table). Filters not in this table, or exposures made with more than one filter were classified as "other" and were included in the total number of exposures. Note that an individual dataset might cover one or more pointings. The table also lists the date/time of first and last exposure for every pointing.

Because the definition of a "pointing" is a little arbitrary, results from this table should be regarded as a starting point for a continued search and subsequent retrieval request.

An example of the kind of query this table will allow is: How many high galactic latitude observations exist [for RA between 9 - 18 hours in the northern hemisphere (dec > -20) observable from the northern hemisphere in the early spring] where there has been at least two observations, and where at least one of those observations was in the I-band, and at least one of those observations was in any other filter?

Galactic Latitude Above & below plane +/- > 20.0 degrees
Band I >0
Number of Unique Bands >1
Total Number of Exposures >1
RA 09..18
Dec >-20.0

Filter choice for all bands					
U	**B**	**V**	**R**	**I**	**Line**
F300W	F450W	F606W	F702W	F814W	F656N
F336W	F439W	F555W	F675W	F791W	F673N
F255W	F467M	F569W	F622W	F785LP	F502N
F380W	F410M	F547M			F658N

Input Parameters

This section describes the options available

Coordinate Query Options
The first section of the search form contains the various coordinate search options that may be included in the query. Note that the RA/Dec range options may be combined with either the galactic or ecliptic latitude options. Entering a target name or specific coordinates for Target Name/Equatorial Coordinates however, may not be combined with the other coordinate search options.

Target Name/Equatorial Coordinates
Enter the name or the coordinates of the astronomical object of interest.
- If you specify the name to be resolved for the "Coordinates" or "Resolved Target Name" search, use standard nomenclature as utilized by SIMBAD or NED for best results.
- For the "Mission Target Name" search mode only, a "%" can be used as a wildcard and all names are converted to upper-case; e.g., entering "r136%" will return all entries in which the mission object name begins with R136.
- To specify coordinates, enter J2000 RA and DEC as decimal degrees or as hours, minutes, and seconds. Several formats will be recognized as coordinates:
  - decimal degrees e.g. 65.4975 19.535 or 65.4975, +19.535
  - hours minutes seconds e.g. 4 21 59.4, 19 32 6 or 4 21 59.4 19 32 6
  - hours minutes, deg minutes e.g. 4 21 19 32 or 4 21, 19 32

Name Resolver
Select either SIMBAD (the default) or NED for name resolution. If the name is not found within either database, try entering coordinates (J2000) instead of a target name. This parameter applies only to the "Target Name/Coordinates" search option.

Search Radius
Enter the coordinate search radius in arcminutes. The default of 3 arcmin will work for many objects, but a smaller radius may be needed in crowded fields. A larger radius may be needed to locate a large extended object. This parameter applies only to the "Target Name/Coordinates" search option.

RA/DEC Range
Specify a start & end RA and/or DEC in decimal degrees (J2000) using the "x .. y" syntax. For example, to search for all pointings between 10 and 30 degrees, enter: **10 .. 30** . Other possible conditions include: **<, >, <=,** or **>=** .

Galactic Latitude
Search on galactic latitude.
- **Above & Below Plane >:** ± Search above or below the galactic plane using designated latitude. e.g. entering 20 in > box will result in search where galactic latitude > +20 and < -20.
- **Within Plane <** ± Search within the galactic plane the galactic plane using designated latitude. e.g. entering 20 in the box will result in search where galactic latitude < +20 and > -20.
- **>** Search where galactic latitude is greater than number entered: e.g. entering 20 in the box will result in search where galactic latitude > 20
- **<** Search where galactic latitude is less than number entered: e.g. entering 20 in the box will result in search where galactic latitude < 20.

Ecliptic Latitude
Search on ecliptic latitude.
- **Above & Below Plane >** ± Search above or below the ecliptic plane using designated latitude. e.g. entering 20 in > box will result in search where ecliptic latitude > +20 and < -20.
- **Within Plane <** ± Search within the ecliptic plane the ecliptic plane using designated latitude. e.g. entering 20 in the box will result in search where ecliptic latitude < +20 and > -20.
- **>** Search where ecliptic latitude is greater than number entered: e.g. entering 20 in the box will result in search where ecliptic latitude > 20
- **<** Search where ecliptic latitude is less than number entered: e.g. entering 20 in the box will result in search where ecliptic latitude < 20

Band
Specify specific bands for the search. If nothing is entered into any bands, bands are not used for search criteria.

Specify if selection is to be on all bands chosen (and) or on any of the bands chosen.
- **And** Select on all bands designated
- **Or** select on any bands chosen
- **U** Enter the number of U band exposures required (e.g. 2, >=2, <10)
- **B** Enter the number of B band exposures required (e.g. 2, >=2, <10)
- **V** Enter the number of V band exposures required (e.g. 2, >=2, <10)
- **R** Enter the number of R band exposures required (e.g. 2, >=2, <10)
- **I** Enter the number of I band exposures required (e.g. 2, >=2, <10)
- **Line** Enter the number of Narrow band exposures required (e.g. 2, >=2, <10)

The filter numbers in the table refer to wavelength in nanometers.

Filter choice for all bands					
U	**B**	**V**	**R**	**I**	**Line**
F300W	F450W	F606W	F702W	F814W	F656N
F336W	F439W	F555W	F675W	F791W	F673N
F255W	F467M	F569W	F622W	F785LP	F502N
F380W	F410M	F547M			F658N

Exposure Times
Enter exposure limits (in seconds) for the total exposure time in each desired band (e.g. >1000, or <10). You may also specify if the search is to be for all specified bands (and) or any of the specified bands (or). For example, specifying "And" and entering >100 for "U" and >100 for "B" will return pointings for which the total exposure times are > 100 seconds in the U filter and > 100 seconds in the B filter. Specifying "Or" would return all pointings for which the total exposure times are > 100 seconds in the U filter or > 100 seconds in the B filter.

Number of Unique Bands
Enter a restriction for the number of unique filters.

Number of Exposures
Enter the number of for the total number of exposures e.g. <30

Number of Days between first and last exposure
Enter the number of days required between the first and last exposure. Entering >365 will look for pointings with exposures taken at least a year apart.

Submit Query
Click on this button to begin the query. The Pointings Tables will be searched for entries which meet the specified search criteria. The result may be none, one, or

many objects. You may wish to redo the search with a smaller search radius in a crowded field, or using different search criteria.

Reset
Clicking reset will return the form to its default values.

Maximum Number of Pointings Displayed
The maximum number of rows (i.e., pointings) to be displayed on the search results page. Allowed values are 10, 100, 500, 1000, and 5000. The default is 100. Note displaying more rows will increase execution time.

Help
Clicking help will display this help file. If you still have trouble, please e-mail your question to archive@stsci.edu.

Output

The output of your query will include three parts:

- A summary section including a definition of the query used to interrogate the database, and a summary table containing the total number of pointings found, the total number of unique exposures found, etc. (See summary table heading descriptions below.)
- A table of pointing entrees in which each row represents one pointing matching the users search criteria. See descritpion of pointings table below.
- Links in the above two tables allow a third table to be displayed which describes information about the individual exposures contained in the selected pointing or pointings. (See exposures table description below.)

Summary Table

This table summarizes the search results. Note that clicking on the filter entrees in either the Summary table or the Pointings table will display the individual exposures described by the table entry. The summary table column headings are described below.

Mission/Instrument
The mission and/or instrument from which the data are derived. The table entries will be linked to the appropriate MAST mission home page. Currently only information concerning HST/WFPC2 pointings are avaiable in the pointings table.

# of Pointings
Total number of pointings found for a given query, where a pointing is defined as a group of exposures falling within a 40 arcsecond radius.

Exposures
Total number of **unique** exposures for the specified search criteria (i.e., exposures contained in 2 or more pointings are only counted once).

U
Total number of **unique** exposures taken with a U band filter. (note: since pointings may overlap, this number may be less than the sum of the entrees listed in the "U" column of the pointings search results table).

B
Total number of **unique** exposures taken with a B band filter. (note: since pointings may overlap, this number may be less than the sum of the entrees listed in the "B" column of the pointings search results table).

V
Total number of **unique** exposures taken with a V band filter. (note: since pointings may overlap, this number may be less than the sum of the entrees listed in the "V" column of the pointings search results table).

R
Total number of **unique** exposures taken with a R band filter. (note: since pointings may overlap, this number may be less than the sum of the entrees listed in the "R" column of the pointings search results table).

I
Total number of **unique** exposures taken with a I band filter. (note: since pointings may overlap, this number may be less than the sum of the entrees listed in the "I" column of the pointings search results table).

Line
Total number of **unique** exposures taken with a Narrow band filter (note: since pointings may overlap, this number may be less than the sum of the entrees listed in the "Line" column of the pointings search results table).

Other
Total number of **unique** exposures taken with any filter or filter combination not explicity assigned to a band. (note: since pointings may overlap, this number may be less than the sum of the entrees listed in the "Other" column of the pointings search results table).

Exposure Display Format
Clicking on the filter totals in the summary table will run a script to display the unique exposures for that particular filter and selected search criteria. The default **"retrieval list"** format will display data set names in an html table with options for downloading files. The **"print list"** option displays a comma-separated list of data set names which can be cut and pasted into other data retrieval tools. The **"file list"** option writes the list of data set names (one per line) to a file (dsn.txt) which can be downloaded to the users computer.

Maximum Number of Exposures Displayed
The maximum number of rows (i.e., exposures) to be displayed on the exposure search results page. Allowed values are 50, 100, 500, 1000, and 5000. The default is 100. Note displaying a large number of rows will increase execution time and displaying a large number of buttons may cause some browsers problems.

Found Pointings Table

Each row of the pointings table contains information on the exposures within one pointing. The non-zero "U", "B", "V", "R", "I", "LINE", or "OTHER" filter entries contain two numbers: the total number of exposures taken with a given filter (upper number), and the sum of the exposure times for those exposures in seconds (lower number). Clicking on the upper number will display the exposures table (see below). The pointings table column headings are described below.

Mission/Instrument
The mission and/or instrument from which the data are derived. The table entries will be linked to the appropriate MAST mission home page. Currently only information concerning HST/WFPC2 pointings are avaiable in the pointings table.

RA (2000), Dec (2000)
The right ascension and declination in J2000 epoch as defined for a particular pointing.

Galatic Latitude and Longitude
The galactic latitude and longitude as listed in the pointings table, as calculated from the J2000 ra and dec in the mission catalog.

Ecliptic Latitude and Longitude
The ecliptic latitude and longitude as listed in the pointings table, as calculated from the J2000 ra and dec in the mission catalog.

Angular Separation
When performing equatorial coordinate searches, the angular separation (radius), given in arcminutes, between the SIMBAD (or NED) coordinates and the coordinates listed in the pointings table.

Total
Total number of exposures counted for the pointing.

U
Total number of exposures taken with "U band filters" counted for the pointing.
B
Total number of exposures taken with "B band filters" counted for the pointing.
V
Total number of exposures taken with "V band filters" counted for the pointing.
R
Total number of exposures taken with "R band filters" counted for the pointing.
I
Total number of exposures taken with "I band filters" counted for the pointing.
Other
Total number of exposures taken with any other filter or filter combination for this pointing.
Line
Total number of exposures taken with "Narrow band filters" counted for the pointing.
Unique
Total number of unique bands within this pointing.
First Date
The date of observation the earliest exposure for this pointing was acquired.
Last Date
The date of observation the latest exposure for this pointing was acquired.

Exposures Table

This table lists the individual exposures and data set names associated with the pointings selected from the pointings search results page. Options on the search results page control both the page format (i.e., html table or comma-separated list), and the maximum number of entries displayed. The html table format allows the display of preview images and data retrieval. Column headings are described below.

Row
The row number in the results.

Mark
Mark this dataset for retrieval by pressing this checkbox. After you have marked for retrieval all the datasets that you're interested in, hit the **Retrieve Marked Datasets for Retrieval** button to initiate the retrieval.

Dataset Name
The unique identifier for an HST observation. This value is hyperlinked. By clicking on it, you can display a preview image of the observation.

Target
The name of the target of the observation, as given by the proposer.

PEP ID
The ID number of the observing program. Clicking on an entry in this field will display the HST proposal search page containing the proposal title, PI's name, abstract, ads links to published papers, and a table of all known observations.

Occasionally, you will see target names like `PAR`, `UNKNOWN-TARGET`, and so on; these are (most likely) parallel observations, which are observations done by one instrument while another is making the primary observing of the telescope's visit.

RA
The equatorial right ascension of the instrument aperture, in equinox J2000.

(For the WFPC2, the aperture right ascension coincides with the V1 right ascension, which is the middle of the field of view.)

Dec
The equatorial declination of the instrument aperture, in equinox J2000.

(For the WFPC2, the aperture declination coincides with the V1 declination, which is the middle of the field of view.)

V3 Position Angle
The V3 position angle (PA_V3) is the direction in degrees east from north that the tip of the L shape formed by the 3 WF chips would point, if the L shape is imagined to form the tip of an arrow. (see WFPC2 Position & Orientation). The V3 position angle is 180 degrees different (exactly opposite in direction) rom the U3 position angle, which is specified by the observer during the Phase 2 proposal process as the "ORIENT".

Exposure Time
The exposure time of the observation, in seconds.

Filter
The HST filter used for the observation.

Observation Date
The starting date and time of the observation (GMT).

Release Date
HST data has a nominal proprietary period of one year (though in special cases, this may be shortened or extended). The Release Date field gives the end of the dataset's proprietary period.

Overview of On-the-Fly Reprocessing

Introduction

The On-The-Fly Reprocessing (OTFR) system reconstructs FITS data files from original telemetry and calibrates data at the time that a user's request for the data is processed. Through this system, users obtain data calibrated with up-to-date reference files, parameters, and software. Only the telemetry files (called POD files) need to be stored for instruments supported by OTFR, although we will still store the initial versions of the raw data files. Since the summer of 2000, the only calibrated STIS and WFPC2 data available has been OTFC STIS and WFPC2 data. The On-The-Fly Reprocessing system, released March, 2001 for STIS and WFPC2 and September 26, 2001 for NICMOS, will eventually provide the calibrated data for all future instruments, including ACS and COS.

An OTFC system was developed for HST data by the CADC/ST-ECF (Crabtree et al 1996).

Advantages of OTFC / OFTR

By deploying OTFC and later OFTR, we only need to store the uncalibrated data (or in the case of OTFR, the original telemetry) in the HST archive. Doing so significantly reduced the volume of data stored in the archive (Hanisch et al 1997). For WFPC2, we achieved a savings in storage space by more than a factor of ten. The raw data occupies less storage and compresses much better than the calibrated data. The storage requirements for the HST archive have rapidly increased with STIS and NICMOS and will become even greater with the Advanced Camera (ACS). The large advantages of OTFC/OTFR for WFPC2 will likely be realized for ACS. We no longer store the original calibrated data for WFPC2 and STIS as of summer 2000.

Another motivation comes from the scientific need to recalibrate data to take advantage of various improvements. A large fraction (over 90%) of the calibrated data in the HST archive could be improved by recalibration, although the improvements are not always significant. In the past, instruments that undergo evolution of calibration files or calibration software often required that users carry out their own recalibrations at their home sites. With OTFR, the STScI carries out the recalibration.

The elements for improved calibrations are listed below.

- Improved calibration files. For example, the ideal dark current reference files for correcting WFPC2 observations are those that are obtained at nearly the same time as the science data. Therefore, the original calibration, using nominal dark reference files, is not optimal. The OTFR system helps solve this problem by permitting users to obtain the calibrated data with the appropriate dark file as soon as it is available. In addition, other types of improved calibration files are sometimes generated that supersede previous calibration files. Such files are used by OTFR soon after they are created.
- Improved parameter values. Improvements to the data can come about as better values for header keyword parameters are determined by the instrument teams. The OTFR system incorporates the improved header structure in a clean way.
- Improved software. Improvements are made to the calibration software (e.g., calwp2 and calstis) to correct problems, improve algorithms, or add new capabilities.
- Handling associations. OTFC had no clean method to handel associations of data files such as those generated for NICMOS or ACS. OTFR will generate associated data products in the indentical process as the OPUS pipeline with no need to invent new tools.

Dataflow

In broad outline, the following steps are carried out.

- A user specifies the desired calibrated datasets through the usual retrieval mechanisms in Starview or the archive Web interface. The user is informed of the initial status by email.
- The relevant POD files are retrieved from the HST archive and passed to the OTFR system.
- The raw FITS files are constructed from the telemetry (POD files).
- The headers are updated with the best values of calibration files, calibration switches, and other parameters.
- The data are calibrated.
- The data are sent back to the HST archive system.
- The HST archive system returns the data to the user.
- The HST archive system sends a final email message about the completion status to the user.

Elements of the OTFR System

- **User interfaces**

  Starview, the user interface to the STScI archive, provides capabilities for requesting OTFR processing (Travisano and Richon 1997). The STScI archive Web interface to the archive may also be used to retrieve OTFR data. StarView currently is the only archive interface which allows the user to review the details of the OTFR changes and reference file updates, by employing the WFPC2 OTFR or STIS OTFR screens.

- **Data Archiving and Distribution System (DADS)**

  DADS, the STScI data archive system, provides raw data to the OTFC pipeline (Travisano and Richon 1997). DADS also sends the newly calibrated and raw data to users. Future versions of DADS will allow users to specify either calibrated or updated raw data alone.

- **Calibration Database System (CDBS)**

  The calibration database system tracks all calibration files used for calibrating HST data (Lubow et al 1997). The system contains a tool called bestref that recommends the calibration files for each existing dataset. These recommendations are updated as new calibration files become available.

- **Calibration Software**

  The calxxx software is used to calibrate the data. It is provided through STSDAS.

- **OPUS**

  To coordinate the processing activities, the OTFC system employs OPUS blackboards (Rose 1998). They allow for parallel processing of tasks distributed over multiple CPUs. The OPUS system operates by means of scripts that transfer the data from the archive system, perform the getref/upref processing, the actual calibration processing, and the return of the data to the HST archive system.

Instructions for Using On-the-Fly Reprocessing (OTFR)

- OTFR is currently available for WFPC2, NICMOS, and STIS data. In fact, the ***only*** source of calibrated data for these instruments is OTFR.
- Both the Web interface and Starview provide access to OTFR.
  - On the Web interface, you will find the Science Files Requested box on the Retrieval Options screen. To retrieve OTFR calibrated data check Raw and Calibrated data.
  - On Starview, make the request as you normally would. On the Retrieval Request - File Options screen, you will find a check box for Raw and Calibrated data.

    More detailed information about each dataset is found by going to the HST Instrument Searches screen from the Starview Search Menu. From there, select on the OTFR menu option for the appropriate instrument search. The OTFR screen contains some new fields. The date of last software change is the most recent date of installation of new calibration software which will likely have a significant impact on the results of calibration. The date of last action update is the date of the last change of parameters for the dataset that could affect the results of calibration. You can use this information to determine whether there is any benefit in re-requesting a dataset from OTFR. If the dataset you have already obtained from OTFR was processed after both dates, then there is likely to be no significant advantage in requesting the dataset again.

- If your calibrated data request includes instruments which are not supported by OTFR, the system will automatically split your request into two requests - one for OTFR supported instruments (WFPC2, NICMOS, and STIS) and the other for nonOTFR supported instruments. You will receive separate email messages about the status of each request. The OTFR request number is terminated by the character z.

  For mixed OTFR and nonOTFR data in the same calibrated data request,

- All requests for calibrated data currently return both uncalibrated and calibrated data. In a future release, we intend to allow users the option of selecting the type of data that they receive.
- If a requested dataset cannot be calibrated by OTFR, the system attempts to return the uncalibrated data (with any modifications) back to the user.
- If you receive an email response message that says "File not processed", there was likely a temporary hardware problem during the request processing. Please resubmit the request.
- If you encounter a problem, please check the OTFR Web page to see if it has been reported.
- New problems should be reported to archive@stsci.edu

On-the-Fly Reprocessing of HST Data

Welcome to the STScI OTFR WWW site.

Through OTFR, Hubble archive users can obtain data that are processed with the latest calibration files, software, and data parameters. The OTFR system reconstructs the data files with update headers and calibrates data when processing a user's request for the data from the archive. WFPC2, NICMOS, and STIS data can now be retrieved with OTFR system.

The raw data returned to users through OTFR is reconstructed from telemetry files to include updates to data parameters.

FAQ Help

Overview

Welcome to the MAST Frequently Asked Question (FAQ) help page. If you don't see an answer to your question, or have suggestions for adding new FAQs, please contact the archive help desk at the e-mail address shown at the bottom right of this page.

The FAQ links on the various mission pages will display all the FAQs specific to that mission. A form shown at the top of the FAQ page however will allow FAQs from other missions and/or specific categories to be displayed. To use the form, simply select the mission and/or category from the menu list and click "GO".

Mission/Category

This entry specifies the mission for which to view FAQs. Note that for some missions, the MAST pages simply link to FAQ pages maintained at remote sites and will therefore have a different appearance and format. This currently applies to FUSE, VLA-FIRST, and ROSAT. MAST FAQs currently exist for the remaining MAST-supported missions. A general FAQ page also exists for MAST itself.

If a category follows the mission name separated by a "/", only the FAQ's for that particular category will be displayed. If only the mission name is selected, all the missions FAQs will be displayed.

IUEDAC IDL-Based FITS Routines

This document is intended to provide a description of the options available for reading/writing IUE data with IDL-based IUEDAC (formally IUERDAF) software. This document includes the following sections:

(For a list of acronym definitions click here.)

I. Introduction

A. History

The IUE mission had a long life time, starting from a era before the exchange of astronomical data in FITS format became a standard and extending to times of rapid development of computer power and numerical analysis techniques. Such factors required the development of two data processing packages, the first, IUESIPS, for data reduction following the observations, and NEWSIPS, for final archiving of the data at the close of the mission. The NEWSIPS-generated data products are to be preferred, but MAST will continue also to support analysis of the corresponding IUESIPS data.

The initial writing of IUE data in IUESIPS were done in "GO format," a protocol based on the VICAR file format system (see "Original IUE VICAR Label") used by the instrument development team at RAL and adopted for the IUE project. VICAR data consists of headers written in EBCDIC and binary and data in binary and required VICAR-specific software to read them. IUEDAC programs were written in IDL for convenient reading of archived VICAR files and for manipulating the IUE data arrays in the IDL environment.

Historically, most astronomers used IUEDAC software to read IUESIPS data; a very few users developed their own software). The use of FITS formats in NEWSIPS permitted a wider range of options. For example, several IUE data- reading tasks became available in the European package MIDAS. More recently, the IRAF/STSDAS group has written generalized FITS table-reading tasks which can be used for reading of IUE data as well as a 'iuetools' package which permits the selection of specific extracted arrays from MXLO/MXLO FITS files. The output files can then be read by standard IRAF and STSDAS tasks; see the companion document "reading IUE data files in IRAF/STSDAS."

B. Conversion from GO to RDAF format

One may convert IUESIPS GO files to "RDAF" format (*.lab and *.dat file pairs) by invoking iue IUEDAC routine,'gotordaf'. (Then one can read them by invoking 'iuespec'.)

C. Types of Data Format

The following FITS file types are used for IUE data files: p>

- a Primary Array format for IUE *raw* and *science image* files,
- Image Extension for *error flag* and *cosmic ray* images associated with the image files.
- the Binary Table Extension FITS format for *extracted spectral files* (these files contain a primary header but no primary data array; each table extension contains both a header and data array),

FITS table and image formats have been the basis for developing various programs listed below. Note also that the same file format is assumed for both tape and disk files. Thus, disk files are not separated into separate header and data files.

D. Other Documentation

The reader may wish to consult the following documentation:

- HST Data Handbook, Vol. 1., Chapter 2.2: "FITS File Format". Description of FITS primary, image and table extension arrays, and syntax for use in STSDAS/TABLES tasks.
- IUEDAC User's Guide: Chapter 3
- NEWSIPS Image Processing Manual, Chapter 12: "Final Data Products". Complete description of data file structures and contents.
- Primer on IDL structures.
- Prolog (description, caveats, and detailed examples for IUEDAC programs.
- HEASARC web page pointing to various FITS i/o libraries. This contains many IDL FITS-readers not included in the IUEDAC library.
- Evaluation of various FITS i/o tools in the IDL Astronomy Library. This source lists strengths and drawbacks of each tool considered for specific situations.

II. Caveats

A. Use of IDL for running IUEDAC routines

Because IUEDAC routines are written in IDL, the user must have IDL (licensed by RSI) on his/her computer. IUEDAC routines generally run on IDL versions 3-5 and have been modified to comply with Y2K dates. IUEDAC was written in a Unix environment, but it is also supported in VMS, MS windows, and MacOs.

B. Running the routines in the VMS Operating System

A few comments should be made regarding the use of FITS disk files on VMS computers. First, VMS does not support IEEE floating point format. Although routines are available for converting IEEE format to VMS format, some IEEE special values exist which have no counterpart under VMS. (The typical solution is to run a routine to find the special characters and then prompt the user for a replacement value.) IUEDAC software calls a routine which converts the IEEE special characters to -999.9 (although it may not flag all the allowed special characters). Second, when files are transferred from Unix to vms systems using FTP (using binary mode), the result is usually a 512-byte fixed-length record file. These files must then be either converted to 2880-byte fixed-length record files, or read using RMS block mode which ignores all file attributes. The IUEDAC FITS routines typically use the RMS-block mode for reading FITS files, while the writing routines generate 2880-byte fixed length records.

III. Examples

Examples of how to use the existing IDL routines are included below. With the exception of the IUESIPS-specific reader "extfits.pro" noted below, IDL FITS-reading routines convert the FITS headers into IDL string arrays, and the data into IDL variables. When reading FITS files containing one or more extensions, the user must specify which data is to be extracted. *Be sure that FITS files have been transferred properly! (e.g. by first typing "binary" in the ftp process.)*

A. Reading and Interpreting FITS Files:

1. Displaying contents of FITS files, IUEFHRD.pro To display the format of an unknown FITS file called guess.fit: Write the primary header as "mhead", the first extension header (if it exists) as "exthead", and the starting record number of each header and data section found in a vector called "params":

   ```
   iuefhrd,'guess.fit',params,mhead,exthead
   ```

2. A generalized FITS reader, IFITSRD.pro (see also Section IV)

   a. To read headers and primary array file arr.fit: Store main header in string array "mheader", extension header in "exheader" and primary data array as "arr":

   ```
   IDL>  ifitsrd,'arr.fit',-1,mheader,exheader,arr       ; read primary array
   ```

   b. To read headers and image extension data as eps from same file:

   ```
   IDL>  ifitsrd,'arr.fit',0,mheader,exheader,eps       ; read image extension
   ```

   In general, 'ifitsrd' calls 'iuefhrd', which lists all the parameter fields in the binary table (this may be as many as 20, but is usually less than this). Including even one of the p-fields (e.g. "p1") in the command will resulting in a listing of all these fields. Thus the action of reading the file will give the user the correspondence between the p-fields and the arrays or scalar values they represent.

   c. Reading of data arrays.

   Assume "guess.fit" has a primary array, an image extension and a binary table extension. Write the headers and the first 5 columns from the first 2 rows of the binary table, assuming the binary extension data starts in record 12:

   ```
   IDL>  ifitsrd,'guess.fit',[1,2],mhead,exhead,p1,p2,p3,p4,p5,erec=12
   ```

   Note that one uses "ifitsrd" for either for image (SILO/SIHI) or extracted data files. Because "ifitsrd" is a generalized reader, it addresses arrays by their running row numbers.

3. FITS-reader for NEWSIPS extracted spectral data arrays, READMX.pro "readmx" reads IUE merged extracted spectra (MXLO, MXHI) and returns the primary FITS header, wavelengths and absolute fluxes. The nu flags, net, background, and ripple-corrected fluxes may be optionally returned.

   a. To read a low-dispersion image:

   ```
   IDL> readmx,'swp32525.mxlo',main,wave,flux,flags,sigma,bkgrd,net
   ```

   b. To read the region of a high dispersion spectrum contiaining MgII:

   ```
   IDL> readmx,'lwp12345.mxhi',head,wave,flux,quality,sigma,wrange=[2790,2810]
   ```

   c. To read echelle orders 100--103 of this image:

   ```
   IDL> readmx,'lwp12345.mxhi',h,wave,flux,quality,sigma,orange=[100,103]
   ```

   Notice that because "readmx" is written for IUE data, it recognizes echelle orders or wavelengths rather than row numbers.

B. Writing FITS Files

These routines write FITS files from string arrays (headers) and variables (data arrays) brought into the user's IDL memory buffer by previous read commands. Both IUESIPS= and NEWSIPS-generated data may be written.

1. To generate a FITS primary array file called arr.fit from an IDL variable ARR:

   ```
   IDL>  arr = indgen(3,4,5)         ; IDL variable
   IDL>  keygen,arr,header,in='data'         ; generate FITS keywords
   IDL>  hdugen,header,arr,fname='arr.fit'         ; create primary array file
   ```

2. To append a variable "eps" as an image extension to the above file:

   ```
   IDL>  keygen,eps,epshd,in='data'         ; create header for eps array
   IDL>  imxgen,'arr.fit',epshd,eps         ; append to arr.fit
   ```

3. Writing IDL variables to a binary table extension file with IFITSWRT,pro.

   a. To write W,F,NU, and SIGMA vectors to a FITS binary table file called 'data.fits' (default name) using the string array HDR as the primary array, and defining TTYPE and TUNIT keywords:

   ```
   IDL>  ifitswrt,hdr,w,f,nu,sigma,p1t='wavelength',p1u='angstrom', $

             p2t='flux',p2u='ergs/cm2/sec/A',p3t='quality',p4t='sigmas'
   ```

   b. Write X and Y vectors to a FITS (binary table) file called "gauss.fits" (no header array exists):

   ```
   IDL>  ifitswrt,0,x,y,ofn='gauss.fits'
   ```

   c. Write header, wavelength, flux, and nu vectors as a binary table extension to a FITS file called "data.fits" (default name).

   ```
   IDL>  ifitswrt,hdr,w,f,nu
   ```

4. Writing IUESIPS files in GO format to FITS files

   IDL> gotordaf,`swp12345.mehi1'   ; first convert GO to rdaf-format files
   IDL> extfits,'imaget',1,3   ; here "imaget" is a root name like swp12345hlg.

   The output file will be "swp12345hlg.fits"

IV. Summary of FITS Reading and Writing Routines

A. General FITS Readers:

IFITSRD
- general FITS reader, but written with IUE data in mind. IFITSRD can read primary arrays, binary table extensions, image extensions, and ascii table extension FITS formats. The various data fields are given by a series of "p-arguments" (see Example 2c above), all of which are printed to the screen when the IFITSRD command is given. In general, one may not know what data fields these p-arguments correspond to until they are printed out. Since IFITSRD is a generalized FITS reader, these p's will differ for different types of files and, obviously, for different satellite missions. IFITSRD uses the following routines, which are also general FITS readers designed with IUE files in mind:

IUEFHRD
- reads a FITS primary and extension header. If file format unknown, run this before IFITSRD

IUEARRD
- reads FITS primary array or image extension

IUE3DRD
- reads one row of a FITS table Output is 1-20 fields (IDL variables).

IUE3DROW
- reads 1 row of a FITS table into an IDL structure

IUEATRD
- reads one row of a FITS ASCII table Output is 1-20 fields (IDL variables)

B. FITS Writers

1. General Writers:

   IFITSWRT
   - writes 1 row to a binary table extension using up to 15 input parameters. An input string array header can be specified for creating the primary FITS header. Parameters may be strings, scalars, or vectors or arrays (but currently not variable-length arrays.) Additional rows can be appended to existing binary tables.

3. Writers for IUE data:

   SAVFITS
   - writes IUE data from IDLSAV files to fits files
   IMXGEN
   - Appends input header and data to input FITS file as image extn
   HDUGEN
   - creates FITS primary array file from input IDL data and header
   MXCON
   - converts NEWSIPS MXLOs to IRAF-compatible primary FITS files. (The output file is compatible with IRAF fits readers.)

8. IUESIPS-specific FITS writers:

   IMFITS
   - specific to IUESIPS image files (RI, PI, LBL, FES) Converts images to primary array FITS images. FITS files. Using IMXGEN (see below), epsilon arrays can (optionally) be appended to PI or ELBL files as an image extension.
   EXTFITS
   - specific to IUESIPS extracted files (MELO, MEHI) Converts "lab, dat" files generated by GOTORDAF to FITS files. Output is FITS primary array or binary table extensions. Each row of the binary table denotes data for a spectral order.

9. Miscellaneous Low Level Routines:

   Routines designated with a "*" were originally borrowed from the ASTRON library and were developed by UIT, HRS and others. Most are modified forms of borrowed versions suitable for IUE data.

   ***STPAR**
   - returns the value of a FITS keyword.
   ***ADDPAR**
   - adds or modifies a FITS keyword in an IDL string array.
   ***DELPAR**
   - deletes a keyword from an IDL string array.
   ***FLAGNAN**
   - flags IEEE NaN (not a number) values
   PSTRA
   - write an IDL string array (e.g., a FITS header) into an ASCII disk file for storage or printing.
   IUEFHMOD
   - modifies a keyword in an existing FITS file.
   FITSCON
   - converts FITS binary table data types (i.e. IEEE big-indian format) to formats compatible with the current cpu.
   TRANS_BYTES
   - translates internal data formats between different machine architectures.
   SWAP_BYTES
   - low level routine for swapping bytes.
   FITSLAB
   - converts an IUE VICAR label to FITS keywords as currently planned for the IUE final archive.
   KEYGEN
   - converts the IUE scale factor record to FITS keywords, or generates the required FITS keywords necessary to describe the input data set.
   FDATE
   - converts year and cumulative day to FITS date format.
   ***DATECONV**
   - allows conversion between various date formats, including both old and new FITS date-format conventions.

10. Miscellaneous Text Files:

   The files below are FITS header files which are used by some of the FITS writing routines to create FITS headers: 3DHD1.TXT; 3DHD2.TXT; MAIN_HD.TXT; IMAGE_HD.TXT; 3DMELO.TXT; 3DMELO2.TXT; 3DMEHI.TXT; 3DMEHI2.TXT; BINHD.TXT; GENHD.TXT.

Reading/Writing IUE FITS Data in IRAF/STSDAS

I. Introduction

The original IUESIPS-generated data were archived in the Guest Observer ("GO") format, based on an obsolete version of the VICAR format. This format is not compatible with file readers supported by IRAF and STSDAS, which means that IUE data generated by IUESIPS cannot be read by them unless they are first rewritten to FITS (or ASCII) by an external package. NEWSIPS-generated files were stored as FITS binary files and can be accessed by a variety of FITS readers. However, NEWSIPS-generated files were stored in two different FITS structures, summarized as follows:

- SILO/SIHI, FES, RAW files: Stored as primary data FITS arrays, these may be read by rfits or STSDAS strfits Error-flag and cosmic-ray data are stored as image extensions in the SILO/SIHI files and can be read with ***strfits***.
- Extracted spectral files (MXLO/MXHI): Each order (1 for MXLO, about 60 for MXHI) is stored as a table row (which in turn store either 9 (MXLO) or 17 (MXHI) fields of string, integer, floating point, and vectors). These files may be read in IRAF only with the STSDAS package ***iuetools***, as described in Section III.

II. Additional Documentation

The reader may wish to consult documentation contained in the following sources:

- HST Data Handbook, Vol. 1., Chapter 2.2: "FITS File Format,",
  Description of FITS primary, image & table extension arrays, and syntax for use in STSDAS/TABLES tasks.
- IUEDAC User's Guide, Chapter 3 Working with various file formats.
- NEWSIPS Image Processing Manual, Chapter 12 ("Final Data Products"). Complete description of data file structures and contents.
- Web page pointing to various FITS i/o libraries: http://heasarc.gsfc.nasa.gov/docs/heasarc/fits/fits_libraries.html
- on line help page in ***iuetools*** of IRAF/STSDAS

III. The *iuetools* Package

In order to read MXLO/MXHI files, the user must have ***iuetools*** installed on his/her computer. This first requires IRAF version 2.11, STSDAS (version 2.0), and STSDAS/TABLES.

The ***iuetools*** package contains two tasks:

mxexpand: computes wavelength array from FITS header keywords and writes output file in form suitable for STSDAS and TABLES tasks.

mxtomultispec: extracts spectra in FITS binary tables created by ***mxexpand*** and outputs file in "multispec" (two-dimensional) format. This file can then be used in the ***onedspec*** package of IRAF/NOAO, such as ***splot***.

Notes:

1. Wavelength arrays: wavelengths in the MXLO (MXHI) order(s) are contained implicitly as header keywords, and can be expanded (calculated) into arrays via a linear dispersion relation. This calculation is the primary function of "mxexpand" task. Note that all wavelengths in NEWSIPS- generated data are monotonic as they refer to vacuum wavelengths.

2. Concatenating spectral orders: IRAF/STSDAS does not support scripts to splice MXHI orders. (To do this requires wavelength arrays and a designation of splice points. There are, however, IUEDAC routines which perform this function.) We recommend caution in writing software to merge spectral orders with a constant wavelength spacing since this requires a resampling of fluxes to a new wavelength grid.

3. Alternative to ***iuetools***: If the user does not have ***iuetools*** installed, it is possible to read NEWSIPS MXLO files in IRAF. In that case one would have to first run another program to convert the MXLO table array to a primary array. For example, if IDL is available, one may use the IUEDAC task ***mxcon*** for this FITS-to-FITS file conversion (see http://archive.stsci.edu/iue/iuedacfits.html).

IV. Examples of Use of *iuetools* Package for MXHI Files

1. Reconnoitering your MXHI file, e.g. swp56875.mxhi:

Evaluate the structure of the MXHI/MXLO file (after loading STSDAS & TABLES):

ta> **catfits swp58675.mxhi**
Output:

```
EXT#  FITSNAME       FILENAME   EXTVE DIMEN  BITPI OBJECT
 0    swp56875.mxhi                              8
 1    BINTABLE       MEHI       17Fx60R
```

Note that swp56875.mxhi is a 3-dimensional binary table with 60 rows and 17 fields. Each of these fields may be a scalar or a vector of a fixed length (from IUE image to image) and is described in the NEWSIPS NEWSIPS Image Processing Manual, Chapter 12.9 (or Chapter12.8 for the 9 fields of MXLO files). The length of the wavelength or (various) flux fields is 768. This can be verified by executing 'catfits' with the "long" keyword set to "yes" for the extension file:

ta> **catfits swp58675.mxhi[1] long=yes**

An extensive dump of the fits header is printed out. Keywords of the form TFORMxx, where xx denotes the number for the wavelength or flux fields gives the dimensionality, 768.

2. Using ***mxexpand*** for later work with STSDAS tasks:

a. Convert MXHI file to an expanded FITS table:

   ta> **mxexpand swp58675.mxhi**
   Output: ***Converted file swp56875.mxhi --> swp56875mxhi.fits***

   [Both input and output files are 3-dimensional binary tables.]

b. Evaluate the file produced by ***mxexpand***:

   ta> **catfits swp56875mxhi.fits**
   Output:

```
EXT#  FITSNAME       FILENAME   EXTVE DIMEN  BITPI OBJECT
 0    swp56875mxhi                               8
 1    BINTABLE       MEHI       18Fx60R
```

   [mxexpand has added a field of wavelength vectors; none of the old fields are deleted]

c. Create listing of header to look at column attributes

   To display column names, data type, format, and units, invoke 'tlcol' in TABLES:

   ta> **tlcol swp56875mxhi.fits[1] nlist=4** ,

   or to view labeled structure of table columns, load 'stsdas' and type:

   st> **tread swp56875mxhi.fits**

   To get out of the tread window, type "control-d" and "quit".

d. Having the column names from the last step, now make a simple plot:

   cl> **sgraph "swp56875mxhi.fits[r:order=100] wave_array abs_cal"**

   Note: [ ] syntax shows use of STSDAS selectors for FITS and TABLES files; for help go to http://ra.stsci.edu/bps/ovselector.html. For help on sgraph, click here.

   Alternatively, one can plot scalars among all the orders, e.g. order vs. starting wavelength:

   cl> **sgraph "swp56875mxhi.fits order wavelength"**

3. Use of the ***mxtomultispec*** task:

a. Convert output expanded file from MXEXPAND to multispec (.imh) format:

   ta> **mxtomultispec swp56875mxhi.fits swp56875ms**

   Output: ***The output file - swp56875ms.imh - has been written.***

   Note the result is necessarily an IRAF 2-dimensional image (imh) file. This can be checked with the command:

   cl> **imhead swp56875ms**

   Output:
   swp56875ms[768,60][real]: SWP56875_ABS_CAL6958G_R0001[1/1]

   This file may now be used with your favorite IRAF task, e.g.

   on> **splot swp56875ms[*,30]**

b. Comments:

   Note that the plot resulting from this simple command has defaulted to plotting the former columns wave_array (wavelength) vs. abs_cal (absolute flux) of order 30.

   The user may select an arbitary set of orders for the output file, e.g.

   mxtomultispec "swp56875mxhi.fits[r:order=(82:84,90)]" swp56875msabb selector syntax, including the use of quotes, (), [] symbols.)

   Let's check the structure of the new file:

   cl> **imhead swp56875msabb"**

   Output:
   swp56875msabb[768,4][real]: SWP56875_ABS_CAL6958O_R0036[1/1]

   This result tells us that we have an image containing 768 columns and 4 rows.

Contributed Data Analysis Software

- correct_astro.zip - This file contains an IDL program and auxiliary data sets produced by Derck Massa and Ed Fitzpatrick for recalibrating IUE NEWSIPS low dispersion data using HST FOS standards. The software and analysis is described in the paper "A Recalibration of IUE NEWSIPS Low-Dispersion Data", Massa, D., Fitzpatrick, E.L. 2000 ApJS, 126, 517 (2000ApJS..126..517M). Note the IDL program requires routines available from the IDL Astronomy User's Library.

This article originally appeared as a chapter by the same name in *Exploring the Universe with the IUE Satellite* (Y. Kondo, ed., D. Reidel Publishing Company (and appears here with permission of Kluwer Academic Publishers), © 1987), and has been updated for mid-1994 by Jim Caplinger.

1. Operational Concepts

The IUE mission is based on real time control of the satellite and instrument and real time acquisition of the scientific data. Thus both the spacecraft operations staff and the science users must support IUE operations 24 hours per day, every day. Operations are shared between two very similar ground systems, one of which is located in the USA and operated by NASA. The other, provided and operated by ESA, is located in Spain and is used by European observers. According to the Memorandum Of Understanding between the three agencies, NASA has use of IUE for two thirds of the time, and ESA and SERC share equally the remaining third. For the purpose of operations it was decided to divide each day into three shifts of eight hours duration, and it was agreed that the NASA ground system would control the satellite for two shifts, and the ESA ground system for one shift.

The receiving site for NASA's ground system was, until April 1986, located at the Goddard Space Flight Center (GSFC), Greenbelt, Maryland. Subsequently it has been removed to NASA's facility at Wallops Island, Virginia (WPS). NASA's spacecraft and science operations facilities have always been located at GSFC. Commands and received data are now transmitted between GSFC and WPS by a commercial communications satellite link.

NASA has three principal areas of responsibility in operations: first, overall responsibility for monitoring and maintaining the health of the spacecraft; second, providing a backup system for the purpose of spacecraft safety during the shift controlled by ESA's ground station; and third, operating IUE for two 8 hour shifts each day, designated US1 and US2. The spacecraft-related tasks are carried out on a 24 hour per day basis by the GSFC IUE Operations Control Center (IUEOCC). The scientific operations are carried out by the IUE Science Operations Center (IUESOC), also at GSFC, in conjunction with the IUEOCC. The IUESOC comprises a Telescope Operations Control Center (TOCC) from which astronomical observations are controlled during the US1 and US2 operational shifts. An Image Processing Center (IPC), located near GSFC, carries out the standard processing of the IUE data.

All the elements of ESA's ground segment are located at Villafranca del Castillo near Madrid (VILSPA). ESA provides spacecraft control and science operations for one shift, designated VILSPA, and in a second shift the standard data processing is carried out. Because the ESA station has limited backup facilities, e.g. only one computer capable of controlling IUE, GSFC maintains readiness to take control and keep the spacecraft safe in the event of a failure in the VILSPA station.

The operational concept of sharing, internationally, the responsibility for operations was made possible by the choice of a geosynchronous orbit for IUE. Constraints on the orbital parameters arose since continuous viewing of IUE is required from the NASA receiving/transmission site and for at least one shift per day IUE must be in view from VILSPA. To insure reliable communications, IUE must be at least 10° above the local horizon at VILSPA for more than about 10 hours per day, which is the time required for an 8 hour shift, a shift handover of about 30 minutes, and a monthly adjustment by 2 hours in the shift starting time. The latter arises since the orbit is fixed in sidereal time but for the convenience of the operations staff the shift start remains at a fixed Universal Time during each month.

An elliptical geosynchronous orbit was chosen with a period of 23 hours 56 minutes, eccentricity 0.2, inclined at 28° to the equatorial plane and with the ground track initially centered over the Atlantic at about 70° west longitude. With this positioning the VILSPA viewing time usually averages 12 hours. As the orbital plane precesses westward due to natural perturbations the viewing time falls and when the 10 hour minimum is reached an orbit adjustment must be made. A maximum of 15 hours may be achieved at its most easterly position. Partly in consequence of these orbit adjustments, and partly as a result of other natural perturbations the ground track of the orbit has gradually evolved during life of the mission as shown in Figure 1. For example, as of late June 1994, the eccentricity has dropped to 0.13, while the inclination has risen to 35°.

Fig. 1. The IUE Ground Track.

An early project objective was that the IUE system would be an international research facility, available to a wide community of astronomers, and be organized much in the way that many ground based observatories are operated. The operations management plan and the ground system were specifically oriented towards achieving this. IUE has been operational since its launch, 26 January 1978, for over 16 years at the time of writing. It continues to provide excellent facilities to the scientific community. It can be unequivocally stated that all scientific objectives of the mission have been met or exceeded. The mission's success was made possible not only by the outstanding performance of the spacecraft and its scientific instrumentation, but also by the excellent cooperation of the technical and scientific staff of the participating agencies. These achievements have been widely acknowledged in the general scientific community as being unique in space exploration.

2. The IUE System

The operation of IUE, like any complex scientific satellite, involves many systems. The space segment includes the spacecraft and the payload systems. The ground segment includes: the ground station which transmits commands and receives telemetry; the operations control center, housing the ground control computers used by the controllers to analyze the telemetry and issue appropriate commands; the science operations center; the data reduction system; and a communications system to link the parts together. Descriptions of some aspects of the system may be found in Boggess *et al.* 1978 and Boggess and Wilson 1987. To prepare the reader for the discussion of operations that follows, this section summarizes the main characteristics of these systems and details are given of relevant systems not adequately covered elsewhere.

2.1 The Spacecraft

The sole purpose of the spacecraft is to support the Scientific Instrument (S/I) in achieving the scientific objectives for the mission. These objectives give rise to the basic performance requirements for the spacecraft. First the satellite should be able to point the telescope anywhere within the celestial sphere except within 45° of the Sun. Second the Attitude Control System (ACS) should on command move the telescope to a new target with a slew rate of $4.5° min^{-1} axis^{-1}$ and guarantee that, at the end of the maneuver, the desired target star falls into the 16 arc minute field of view of the Fine Error Sensor (FES), a unit which performs the dual functions of star field mapping and guide star tracking.

Three-axis stabilization of IUE was initially accomplished by an Inertial Reference Assembly (IRA) composed of 6 gas bearing single-degree-of-freedom gyroscopes operated with pulse rebalance electronics. The ACS was designed to hold a 1 arc second diameter star image within a 3 arc second entrance aperture to permit an integrated exposure of at least 1 hour by the spectrograph camera. Now, under the two-gyro/Fine Sun Sensor (FSS) control system, the FSS is also used as a sensor for spacecraft control. The ACS uses the outputs of the attitude control sensors (gyros, FES, and/or FSS) as inputs to the control program in the On Board Computer (OBC). The OBC then controls the spacecraft attitude and slews by changing the rotation speed of the pitch, yaw, and roll momentum wheels.

The primary power for IUE is derived from the two solar cell arrays which are shown in the general layout, Figure 2. The power output is a function of the angle between the Sun and the satellite pointing direction (+x axis). The supplement of this angle is designated Beta. In normal operations the satellite is rolled about the x-axis to keep the Sun close to the x-z plane. Thus the single angle Beta is useful to define the approximate orientation of the satellite with respect to the Sun, and will be so used here.

Fig. 2. IUE Configuration.

Central to the spacecraft control are the command system and the data multiplexer unit (DMU). The Command Decoder receives the commands, checks for errors, and then routes valid commands or OBC data block loads to the correct subsystem. The DMU samples the performance data from the spacecraft subsystems and generates two telemetry streams: one is dedicated to the OBC and its control of the spacecraft; the other is the ground telemetry stream, which includes both the science data and the spacecraft `housekeeping' data. The OBC also uses the ground telemetry stream.

The final key spacecraft element is the communications system, which warrants description in some detail. Two wavebands, S-band and VHF, are used for communication between IUE and the ground. The normal data telemetry link from IUE to the ground receiving site is by S-band (2249.8 MHz). This telemetry can be transmitted at several different bit rates: 40, 20, 10, 5, 2.5 and 1.25 kilobits per second (kbs). There is a convolved, half rate, data mode used to increase accuracy. (The 40 and 2.5 kbs telemetry rates are not used operationally because there is either a timing conflict in the generation by the DMU of the separate ground and telemetry data streams, or the OBC has a timing conflict in reading the two data streams.) There are two telemetry streams, one special for the OBC and the other a ground telemetry stream that is also read and used by the OBC. The dedicated OBC telemetry rate is normally held at 20 kbs for smooth spacecraft control. The telemetry rates are selected by the operations controller. Both spacecraft housekeeping data and science data come down in this S-band telemetry. There are four S-band power amplifier/antenna combinations distributed around the spacecraft, only one of which can be switched on at a time. Two are at the bottom on the sun- and the anti-sun-side respectively, and two are on the satellite upper body in similar locations. As a result, no matter what the attitude orientation relative to a ground station, there is at least one S-band antenna that can be used. There are two VHF transmitters (for redundancy) that operate at 136.86 MHz for the transmission of satellite data. A VHF transmitter is used during range and range-rate operations to determine IUE's location and also under conditions when S-band is not available, such as: spacecraft to ground S-band data link problems; during eclipses because it uses less power than the S-band; and during spacecraft emergency operations. The maximum data rate of the VHF system is 5 kbs. There are two VHF command receivers (148.98 MHz) and decoders for redundancy on board IUE. The command bit rate is 0.8 kbs. All operations and control are achieved through this command system.

2.2. The Ground System

The IUE ground system serves two general functions: controlling (commanding) the spacecraft operations and payload utilization; and receiving and processing telemetry, both science data and spacecraft housekeeping data. Science data processing is also carried out by the IUE computers and various ancillary systems. On account of the separation of the control center at GSFC from the command and receiving site at WPS, a complex communications network is used when operating IUE from GSFC. The ESA facility at VILSPA is very similar functionally but simpler partly because it is all situated at one site.

At GSFC the command of IUE is initiated either in the TOCC, or in the IUEOCC. VILSPA also divides control between a main control room and the observatory room. Operations of an observatory-type satellite are very complex and are achieved for IUE by calling up a set of pre-coded and extensively tested procedures, each carrying out a particular sequence of operations, such as camera preparation, exposure and reading. The procedures are run on the control centers' computers and can check the status of the satellite via the telemetry before selecting the appropriate command and issuing it at the appropriate time. A medium level and user-tolerant language known as Control Center Interactive Language (CCIL) was developed which is used by the operations staff to develop new procedures to meet the requirements of the guest observers (GOs).

The overall ground system is designed in such a way as to resemble functionally the operations of a modern ground-based telescope. A Resident Astronomer (RA) provides the necessary support to the GO. The Experiment Display System (EDS), which consists of an interactive control keyboard and display terminal, is operated by a Telescope Operator (TO), usually working in the TOCC. These personnel, the RA and the TO, possess the required knowledge of spacecraft maneuvering, target acquisition, and S/I operations needed to advise the GO how to carry out critical operations in an efficient way. They also actually carry out the operations, since the GO is not permitted to use the control functions of the EDS console. The EDS provides the observer with all the information needed to plan maneuvers, identify the target, and verify the quality of the spectral image and carry out a `quick-look' analysis of it.

3. Normal Operations

Normal operations are described below in an ordered sequence, commencing with proposal selection and the preparations made prior to the observing shift by a guest observer who has been allocated observing time, and followed by shift handover and normal spacecraft operations. Next, instrument operations are described in the form of the sequence for a typical observation. Finally, calibration observations and routine data reduction are considered.

3.1 Proposal Selection and Observation Planning

The proposals received by the deadline towards the end of each year are reviewed by panels of peers. In the USA, the panels report to NASA Headquarters which makes the final approval of shift allocations. In Europe, ESA and SERC at first allocated their shares separately, but following an agreement reached in 1981, a single joint allocation committee (of peers) selects the proposals and determines the shift allocation. Allocations for collaborative proposals which require both US and VILSPA time are negotiated between the three agencies. An annual schedule commencing in July is prepared from the selected programs, and these form IUE's observing years or observing episodes as they are known in the USA. The detailed schedule for a given month, however, is usually prepared only a month or two in advance to give observers as much time as possible to incorporate their research into their observing plans and change their plans as needed.

Once a GO is granted observing time with IUE, usually in the form of a number of 8 hour shifts, all targets specified in his or her proposal will be checked against Sun, Earth, Moon, spacecraft power, and thermal constraints in order to investigate target availability throughout the year. This information, combined with any time-dependent requirements specified by the GO, is used by the two ground stations to construct the schedules that assign GOs to specific shifts. In due time the GOs are contacted to carry out their observations. On arrival for his or her observing shifts the GO makes final preparations with the aid of an observatory RA, who checks the overall plan for the shift, in order to confirm the feasibility of the proposed observations, prepare any special procedures required, and establish whether suitable finder charts are available for star identification, etc.

If the GO already has some observing experience with IUE and the RA approves, the GO may carry out the observations in either a `remote' or `service' observing mode, in which case he or she does not need to be present at the ground station for the observations. In both cases, the TOCC staff keep in contact with the GO either by phone or over the computer networks as needed. Remote observers receive the raw data over the network and can display it using software similar to that used by the TOs to carry out their quick-look analysis, although they do not have the observatory's software to carry out the data reduction. (They may well have their own software to carry out the reduction themselves, however.) Service observers are not interested in looking at the raw data, and so do not need to have any special software.

3.2 Shift Handover and Spacecraft Operations

In the case of a transatlantic handover, the station assuming control will already be monitoring the spacecraft's telemetry and displaying its status when, about 30 minutes before handover is due, verbal contact is made between the control centers and details are passed to enable detailed planning of operations to commence. Handover itself is marked by the relinquishing station sending a command to change a telemetry bit that then indicates the other station has control.

Routine spacecraft operations include: maintaining communications with the spacecraft, principally by switching S-band antennas and sometimes adjusting the data rate; monitoring all spacecraft housekeeping data against given safety or operational limits for each system, carrying out corrective action when necessary, e.g. slewing to a power positive attitude to prevent excessive battery discharge; planning and execution of maneuvers ensuring pointing constraints will not be violated; correction of gyro drift using information from the FES; dumping of angular momentum by means of the hydrazine jets when the speed of a momentum wheel is too high; and recording processed telemetry data and its analysis for spacecraft trends. In addition, many of the problems described in Section 5, and the testing of new operating procedures give rise to new routine operational requirements. Finally, the operations team must always be prepared, in the event of an emergency, to take immediate action to insure spacecraft safety pending a more detailed analysis by the relevant experts.

3.3 A Typical Observation

The sequence of operations for a typical observation is as follows. The coördinates of the desired target are entered into the ground computer's maneuver generator which offers the operator the choice of several different maneuver sequences to reach the target. The operator selects one, configures the spacecraft appropriately and sends the maneuver command. On completion of the slew to the new target, the field of the FES is transmitted to the ground and displayed on the EDS, the target is identified by the observer, and IUE is moved to place the target in the required spectrograph entrance aperture. Next it is confirmed that the S/I is in the required observing mode. Then, assuming that the camera has already been prepared, an exposure may be started. During the exposure a camera in the other spectrograph can have its image read out, transmitted to ground and it can then be prepared for the next observation. At the end of the exposure the observer can choose to read out the image immediately, or, alternatively, he or she can commence the next operation without seeing the image and arrange for it to be read out later during an exposure with the other spectrograph or even during the slew to the next target. (This last option is not usually recommended as contamination of the image data frequently results.) The observer, with the help of a skilled RA to advise, can get the maximum from an 8 hour shift by planning carefully the sequence of targets in order to minimize slewing time, and also by performing camera preparation and readout during other operations if possible. This is especially important when the observer requires short exposures on several targets. Although a shift is planned in advance, many decisions have to be made on the spot. For example, there is in general no attempt made to coördinate the attitude at handover from one station (or observer) to the next, so the observer's choice of the first target in a shift is often made only 30 minutes before shift handover when the expected spacecraft position becomes known. (This lack of coördination allows the greatest possible flexibility in scheduling shifts among different observers, since otherwise a change in one observer's schedule would adversely affect the schedules of several other observers.)

The commands to generate these operations are transmitted from the ground by running procedures in the ground station's computer with appropriate parameters. The options available are described in more detail below.

3.3.1. Target Identification and Acquisition

Located at the focal plane of the telescope, the FES, in its mapping mode, provides an image of a 16 arc minute field of stars down to V = 14 mag. This has a dual role. First it serves a spacecraft function; identification of a star with known celestial position which can be used to update the ACS to remove the errors in position introduced by a slew. Second it serves the astronomical function of a finder field in which, if bright enough, the target star can be identified and moved to the appropriate entrance aperture of the spectrograph. For fainter targets a blind offset can be made from a brighter nearby object using offset coördinates prepared in advance from Schmidt sky survey or astrographic plates. The FES has an additional function during exposure since it can be used in a tracking mode to follow a field star and provide a fine guidance signal. This is essential for long exposures to avoid movement of the target star from the spectrograph aperture as a result of gyro drift or thermally induced flexure of the telescope tube. The operations of the FES are controlled by using the appropriate procedure. All this is done by the observatory staff. The only related responsibility of the observer, but an essential one, is to provide a finder map at an appropriate scale, usually reproduced from Schmidt sky survey plates, and to identify the target. Both stations also have software that allows them to display fields based on the

Hubble Guide Star Catalog, which, since the whole sky is instantly accessible in this manner, has substantially increased operational efficiency.

3.3.2 Telescope Focus

The temperature of the structure of the telescope tube determines the separation of the primary and secondary mirrors and thus affects the focus of the telescope. It is possible to use a mechanism to refocus but this was only used for the initial adjustment in orbit. Thereafter the mechanism has not been used because it is not redundant and any failure in an out-of-focus position would reduce the quality of the data. Instead, the operators keep the telescope in focus by thermal control, achieved by switching heaters on and off at the back of the primary mirror and on the camera deck, following procedures established during the commissioning phase.

3.3.3 Spectrograph Modes

The spectrograph is configured for the observation mainly by operating mechanisms, of which the principal ones, duplicated in each spectrograph, are the high/low dispersion selection mirror, the shutter for the large entrance aperture, and the prime/redundant camera select mirror. Special procedures are used for taking wavelength calibration images, which operate the sun shutter to move a prism reflecting the calibration lamp into the apertures, and for taking flat field images from the UV flood lamps, which require special sequences to insure they strike and warm up reliably.

3.3.4 Camera Operations

Camera operations are normally made very simple through use of CCIL procedures which carry out complex sequences involving 8 electrode voltages, scanning sequences, and checking for anomalous conditions that could lead to loss of image data or, worse, damage to a camera. For example, a single procedure call can carry out a timed exposure. Another carries out a read of the image, transmitting it to the ground computer, then automatically prepares the TV tube's SEC target by erasing the residuals from the previous image and establishing the correct bias voltage on the target for optimum performance on the next astronomical exposure.

As the target is read out the data are transmitted immediately to the ground and, shortly after completion of the whole read, a copy of the resulting image is transmitted from the control center computer to the EDS in the TOCC. There it can be examined by the observer using simple image processing facilities. The most important aspect of such examination is usually an assessment of the level of the exposure. Due to the restricted dynamic range of the SEC vidicon and the wide range of intensities present in many spectra, a repeat observation with a different exposure time may sometimes be necessary. Within 15 minutes of the termination of an exposure the observer can make a decision on the subsequent program based on a quick evaluation of the image. This time is not always wasted, since an exposure in another mode may have already been initiated on the same target, or, when it is clear that a repeat is unlikely, a new target slewed to and another observation started. In camera operations, as in planning of slewing, an efficient observer can optimize the scientific return from an 8 hour shift.

3.4. Calibration Observations

The RAs perform routine observations for the calibration of IUE. Regular images of the wavelength calibration lamp are used in the data reduction process to define the wavelength scale. The camera flat fields are monitored and occasionally some shifts are devoted to acquiring a set of images of the UV flood lamp in order to construct a new Intensity Transfer Function (ITF). The observation of a set of standard stars is regularly carried out to provide data for the absolute calibration of the fluxes measured by IUE and to monitor changes in the overall system sensitivity (see Harris and Sonneborn 1987). Other calibrations, e.g. FES photometric calibration, can be carried out using the data acquired during the GO programs. These astronomical calibrations, spacecraft engineering calibrations, and testing of new procedures are carried out during specific maintenance shifts which amount to about 8% of all the available shifts.

3.5 Data Reduction

The IUE Spectral Image processing System (IUESIPS) is used to reduce the data acquired into products that are usable by the GO and are suitable for archiving for future use by other interested astronomers. The input to IUESIPS is the raw image data that results from the initial stage of image reconstitution performed on the incoming telemetry by the computer supporting operations. The prime scientific purpose of IUESIPS is to produce data that are as free as possible from instrumental effects. This is accomplished by image processing staff using a VAX workstation and associated peripherals. The processing operations include: an implicit compensation for geometric distortion of the camera system; photometric correction of the images using pixel-by-pixel ITFs; fitting of the spectral orders to a spectral format template and extraction of the spectrum; application of intensity calibrations derived from observations of standard stars; and various optional procedures. The principal data product that is delivered to the GO and transmitted to the archives, is a magnetic tape containing the raw data image and the various stages of reduction to a calibrated spectrum.

Each ground station has to keep up with the continuing daily flow of raw data images without incurring an ever-increasing backlog. The goal is to give the GO a data tape within 24 hours of the observations, prior to departure for his or her home institution. For GSFC IUESIPS runs on a VAX workstation which receives the image data via an archive tape from the commanding ground computer. At VILSPA there is only one computer for both operations and data reduction, so the latter is carried out during the US shifts following the VILSPA observing shift.

Over the many years of the mission, various aspects of the IUESIPS reduction have been changed to take advantage of new algorithms or to calibrate changing properties in the detectors. An unfortunate consequence is that a spectrum taken early in the mission cannot be directly compared with a recent spectrum of the same target, unless both have been specifically processed using the same routines. To remedy this problem, and to make the data more readily available to the astronomical community, the staffs at both GSFC and VILSPA have undertaken to develop a data reduction system, NEWSIPS (NEW Spectral Image Processing System), which uses new algorithms and re-derived calibrations to process the voluminous data taken by IUE. All images will be processed with the same routines to create a `Final Archive' of IUE data, making direct comparisons easier for observations of the same target. Among the many additional benefits of the Final Archive are a reduction in the noise level present in many spectra, an error estimate for each extracted point in the spectrum, and more accurate relative and absolute calibrations. As of mid-1994, the algorithms for high dispersion spectra are nearing completion, while those for low dispersion are complete and are being used to process the archival SWP spectra.

4. Spacecraft Operational Constraints

Constraints have to be placed on IUE operations for a number of reasons. Many of these result in restrictions, often contradictory, on pointing. Since these generally have a significant impact on the user, they are explained in detail below. Numerous others exist mostly directed towards maximizing the useful life of IUE's subsystems, either by minimizing wear, or by avoiding risky situations. Some constraints are programed into the ground computers so that they cannot be inadvertently violated by ground station personnel.

4.1. Sun, Earth and Moon Constraints

The only celestial body that IUE is absolutely forbidden to view is the Sun, which would damage the detectors and the mirror coatings, and heat the focal plane. There is a sun shutter which should automatically close if sunlight enters the telescope tube, but it is only intended as a `last ditch' safety device in the event of a failure elsewhere. In fact, IUE is not designed to operate closer than 45° to the Sun (Beta = 135°), beyond which sunlight would enter directly into the sun shield. Prior to the failure of the fourth gyro (see Section 5.1) it was permissible to go to Beta = 0°, i.e., the anti-sun direction, but with the two-gyro/FSS system, Beta > 28° must be maintained so that the FSS can play its role in controlling the satellite.

IUE can be, and has been, pointed at the Earth and the Moon, but as far as normal operations are concerned these bodies are considered to form constrained zones as they obscure a part of the celestial sphere. Furthermore they produce a high background in the FES due to scattered light within about 10° of the sunlit limb. Unlike the Sun constraint these are not hard coded into the maneuver generator and so may be overridden.

4.2. Eclipses

One unavoidable constraint arising from the choice of orbit is that IUE experiences twice yearly seasons of solar eclipses caused by the Earth. This season of intermittent Earth shadow lasts from some 23 to 26 days, and during each season a daily eclipse occurs that varies from a few minutes partial eclipse up to 80 minutes total eclipse. During total eclipses the solar cells deliver no power and so IUE must operate from its batteries alone. To prevent excessive discharge of the batteries, operational constraints are imposed which restrict the collection of scientific data. There are adjustments to the shift times to share the burden of lost time between GSFC and VILSPA and to minimize the overall inconvenience. The annual shadow seasons are designated Winter and Summer, which occur during January/February and July/August respectively. The Summer eclipses are longer and deeper. While the first objective during eclipse is to maintain command and housekeeping telemetry contact, it has to be done in the least power-consuming manner possible. There are a set of flight operations directives (FODs) for use during eclipses which define various satellite configurations that progressively consume less power. These are employed as required to insure that the maximum planned depth of discharge of the batteries is not exceeded, but always keeping in view the goal of minimizing attitude disorientation, so that recovery time for science operations at the end of the eclipse is minimized. One power conservation measure that is adopted is to switch the telemetry downlink to VHF during deep shadow since VHF uses less power than S-band. Plans for shadow operations are made using predictions provided to the IUEOCC by the Flight Dynamics Group at GSFC. In addition to solar eclipses caused by the Earth, the Moon also eclipses the Sun. However these tend to be brief, partial eclipses and early in the mission did not require spacecraft reconfiguration. The two-gyro/FSS uses the Sun as one input to the control system, so all eclipses now require special spacecraft control configurations which use only the FES and gyros.

4.3. Spacecraft Power

Figure 3 shows how the solar array power output has changed with time due to the degradation of the solar cells in their radiation environment; such degradation was, of course, anticipated and its effects planned for. To insure long battery life it is essential that IUE is at a power positive attitude for nearly all the time, except for the unavoidable eclipses described above. At launch, the IUE power requirements were about 180 W, but at the time of writing with the two-gyro/FSS mode of operation in use (see Section 5.1), the requirement is between 131 W and 154 W, depending on the nature of the operations taking place. In February 1994, the power positive region was in the range 40° < Beta < 101° for the higher power requirement, while the range was 28° < Beta < 122° for the lower power level. These regions are narrower in August when the Earth is at aphelion.

Fig. 3. Solar Array Output.

Although the batteries can be used to supplement the solar cell power and support operations over a wider range of Beta, this is minimized to prolong battery life and conserve their capacity for the more critical eclipse seasons. An FOD limits the number of times IUE may be used in a power-negative or power-neutral situation in any one year and the duration of any one such session. There are also constraints on the magnitude of current drain and other related operational parameters.

4.4. Radiation

The principal source of radiation affecting IUE is the Earth's out trapped electron belt. Compared to a circular geosynchronous orbit which would lie on the upper side of this belt, IUE's elliptical orbit dips into a region of higher electron flux at perigee. Towards apogee, however, there is a large portion of the orbit where the radiation is substantially less. Based on calculations of the expected radiation, the sensitive elements of the IUE systems were provided with shielding to the maximum extent possible within weight and design constraints (see Boggess and Wilson 1987). At a late stage, because of concern about radiation levels, a particle detector was added to IUE. In April 1991, this detector began to fail, and the staff at GSFC developed an alternate method in which the electron flux levels measured by the weather satellite GOES 8 are analyzed to determine the approximate radiation level around IUE. This voltage is monitored on the ground and at the predefined safety limit of 3.6 V the operating cameras are switched to the standby mode. This limit is only occasionally reached, and at this radiation intensity the background induced in the camera precludes useful exposures, even short ones. The orbit is such that the radiation principally affects the US2 shift which is consequently mainly scheduled for programs with short exposures and for maintenance. In addition to camera background, the radiation was expected to adversely effect some of the electronics and possibly the magnesium fluoride camera faceplates by the end of the three year design life. Recently, accumulated radiation damage to the DMU has restricted operations to temperatures below 26.2°C. This limit is usually avoided by insuring that the OBC remains below its own temperature limits (see below.)

4.5. Temperature

It is essential to keep the temperature of the various IUE components and subsystems controlled within certain limits. To monitor these temperatures, there are thermistors located in critical areas; their output is delivered to the telemetry via a subcommutator. In the IUEOCC, the thermistor outputs are converted to temperatures for display on the monitors. Preset limits are built into the computer system, and these cause the temperature displays to flash or blink when the limit is reached. The limits are set so that the operating analysts are warned that the parameter is outside its normal range. Usually no immediate action is required at a blink limit; however, if the `redline' limit, an absolute value set by the design engineers, is exceeded then corrective action must be taken. The OBC and DMU are cases in point. Since their temperatures are affected by the sun angle, Beta, and also by the Earth-Sun distance, there is a thermal constraint on Beta that is most restricting at perihelion. Presently there is no limit on science operations if the OBC is below 54.6°C or if the DMU is below 26.2°C; but if the temperature stabilizes at one of these values then IUE must be maneuvered outside the range 40° < Beta < 105° within one hour in order to cool off. There are also special circumstances, e.g. prior to performing an orbit adjustment, when it is expeditious to cool the OBC before taking a particular action, even though it may be below the blink limit. There are some 90 telemetered temperature points that are subject to blink or redline constraints covering such components as batteries, gyros, electronics, propulsion systems, solar arrays, etc.

4.6. Momentum Wheel Speed

An FOD covers the control of the momentum wheels to provide smooth spacecraft control and to prevent excessive wear of the bearings. At the start of the mission the wheel speeds were normally kept between 250 and 1000 rpm in either direction. The wheel speeds are permitted to run through zero or to saturate during maneuvers. When the combination of gyros 1, 3, and 5 was no longer available for emergency attitude recovery, the momentum stored in the wheels had to be reduced so that they could always bring IUE to a safe hold attitude using the analog Sunbath mode. At that time the wheel speed for normal operations was changed to 200 to 500 rpm for roll and yaw and 200 to 1000 rpm for pitch. To date there have been no mechanical problems with the momentum wheels, and even if one of the orthogonally oriented ones should fail there is a spare that could contribute to any of the three axes.

5. Problem Areas

The problems that have occurred with IUE can generally be divided into two categories, those arising in spacecraft systems and those in ground facilities. With regard to the latter, most are related to an aging hardware system and operational software shortcomings which continue to be found throughout the lifetime of the program. However, the ground system problems, hardware or software, can be and are dealt with, although often at the expense of considerable effort. We will not dwell here on these ground system problems, for they are for the most part those common to any complex computer system. Although retrieval and repair of failed spacecraft has been demonstrated, this is very costly and can at present only be done for a low Earth orbit case. Until the development of robot repair missions, any anomaly occurring aboard the IUE spacecraft must be dealt with by changes to the commands transmitted to the satellite or by adopting workaround procedures or by switching to redundant subsystems.

In planning the operations of IUE a very high priority has been given to the safe preservation of the satellite and conservation of resources within the constraints of providing a scientifically effective and productive mission. Even with this approach anomalies can and have occasionally occurred in several systems, but those in three systems, the gyros, the OBC, and recently the FES, have caused the most concern and are described below. Other systems have degraded in an expected (non-anomalous) fashion, e.g. the solar cells which result in Beta constraints as described in Section 4.3. Problems have also occurred in the S/I. Those occurring in the camera system have been potentially the most serious and these are also described below.

5.1. Gyros

The most troublesome operational system (from the point of near catastrophe) has been the gyros, which are essential to the attitude control of IUE. Thanks both to careful and original design concepts and also to subsequent foresight and ingenuity by a number of people associated with the program, it has been possible to maintain the performance of the ACS. As a result, satisfactory scientific data collection has continued for over 16 years from launch to the time of writing. The original planning foresight was to build a six gyro package (see Figure 4) that was designed to maintain three-axis control as long as any three gyros were operational. This mode was used for 7.5 years during which three of the gyros failed.

Fig. 4. Inertial Reference Assembly.

The first three gyro failures occurred as follows. During the third eclipse season, in the Spring of 1979, three of the then six operating gyros (Gyros 2, 4 and 6) were turned off to conserve power. At the end of the eclipse season Gyro 6 failed to restart, although a number of attempts were made. (Hope has not been permanently abandoned for Gyro 6, as will be seen below.) In the middle of 1981, maneuver accuracy decreased and telemetry analysis indicated that Gyro 1 was suspect. It was taken off-line and a further analysis finally led to the conclusion that the feedback loop was open and the gyro was not recoverable. Gyro 1 was designated a permanent loss in March 1982. In July of the same year IUE began to slowly drift. Gyro 2 telemetry showed a rapid increase in current indicating that the gyro had stalled. At this point Gyro 2 was written off and the control software changed so that the spacecraft would be operating with the remaining Gyros 3, 4, and 5, at which point IUE had no spare gyros left. Seemingly, one more failure would mean the end of scientific observations. The IUE mission managers had anticipated this possibility even before the loss of the third gyro and had asked that the attitude control experts should prepare contingency plans.

They concluded that a method of attitude control could be worked out that used two active gyros and the Fine Sun Sensor (FSS). A program was planned and teams formed to develop, build and test such a system. The testing was done on simulators, as tests on the spacecraft were considered an unacceptable risk. By Spring 1983 the two-gyro/FSS control system had been carried as far as it could go, short of spacecraft usage. As it turned out, for three years (from July 1982 until August 1985) the satellite operated satisfactorily on the three remaining gyros. Then on 17 August 1985 the critical situation was eventually reached: Gyro 3 failed. The spacecraft's gyro body angles began to drift in a situation when they should have remained fixed and the Gyro 3 current fell from a normal operating level of 65 mA to 2 mA. The duty IUEOCC Operations Director immediately recognized the situation and took the action necessary to place the satellite in the safe, Sunbath, mode. The Sunbath mode uses analog information from the sun sensors to orient the satellite to Beta = 67° which gives the maximum output from the solar array. However the satellite slowly rotates about the yaw axis (z-axis) thus eventually requiring an attitude recovery exercise. After due consideration, it was decided to try to restart Gyro 3, but to no avail. A conference was called of all experts who could contribute to the situation, and it was decided to try to restart Gyro 6, but not so vigorously as to cause further damage in this already critical situation. If this failed, then the trusted but untried two-gyro/FSS system would be brought into play. Gyro 6 did not restart and the new system was now the only hope. It worked! Not smoothly at first, but with careful nurturing, it evolved in a few more weeks into a system that enabled IUE to gather scientific data essentially as well as in the old days of the three-gyro mode. At the time of writing it continues to do so, always with new improvements being evolved. This was a very great and ingenious achievement by the staff involved.

Even this two-gyro system is not seen to be the terminal control system, for considerable progress has been made in the development of a promising one-gyro/FSS system, and it is possible that, in the event of another gyro failure a workable system could be operational within a few months. The one-gyro/FSS system, unfortunately, may not be useable with the recent presence of the FES streak (see Section 5.3). Finally, even a no gyro operation may be possible using the FES and FSS and making only small slews from star to star but science operations would be greatly restricted.

5.2. On Board Computer (OBC)

The OBC is the other spacecraft component identified above as prone to operational anomalies. Indeed, prelaunch, the OBC was the cause of major concern due to malfunctions when running `hot'. If the ACS can be considered the nerve and muscle of IUE, then the OBC is certainly its brain, for its function is to tell the ACS and other systems what to do and when to do it. It does this through a number of installed software routines called `workers' which are in turn controlled by the computer executive system program. These workers are algorithms designed to perform specific spacecraft tasks. When there is a problem involving the OBC, it usually seems to involve the malfunctioning of the executive system hardware, with its subsequent effect on the performance of at least one of the workers. Over the lifetime of the satellite there have been numerous OBC malfunctions. While not always understood (mainly due to limited monitoring telemetry), most have not had any major impact on operations; i.e. the effect of the malfunction was easily and quickly corrected, usually by the simple retransmission of a command. However, there have been cases when attitude control was lost and recovery required a great deal of effort on the part of the RAs and the IUEOCC personnel. During the first three years of operation, 1978-80, the OBC was prone to crashes that caused loss of attitude. The OBC software analysts, OBC hardware engineers and operations personnel identified the conditions under which these crashes occurred. The software analysts then inserted code to detect the failures when they occurred, and restart the OBC control. As various failure modes occurred with time, the OBC code was modified until OBC crashes were no longer a significant operational problem. This worked so well that continuing failures, `hits', would have been undetected so a counter was inserted to record them. Many times there were several hundred `hits' per day from which recovery was automatically made without impact. The `hits' have decreased to only a few per day in recent years.

Another class of anomaly in the OBC was concerned with camera control. A VILSPA study of this phenomenon in June 1980 suggested, but not conclusively, that these problems might be associated with passage of IUE through transitional regions of the radiation belts. These OBC-related camera anomalies still occur on occasion, but are usually caught quickly enough to minimize the effect on the science.

One type of anomaly that has occurred twice, each time causing major concern, is the failure of the OBC to carry through a successful orbital adjustment (DELTA-V) to keep IUE on station. The first time that this occurred was on 12 January 1984. Prior to this DELTA-V there had been eight without incident. The magnitude of the DELTA-V is controlled by the duration of the firing of IUE's high thrust jets. The durations are calculated and the values are inserted into the Worker 19 command sequence which controls the operation. In January 1984 it was planned to fire the appropriate jets for 8.2 seconds but the program aborted after 1.64 seconds, leaving IUE in a slow spin. It took over four hours to restabilize the spacecraft and several hours more to determine its attitude. After analyzing the orbital data a new DELTA-V was planned and successfully carried out on 14 February 1984 without doing anything different except cooling the jets by orienting them away from the Sun prior to firing. The next DELTA-V in November 1984 also proceeded without incident but July 1985 brought a repeat of the fault of January 1984. After collective consultation with the experts it was concluded that differences between successful attempts and failure lay in the yaw phase data. The operational plan was modified so that the next try would emulate the successful DELTA-Vs, which had a negative yaw angle start. On 9 August the exercise was repeated and was successful. It is not known for certain whether the problem had been correctly identified since only eight days later the failure of the fourth gyro occurred and Worker 19 had to be extensively modified for use in the two-gyro/FSS mode. The two DELTA-Vs carried out since have both been successful.

5.3 The FES Streak

As stated earlier (see Section 3.3.1), the FES can, in theory, identify stars as faint as V = 14 mag. There have been some problems in recent years which have come to significantly affect the FES's abilities. On 5 February 1991, VILSPA reported the presence of a uniform scattered light background in the field of view, comparable to what one might see from V = 12 mag stars filling the field. This occurred during the Winter shadow season which, among other things, subjected IUE to greater temperature changes than it experiences at other times of the year, and may have caused this anomaly to appear. The speculation was that some of the thermal insulation had peeled off of the telescope tube and was now reflecting sunlight into the tube.

The scattered light intensity correlated very well with Beta, in the sense that higher Beta yielded a higher background, and was virtually non-existent at lower Beta. There were also fluctuations in intensity as time went on for any given Beta which were not predictable. Although initially alarming, the scattered light's presence did not have a substantial effect on IUE's observing capabilities. Faint targets were acquired as blind offsets, long wavelength high dispersion and short wavelength high and low dispersion spectra were not contaminated, and long wavelength low dispersion spectra were contaminated only for exposures longer than several hours.

Then on 14 September 1992 the scattered light anomaly became even more anomalous. At the end of a maneuver to a target near the Orion Nebula, the staff noticed that there was a bright streak of light in the field of view, comparable to a V = 5 mag star. They were not initially alarmed because they believed this feature was simply the Earth's limb, which they knew was nearby. However, this feature did not go away as they expected it to, and the staff became very concerned that a potentially mission-threatening event had occurred. The feature disappeared without any trace a few hours later while it was being investigated, leaving the staff to wonder if it would be seen again. A month or so later, it did return for a few days, then it was absent, but over time it became a regular feature in the field of view. As it started to make its presence felt, the streak (as it is known and loathed) became more of a problem, filling up to 80% of the field of view and at times saturating the FES detector in parts of that field. The staff concluded that this new problem, like the previous scattered light trouble, is being caused by some of the thermal insulation scattering sunlight, and sometimes Earth light, into the telescope tube. This insulation, while causing the streak, is not physically blocking the tube, since stars can still be seen throughout the field of view; the streak simply adds to the star's intrinsic brightness.

Remarkably enough, science efficiency and data quality have not been substantially affected since the streak's appearance. The staffs at both VILSPA and GSFC quickly developed workarounds for acquiring targets. The same variation with Beta angle that was seen with the scattered light is present with the streak, although there is no Beta at which it disappears altogether. Also, the streak has changed appreciably in the past year, and may be getting less intense as time goes on. As with the previous background, only long wavelength low dispersion spectra show any contamination, but that contamination can now appear in less than one hour. The staffs at both ground stations, as well as several independent observers, are working to find ways of reducing or eliminating this contamination from target spectra. The fact that spectra of the streak are similar to spectra of solar-type stars supports the conclusion that the illumination sources are the Sun and Earth.

The greatest impact has yet to be realized. The one-gyro/FSS system that was previously developed relies criticaly on the FES's ability to identify stars brighter than about V = 9 mag to maintain IUE's stability while on target. The streak intensity at Betas > 75° can wash out all but the brightest stars, which frequently leaves nothing visible in the field of view. This situation is not a problem with the two-gyro/FSS system since IUE can function quite well without the FES in the attitude control loop for the better part of an hour. After that, a short maneuver (on the order of a few arc minutes) is needed to find a star to verify IUE's pointing. But if there is another gyro failure, it is quite likely that, at best, IUE will be confined to observing targets at low Betas, and then only when bright enough stars are in the field of view.

5.4. Fine Sun Sensor (FSS)

Since the FSS is now a key part of the ACS, used to provide both roll and pitch information, its anomalies have assumed greater importance than before. It will play an even greater role in the attitude control if the one-gyro/FSS has to be installed. The FSS contains dual systems, each of which consists of an electronics package and dual detector heads. The two systems each cover an angular range of ±32° in pitch and roll centered on Beta = 45° and Beta = 105° respectively. There is an anomaly in the low-Beta FSS that prohibits operations below Beta = 28° since the two-gyro/FSS control system was put into operation.

5.5. Cameras

Four problems have occurred with the cameras. The first two, microphonic noise and scan control logic failures, have been largely overcome by changed operating procedures. The third has been the almost certain loss of use of the back-up or `redundant' camera in the short wavelength spectrograph (SWR). Fourthly, a high voltage discharge developed in the redundant long wavelength camera (LWR) and it can now only be operated at reduced gain.

The IUE TV camera tubes are very sensitive to mechanical vibrations particularly at frequencies in the range 500 Hz-10 kHz. This sensitivity arises because the support structure of the SEC target is a 2 cm diameter film of aluminum oxide 50 nm thick, which has high-Q resonances in this frequency range. The target, connected to a very sensitive amplifier, acts as a condenser microphone. During the commissioning of the S/I, severe microphonics frequently occurred. This was tracked down to the panoramic attitude sensor (PAS) which was used to sense the Earth limb in order to determine IUE's attitude during the initial attitude acquisition process. After use, the PAS had been left switched on with its scanning prism rotating but, on discovery, was switched off.

Occasionally important data were lost due to a microphonic `ping' lasting 10 seconds that affected the LWR images by producing a band of interference across the image. It was eventually discovered that this `ping' was induced by the warm up of the heater in the readout gun of the LWR tube. By increasing the delay between turning up the heater voltage and the commencement of the readout scan, it was possible to insure the `ping' occurred before the scan started.

The second problem occurred in the setting up of the digital logic circuits that perform the readout scan of the LWP camera. When the circuits have remained unused for some hours, e.g. during a long exposure, the serially loaded set-up coördinates fail to pass a specific bit in the line scan register. When the scan is initiated the register then counts correctly but from the wrong starting point so that only part of the SEC target is read out. The solution to this, which took quite some time to develop into a reliable form, was to include in the operating procedure the initiation of a dummy scan to insure the logic was unlatched prior to commencing the readout scan.

The third problem has been the intermittent operation of the SWR camera tube arising from a loss of the G1 on voltage, which controls the electron readout beam current. The SWR camera was selected at the outset to be set up and calibrated in orbit for routine use in the short wavelength spectrograph. In the middle of this commissioning period the intermittent operation first occurred. At that time the decision was made to use the SWP camera routinely and this has operated flawlessly to date. At intervals, attempts were made to operate the SWR camera and it was soon observed that successful operation was much more likely when the camera electronics module was cold. As time has gone by successful reads have become less frequent even at low temperatures, and it seems unlikely that the SWR camera would be of any use in the event of the failure of the SWP. One possible cause of the failure is the loss of the clock pulse input to the G1 modulator. Such problems had occurred on the ground due to a poorly mating connector.

The fourth major problem has been the high voltage discharge or `flare' that has developed in the LWR camera. A proximity focussed intensifier, whose output is coupled by fiber-optic windows to the TV tube, acts as a UV-to-visible wavelength converter. The high electric field (3.8 kV mm^{-1}) is near the maximum that the materials used for the photocathode and the anode can stand without a discharge developing. Any enhancement of the electric field caused, for instance, by a sharp point on the photocathode or contamination by a low workfunction electron emitter can result in an electron (or ion) discharge that gives rise to a point of light in the output image of the converter. The flare intensity increases rapidly as the voltage across the converter is raised, the image is enlarged due to scattering and halation, and further flares with a higher threshold voltage may appear. The phenomenon caused very considerable problems during the development of the IUE cameras. It was only after considerable labor by the project, and the eventually-successful converter manufacturer, ITT, that acceptable converters were made. The development was very successful. The high photocathode efficiency and very low background count rate (in the absence of radiation), which were better than specification, directly contributed to the performance of IUE. A difficult compromise had to be made between tube gain, safety margin from flares and reasonable production yields. The converters were formally rated at a maximum of 6 kV and some testing for flares and background was carried out at that voltage, but for all other testing and operations a voltage of 5 kV was selected.

In 1983 a weak flare was discovered in long exposures on the LWR camera. The center of the discharge was just outside the field of view of the TV camera but well within the working area of the converter, so only a crescent of light was picked up by the TV tube. Subsequently the flare steadily increased in intensity and therefore affected shorter exposures. The size of the light patch has also greatly increased. Fortunately the LWP had been calibrated and was made available to observers since it offered improved sensitivity in some parts of the spectrum. In October 1983 the decision was made to switch to the LWP for all normal observations. At first, use of the LWR was still permitted at 5 kV to complete series of observations of variable objects, but from April 1985 operation has been restricted to 4.5 kV which is at present below the flare threshold. This has reduced the gain by 27%.

On one occasion in 1976, during laboratory acceptance tests on the LWR converter before coupling to its TV tube, an extremely weak pinpoint of light was detected when making a 2 hour exposure at 6 kV but this did not recur on subsequent tests. The position of that flare is exactly coincident with the deduced center of the flare now seen through the TV camera. It is assumed that some aging process has lowered the flare threshold voltage. The extreme difficulty in producing completely flare-free converters forced the project to take the risk of including this one in the flight equipment. With hindsight this gamble has been well justified by five years of trouble-free operation by the LWR. Obviously such aging effects as have been seen in the LWR now raise the question of whether flares may in time appear in other cameras. These were not tested above 6 KV so there is no information as to whether they may have had incipient flare points which could appear at higher voltages.

6. Operational Performance

Despite the problems described above, IUE is still operating at high efficiency nearly 16 years into a mission which was originally designed for three years with consumables sized for five years. The ability to reconfigure IUE and achieve the mission objectives in quite different ways has been one of the important factors contributing to its extended life.

The scientific efficiency of IUE was not high in the first month or two after launch. The operational procedures and the ground computer software needed some debugging and extensive tuning to reduce unproductive overhead time when IUE was essentially waiting for the next command to be uplinked. As the operations staff gained confidence in the use of the improving software IUE soon achieved an average efficiency (defined as the fraction of time spent collecting astronomical photons) of about 60%. It was expected that the increased constraints on pointing in recent years would tend to reduce efficiency but this has been compensated by increased attention to efficient scheduling. At some point in the future it may be necessary to employ integrated operations so as to maintain efficiency by forming an optimum observing sequence from all the target lists of several GOs in one time interval.

At the time of writing, IUE is still in very good shape, with its scientific performance essentially unimpaired since launch over 16 years ago in January 1978. The targets it had observed by March 1986 included:

- 90 Solar System objects (planets, moons, asteroids, and comets).
- 5330 Hot stars (O, B, A, S, WD, and WR).
- 2060 Cool stars (F, G, K, and M).
- 1340 Variable stars (novae, Cephids, T Tauri, and binaries).
- 910 Nebulae (planetary, HII, and SNR).
- 1200 Extragalactic objects (galaxies, Seyferts, and QSOs).

These observations have resulted in the production of almost 95,000 spectral images, collected on behalf of more than 1200 astronomers, and have resulted in over 2100 papers being published in refereed journals.

The IUE archive has assumed increasing importance (see Giaretta *et al.* 1987); any image can be obtained after expiration of the 6 months exclusive data rights held by the original observer. Currently over 70,000 spectra per year are requested and the rate of requests now exceeds the rate of acquiring new spectra.

7. Abbreviations

It is convenient and customary among the IUE community to use abbreviations when referring to the various complex systems. We have restricted their use here to the more common ones. A list follows of all those used in this paper both those specific to IUE and those in more general use.

- ACS Attitude Control System

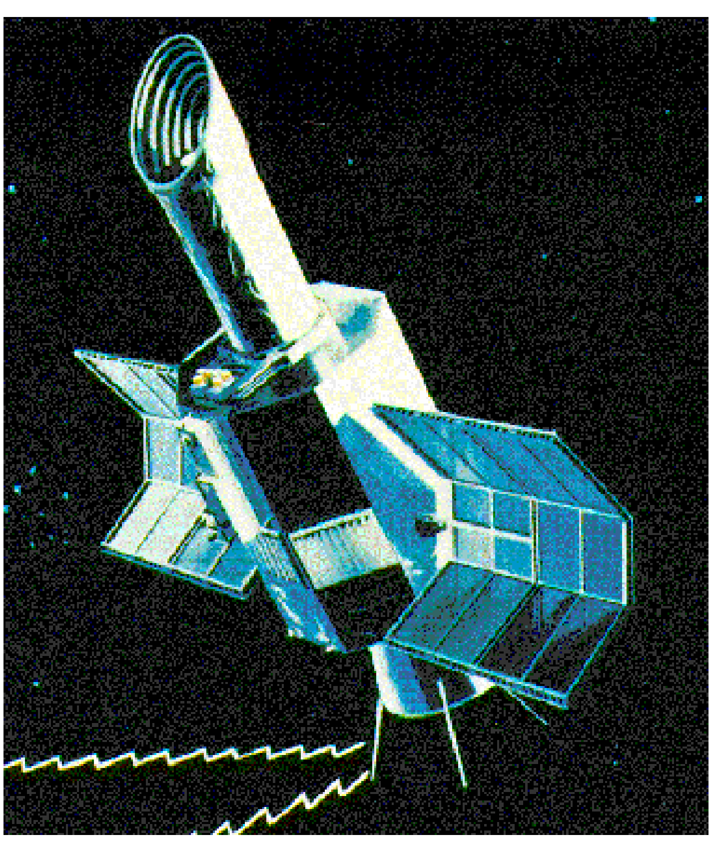
The IUE Spacecraft



Mass: 644 kg at launch, 462 kg in orbit

Dimensions: 4.2 m by 1.45 m by 1.45 m

Power: 2 solar panels, which provide operating power to the spacecraft, and 2 batteries, which provide power during biannual Earth shadow seasons

Slewing: 3 reaction wheels (1 backup, never used)

Attitude sensors: 2 gyros (out of original 6), 1 Fine Sun Sensor (1 backup)

Computers: 1 8k on-board computer (1 backup, never used)

Orbit: synchronous, with semi-major axis 42167 km, inclination 34.7 deg, and eccentricity 0.132 (as of mid-1994)

Telemetry: uplink at 148.98 MHz (VHF) at 0.8 kbits/sec; S-band downlink at 2249.80 MHz at rates from 1.25 to 20 kbits/sec (standard), or VHF downlink at 136.86 MHz at rates from 1.25 to 5 kbits/sec

Ground stations: NASA IUE Observatory at Goddard Space Flight Center, Greenbelt, MD, USA (via Wallops Island Flight Facility, VA, USA), and ESA IUE Observatory at Villefranca del Castillo, Madrid, Spain

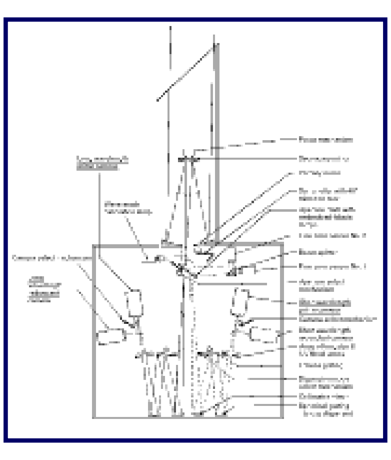
Command method: Real-time commanding by on-station personnel under advice from peer-selected guest observers; no coordination with TDRSS or other ground communication systems needed

More information?

Please see the article "Operation of a Multi-Year, Multi-Agency Project" describing the IUE mission (Falker, J., Gordon, F., Sanford, M.C.W., 1987, *Exploring the Universe with the IUE Satellite* , Reidel (and appears here with permission of Kluwer Academic Publishers): Dordrecht, ed. Y. Kondo, pg. 21).

Also, the IUE Observing Guide gives a description of the spacecraft, instrument, observing constraints, and so forth. (Important updates and details on the instrumental status were added by J. Caplinger in 1994.)

Scientific Instrument



The IUE scientific instrument consists of a telescope, acquisition camera, two ultraviolet spectrographs, and four cameras.

Telescope: The telescope is a 45-cm aperture, f/15 telescope of Ritchey-Chretien design. The primary mirror is made of beryllium. Thermal heaters mounted on the back of the mirror and on the camera deck are used for focus control.

Acquisition camera: The Fine Error Sensor (FES) is an image dissector device sensitive to a broad range of visual wavelengths. It has a 16 arcmin field of view and effective image resolution of about 8 arcsec. The device is used in camera mode to obtain a visual star field image for target identification and acquisition. It is then used in tracking mode for offset guiding, providing a pointing stability of about 1/2 arcsec.

Apertures: Each spectrograph may be used with either of two apertures. The large aperture is a slot (approximately 10 by 20 arcsec) and the small aperture is a circle about 3 arcsec in diameter. The apertures are known as LWLA (long-wavelength large aperture), LWSA (long-wavelength small aperture), SWLA (short-wavelength large aperture), and SWSA (short-wavelength small aperture). The image quality of the IUE telescope's optics yields a roughly 3 arcsec image, so observations using the small aperture result in some light loss. The large apertures are used most frequently since they give photometric reliability with little or no loss of resolution.

Spectrographs: The long-wavelength spectrograph operates in a wavelength range of 1850 to 3300 Å. The short-wavelength spectrograph operates in a wavelength range of 1150 to 2000 Å.

Dispersion modes: Each spectrograph has two dispersion modes. High resolution employs an echelle grating and cross-disperser, giving roughly 0.2 Å resolution). Low resolution employs the cross-disperser grating alone, and yields approximately 6 Å resolution.

Cameras: There are four cameras, two for each spectrograph. One is designated prime and the other backup. In the long-wavelength range, both the prime (LWP) and redundant (LWR) cameras were used during the mission. With the short-wavelength spectrograph, only the prime camera (SWP) was fully functional. The redundant camera (SWR) was used to obtain a handful of images early in the mission. Each camera consists of an SEC Vidicon with and ultraviolet converter. Each exposure is obtained by integrating over the requested exposure time, then performing a destructive readout of the camera target. The signal is digitized and transmitted to the ground via the spacecraft telemetry stream.

Data format: Each IUE image consists of a 768 by 768 pixel array of 8-bit values (0 to 255). The raw data are archived with a header recording Telescope Operator comments, automatic activity log, and spacecraft engineering data.

IUE OBSERVING GUIDE

Jeffrey S. Newmark, Albert V. Holm, Catherine L. Imhoff, Nancy A. Oliverson, Ronald E. Pitts and George Sonneborn

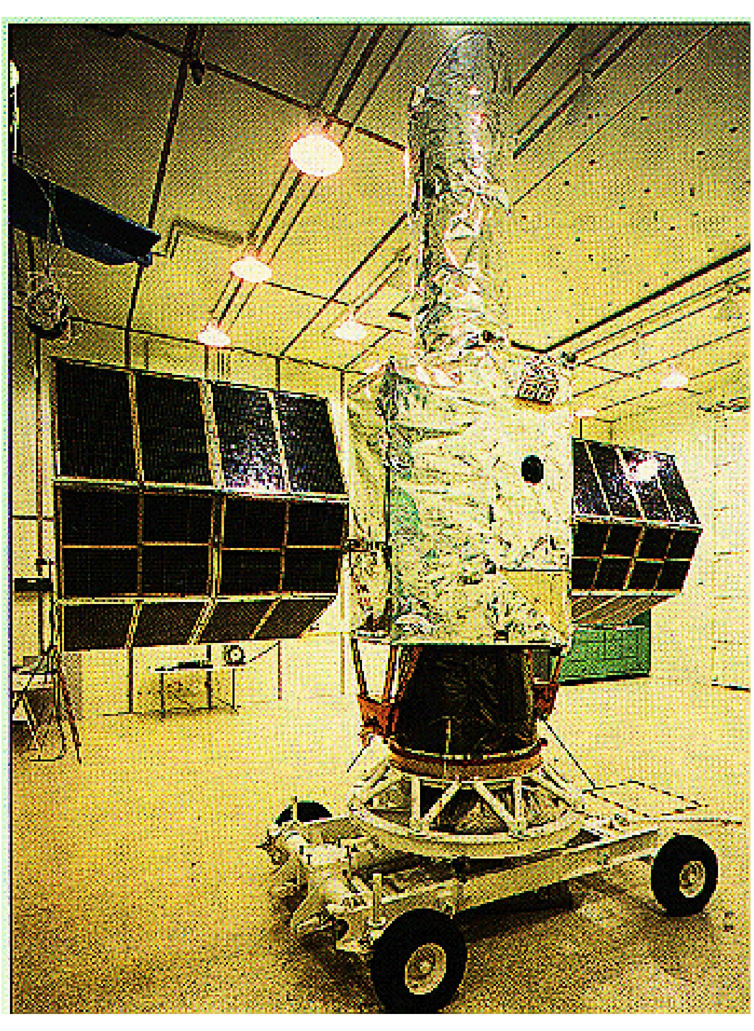
The Early History of IUE



IUE in the Clean Room Before Launch

The beginning of IUE goes back to the late 1960's and the success of the early astronomical satellites such as OAO-2 and Copernicus (OAO-3) in the US and TD-1 in Europe. Various studies were being pursued at NASA and within the European Space Research Organization (ESRO, the predecessor of ESA) for new astronomy satellites. One such study, for an Ultraviolet Astronomical Satellite (UVAS), was proposed by a team from the UK. This became the basis for a joint project among NASA, ESRO, and the UK's Science Research Council (SRC).

The approval process was especially challenging, since it involved three different agencies. But approval for the International Ultraviolet Explorer was won in 1971. Under the interagency agreement, NASA was reponsible for the overall system design, design and construction of the telescope, spectrograph, and spacecraft, the launch, and the US spacecraft control station at Goddard Space Flight Center (GSFC). The UK was responsible for the design and construction of the cameras and contributed to the optical design and the sunshade. ESA provided the solar arrays and the European spacecraft control station near Madrid, Spain.

Several unique design elements were part of the planned IUE mission.

First, the spacecraft was to be placed into geosynchronous orbit. This would allow it to be controlled in real time and thus be operated much like a ground-based observatory. Weight was therefore a major consideration. One compromise was to place the spacecraft into an eccentric orbit. In this orbit, the spacecraft dipped into the Van Allen belts at perigee. This became the "US2" high radiation shift, during which observers took shorter exposures because of the radiation background affecting the cameras.

Second, the goal of a long scientific mission was incorporated into the project design. The scientists pushed hard for a five-year mission. But the engineers would agree only to a three-year design lifetime, with a five-year "goal" as a compromise. Ironically IUE lasted *much* longer than five years!

Finally, control of the satellite would be passed between two control stations on two different continents. This concept caused some concern, since a clear chain of command is required for safe, successful spacecraft operations. Various steps were taken to insure well-coordinated operations. A standard protocol was used for "handover" of command between the two stations. The Goddard control center stayed online during VILSPA shifts to monitor and backup the European operations. Both stations used essentially identical command computers, software, and Flight Operations Directives.

Concerns about the radiation enviroment resulted in the last-minute installation of a radiation monitor. As it turned out, the radiation environment was not as bad as feared, but the radiation monitor was very useful in helping the observers better estimate exposure times during the high radiation shift.

IUE was launched on January 26, 1978, on a Delta rocket from Cape Canaveral, Florida. It was placed initially in an eccentric transfer orbit, then the apogee boost motor was used to circularize the orbit. After this IUE was so close to its nominal station (i.e. longitude) that it was not neccesary to use the jets move the spacecraft orbit. Initial check-out of the hardware went smoothly. The first spectrum, of the calibration star Eta Ursae Majoris, was obtained on the third day.

The spacecraft was then operated for 60 days under a Commissioning Period. Various high priority calibration and science observations were performed. For each spectrograph, there were prime and redundant cameras. It was quickly learned that the Short-Wavelength Redundant (SWR) camera was not functioning properly, and it was not used after the Commissioning Period. The SWP camera experienced significant microphonic noise, a major concern, until the source of the noise was found (the Panoramic Attitude Sensor, used for attitude determination after launch) and turned off. The LWP camera, in some ways better than the LWR, experienced sporadic scan errors, so the LWR was chosen as the default long-wavelength camera.

Routine operations began on April 1, 1978... and continued until October 30, 1996, an amazing 18 years and 9 months!

More information?

Please see "The History of IUE" (Boggess, A., Wilson, R., Barker, P. J., and Meredith, L. M. 1987, in *Scientific Accomplishments of the IUE*, Reidel: Dordrecht, ed. Y. Kondo, pg. 3). Most of the information above is condensed from this excellent article.

In addition, please see the series of articles written about IUE published in *Nature* , beginning with Boggess, A., *et al.* , 1978, *Nature* , **275** , 372. The first paper describes IUE, while the others describe the results of the Commissioning Period observations of various types of astronomical objects.

Phase-Resolved Spectrophotometry of the ZZ Ceti Variable G 29-38

FBDCB - C. Stuart Bowyer (Berkeley)
High Dispersion Observation of HZ 43

FBDCW - Chi-Chao Wu (CSC)
UV Observations of the Probable Stellar Remnant of Supernova AD1006

FBDJL - J. D. Landstreet (Western Ontario)
UV Spectrophotometry of the Magnetic White Dwarf GD 229

FBDRG - Richard F. Green (U Arizona)
Very Hot Pre-Degenerate & Mixed Atmosphere Subdwarfs from the Palomar-Green Survey

FBDTA - Thomas B. Ake (CSC)
UV Observations of the Unseen Companion to Zeta Cancri C

FBEAH - Albert V. Holm (CSC)
Phase-Resolved Spectrophotometry of the ZZ Ceti Variable G29-38

FBPBB - Bernard W. Bopp (U Toledo)
Pulsationally Induced Mass-Dumping in F + B Binaries

FC015 - S. Rucinski (Munchen)
UV Variability of FK Comae

FC016 - K. Fredga (Stockholm)
Stellar Activity Cycle in Beta Hydri

FC017 - Pallavicini (Firenze)
Active Chromospheres and Coronae of Late-Type Stars

FC027 - P. L. Bernacca (Osservatorio Astrofisico DI Asiago)
Population II B-Type Stars with Weak Helium Lines

FC029 - M. Hack (Trieste)
The Atmospheric Eclipsing Binary Epsilon Aurigae

FC030 - M. Hack (Trieste)
The Symbiotic Star CH Cygni

FC044 - O. K. Moe (Oslo)
UV Observations of Inhomogeneous Red Dwarfs Atmospheres

FC046 - D. Koester (Kiel)
UV Spectroscopy of White Dwarfs

FC053 - O. Engvold (Oslo)
UV FEII Flourescence in Cool Giant and Supergiant Stars

FC055 - C. Jordan (Oxford)
Coronae and Chromospheres of Cool Giants and Supergiants Dependence on Spectral Type

FC061 - C. Jordan (Oxford)
A Study of Two, Young, Solar-Type Stars

FC062 - C. Jordan (Oxford)
High Dispersion Observations of Alpha Boo

FC068 - S. Rucinski (Munchen)
High Resolution Spectra of Two FK Comae-Type Stars

FC097 - A. J. Willis (London)
Physical Properties of the Accretion Disk in RZ Oph

FC109 - D. Reimers (Hamburg)
Winds and Coronae in Red Giants

FC110 - D. Reimers (Hamburg)
Mass Loss of Red Giants with Hot Companions

FC123 - G. E. Bromage (Ral)
Study of M-Dwarf Flares

FC124 - Oxford (Oxford)
A High Resolution Study of the Jet of R Aquarii

FC138 - Michael V. Penston (RGO)
Short Wavelength Line Profiles in T TSuri stars

FC142 - M. Fernandez-Figueroe (Madrid)
Chromospheric and Coronal Activity in Regular-Period RS CVN-Like Stars

FC150 - C. Jordan (Oxford)
The UV Variability and Rotational Modulation of T Tauri Stars

FC187 - Osmi Vilhu (Copenhagen)
Simultaneous Exosat and IUE Observations of VW Cep and 44 Boo

FC198 - Mewe (Utrecht)
Chromospheric and Coronal Activity of K-Type Giant Stars in Binaries

FC199 - Reza (Brazil)
Simultaneous Ground-Base and UV Observations of the Star V 4046 SGR

FC201 - L. Bianchi (Torino)
IUE Observations of FK Comae Stars with Coordinated Ground-Base Photometry

FC203 - L. Bianchi (Torino)
Observations of Orion Nebulary Variables Emitting Soft X-Rays

FC210 - G. F. Gahm (Stockholm)
Modelling of the T Tauri Star RU Lupi

FC215 - F. Giovannelli (Frascati)
UV, Optical and IR Observations of T Tauri Type Stars

FC220 - S. Catalano (Catania)
UV Observations of the Secondary Component of Algol-Type Binaries

FC221 - S. Catalano (Catania)
MG II Emission of MS Stars in Open Clusters

FC225 - O. Engvold (Oslo)
Determination of Absolute Velocities for Emission Lines in Late-Type Stars

FC231 - W. Eichendorf (Munchen)
Masses of Cepheids

FC232 - W. Eichendorf (Munchen)
Classical Cepheids and Their Blue Companions

FC241 - F. Querci (Toulouse)
High Resolution Ultraviolet Spectra of the Carbon Star Tw Hor

FC249 - M. Rodono (Catania)

IUE Observations of Surface Structure of Eclipsing and Non-Eclipsing RS CVN Systems

FC251 - B. Gustafsson (Uppsala)
High Dispersion Study of Luminous Cool Stars

FC254 - C. J. Butler (Arnagh)
Time Scsales of Dwarf Flares

FC265 - M. Querci (Toulouse)
Carbon Stars Sequence: R to N Stars

FC268 - C. Cacciari (Vilspa)
IUE Observations of Pop II Standaed Stars

FD175 - F. D'Antona (Francati)
Hot White Dwarfs

FDJJL - Jeffrey L. Linsky (Colorado - JILA)
First Observations of the Pleiades Transition Region Line Emission

FDLTS - Theodore Simon (Hawaii)
Chromospheric Activity in the Early F Stars

FE002 - F. Fusi-Pecci (Bologna)
The Integrated Spectra of Globular Clusters in M31 and the Fornax Dwarf Galaxy

Spectrometry of Selected Early-Type Stars, Magellanic Wolf-Rayet Stars and Galactic Nucleii

MSJLW - Lee Anne Willson (Iowa)
A Stars in the Pleiades

MSJRP - Ronald E. Pitts (CSC)
Fluxes, Temperatures, and Radii of Stars Defining the Zams

MSLHJ - Hollis R. Johnson (Indiana)
Ultraviolet Spectra and Chromospheres of S and Ms Stars

MT384 - M. Tarenghi (ESA)
UV Observations of Double Active Galaxies

MU009 - M. H. Ulrich (France)
Observations of Nuclei of Two Seyfert Galaxies and A Qso

MU120 - M. H. Ulrich (ESA)
NGC 4151

MU373 - M. H. Ulrich (ESA)
Monitoring of the Continuum and Line Strengths of Seyfert Galaxy NGC 4151

MU595 - M. H. Ulrich (Garching)
UV and Optical Observations of Active Nuclei: A Study of Non-Stellar Continous Radiation

MU597 - M. H. Ulrich (MU)
Continuation of the Monitoring of the Continuum and Line Strengths of the Seyfert Galaxy NGC 4151

MVDSL - David S. Leckrone (NASA/GSFC)
Spectroscopy of the EP, AP and Magnetic Variable Stars at Ultraviolet Wavelengths

MWOJL - Jeffrey L. Linsky (Colorado - JILA)
A Multiwavelength Campaign of Active Stars w/Intermediate Rotation Rates

NA004 - Howarth (UCL London)
Spectrophotometry of Magellanic Cloud B Main Sequence Stars

NA009 - Schonberner (Kiel)
UV Study of the Closest Central Star of a Planetary Nebula (S216)

NA013 - de Boer (Bonn)
Physical Parameters of Subdwarfs of Type SdOB and SdO

NA023 - Willis (UCL London)
High Resolution Spectroscopy of Magellanic Cloud WR Stars

NA024 - Willis (UCL London)
Multi-Wavelength Studies of HD 50896 (WN5+?) - Origin of its Stellar Wind Variability

NA026 - Monier (Vilspa)
Probing the Atmospheric Structure of 52 Her Through a Complete Phase Coverage in the Ultraviolet

NA030 - Prinja (UCL London)
Stellar Wind Variability in Mid-B Supergiants

NA032 - Weidemann (Kiel)
UV Spectroscopy of Selected White Dwarfs

NA035 - Fernley (Vilspa)
Radii and Bolometric Luminosities of Pleiades Main Sequence Stars

NA038 - Seggewiss (Daun)
Study of the Spectroscopic Magnetic Binary Alpha Dra

NA040 - Wolf (Heidelberg)
Chemical Abundances from B Stars in the Magellanic Clouds

NA041 - Wolf (Heidelberg)
B[e] Supergiants of the Magellanic Clouds

NA044 - Henrichs (Muenchen)
Multiwavelength Observations of Rapid Variable Be-shell Stars

NA046 - Henrichs (Muenchen)
UV and Optical Covariability of O Star Winds

NA048 - Krautter (Heidelberg)
Late Stages in the Outburst of Classical Novae

NA050 - Evans (Keele)
Ultraviolet Observations of PMS Stars in the Orion Region

NA064 - Heber (Kiel)
UV Spectrophotometry of Peculiar Hot Stars Discovered by the Hamburg Schmidt Survey

NA081 - Cacciari (Bologna)
UV-Bright Stars in M3

NA087 - Barstow (Leicester)
IUE Observations of DAB White Dwarfs

NA088 - Barstow (Leicester)
Time Resolved High Spectral Resolution Observations of a Rare DA + DM Binary System Which Also A Bright EUV Source

NA093 - Faraggiana (Trieste)
Search for Lambda Boo Stars

NA094 - Pottasch (Groningen)
IUE Observations of New Proto- Planetary Nebulae from IRAS Survey

NA098 - Faraggiana (Trieste)
The Chemical Composition of the Lambda Boo Stars

NA101 - Tjin A Djie (Amsterdam)
Evolution of the Envelopes of Herbig Ae/Be Stars

NA106 - Solheim (Tromso)
Two Phase Ultraviolet Spectrometry of Pulsating White Dwarf Stars

NA108 - Pottasch (Groningen)
IUE Observations of Post AGB Stars Which Show Spectrum Variation

NA118 - Vogel (Zurich)
Atmospheres of the Hot Components in Symbiotic Systems

NA128 - Heber (Kiel)
High Resolution UV Spectroscopy of 3 Metal Weak Lined SdO Stars

NA132 - Tweedy (Leicester)
A Scan Across the Planetary Nebula NGC 4361

NA141 - Willis (UCL London)
The Colliding Winds and Shocked Gas in Gamma Velorum (WC8+091)

NA154 - Bianchi (Torino)
Continuum and UV Extinction of OB Stars in M33 And M31

NA155 - Bianchi (Torino)
Study of Planetary Nebulae and Their Central Stars with IUE

NA157 - Bianchi (Torino)
Observations of Novae and Related Objects with IUE, ROSAT and Optical Telescopes

NA165 - Doazan (Paris)
The New Be Phase of Pleione

NA170 - Van der Hucht (Utrecht)
Colliding Winds and Dust Formation in the Variable WC7 Stars HD 192641 HD 193793 a Continuation Proposal

NA175 - Cassatella (Vilspa)
Verification of the IUE Flux Scale Through Observations of Two Hot DA White Dwarfs

NA186 - Talavera (Vilspa)
Stellar Winds and Mass Loss in A-type Supergiants

NA187 - Stahl (Heidelberg)
Multifrequency Observations of the Outburst Phase of the dLMC - LBV R127

NA188 - Catala (Meudon)
Cyclic Acitivity in PMS Herbig Ae Stars

NA192 - Parthasarathy (Bangalore)
Ultraviolet Spectrum of Extremely Metal Poor Post AGB Star HD 52961

NA193 - de Boer (Bonn)
Sorting Out Binarity in Hot Subdwarf Stars

NA201 - Koubsky (Ondrejov)
UV Spectra of the Cyclic Variable Shell Star HD 183656

NA202 - Megessier (Meudon)
Rotational and Short Time Scale Variations of the Magnetic Pulsating Ap Star And Alpha Cir

NA205 - Krautter (Heidelberg)
IUE Observations of the X-Ray Nova Muscae GRS 1121-68

NABJH - J. Patrick Harrington (Maryland)
An Investigation of Chemical Abundances in Low-Extitation Planetary Nebulae

NAERD - Reginald J. Dufour (Rice University)
Abundances of C, SI, & MG in Galactic H II Regions

NAESM - Stephen P. Maran (NASA/GSFC)
A Abundance in Planetary Nebula of Fornax Galaxy

NAGWF - Walter A. Feibelman (NASA/GSFC)
Atlas of Low and High Dispersion IUE Spectrograms of Planetary Nebulae and Related Objects

NASA- - Walter A. Feibelman (NASA/GSFC)
Hi-Res Study of PN-Nuclei of Extremely High Temperature & Low Luminosity

NASAY - George Sonneborn (NASA/GSFC)
Puppis SNR

NB108 - N. Bel (Meudon)
X-Ray Globular Clusters

NB423 - N. Bel (Paris)

A Very Rapidly Expanding Gas in the Core of the Globular Cluster NGC 6624
