- Apr. 1995
- Mar. 1995
- Feb. 1995
- Jan. 1995
- Dec. 1994

NASA IUE Newsletters

During the IUE Mission, the primary means to publish information needed by the users was the IUE Newsletters. Some of the articles will be helpful for archival users, such as those describing instrument performance, observing techniques, calibrations, and processing algorithms, while others are no longer relevant.

Currently we have available a text file, listing the tables of contents of all 57 newsletters. You can use the "Find" function of your web browser to search for specific names or other keywords.

Warning! There are over 600 articles listed!

NASA IUE Newsletters: Tables of Contents

We also have the newsletter articles scanned and available in PDF format. They have not yet been indexed and linked for easy access. However if you can determine the volume in which the article was published, you can view the papers in that volume:

IMAGE PROCESSING INFORMATION MANUAL

VERSION 2.0

Prepared for
GODDARD SPACE FLIGHT CENTER
By
COMPUTER SCIENCES CORPORATION
Under
Contract NAS 5-27295
Task Assignment 401

CSC/TM-84/6058
Prepared by: B. E. Turnrose and R. W. Thompson
Reviewd by: D. F. Stone and P. M. Perry
Date: December 20, 1984

ABSTRACT

This document presents information needed by users of the International Ultraviolet Explorer (IUE) to understand the methods and products of the new reduction software (introduced in November 1980 for low dispersion and November 1981 for high dispersion) of the IUE Spectral Image Processing System (IUESIPS) at GSFC. Although this Version 2.0 reflects the post-November 1981 state of IUESIPS and therefore describes the net effect of the many other changes made to the system since early 1980 when Version 1.0 was issued, its principal purpose is to document the new reduction software. As a result, Version 2.0 complements, but does not supersede, Version 1.0 or its reissue, Version 1.1.

September 1997

Computer Sciences Corporation

Abstract:

This document is intended for use by researchers who wish to analyze data acquired by the *International Ultraviolet Explorer* (*IUE*) and processed for the *IUE* Final Archive with the New Spectral Image Processing System (NEWSIPS) at either Goddard Space Flight Center (GSFC) or the European Space Agency (ESA) Villafranca del Castillo *IUE* Observatory (VILSPA). The information contained in this document explains the instrument characteristics and the processing methodology and calibration techniques used in the NEWSIPS system to produce the output products available to researchers. This second version of the *IUE* NEWSIPS Information Manual has been updated to include the processing techniques for LWR low-dispersion and LWP, LWR, and SWP high-dispersion data.

The EUVE Science Archive Data Products

The EUVE Permanent Archive

There are two components to the EUVE Permanent Archive: the EUVE Telemetry Archive and the EUVE Science Archive. The Telemetry Archive contains a complete copy of the raw telemetry from the entire EUVE mission, and is intended as a permanent record of the mission. It is not primarily designed to support scientific archival research and access to the data will be difficult because of the unprocessed nature of the telemetry. The EUVE Science Archive, however, is intended for scientific research and is what most people probably have in mind when they refer to the "EUVE archive".

The EUVE Permanent Archive was created at the Center for EUV Astrophysics (CEA). The data products in the archive have been delivered from CEA to the NSSDC for distribution to the astronomical community. EUVE Science Archive pointed data products are being made available through archive sites at STScI and the HEASARC. At the time of this writing, EUVE continues to perform Guest Observer (GO) observations of new targets. The data from these observations is periodically delivered by CEA to the NSSDC and becomes available to the public through the archive sites.

Archive Documentation

This document details several aspects of the Science Archive and its use. It is intended as an introduction to the Archive for users who are already familiar with the EUVE GO data products that have been delivered since the start of the GO program. A more complete set of documentation will eventually become available when the *EUVE Guest Observer Software User's Guide* and *EUVE Guest Observer Data Products Guide* are rewritten to describe the Science Archive. Until those documents are revised, they are still useful for their in-depth discussions of data reduction and instrumental issues, but with regard to details about data formats or analysis steps, the descriptions in this introduction should be considered more up-to-date. Archive data users unfamiliar with the previous GO data products might want to consult the earlier documents to understand terms mentioned but not fully described here.

Note that the *EUVE Science Archive User's Guide* that is mentioned in the comments in the archive data headers refers to the rewritten *EUVE Guest Observer Data Products Guide* and therefore is not yet available.

The Science Archive Contents

The EUVE Science Archive contains multiple types of data. During the first six months of the EUVE mission in 1992-1993, a survey of the EUV sky was performed. The maps and catalogs from this survey have been either published in the astronomical literature and/or made available from CEA for several years. These products are part of the Science Archive but are not discussed further in this introduction. Since the end of the survey, EUVE has been performing pointed GO observations. These observations are primarily done with the Deep Survey/Spectrometer (DS/S) telescope; a very small number of pointed observations have been done with the Scanner telescopes. The Science Archive contains event lists and images from all these pointed observations.

Data from pointed observations is delivered at the time of the observation to the GO to whom it belongs. In the past, after the expiration of the proprietary period of the data, CEA also made exact copies of the data sets available to archival researchers. All of the data products delivered from CEA were in a standard format (a mixture of FITS tables, FITS images, and IRAF QPOE files), now called the GO format. Between March 1997 and February 1998, all existing EUVE pointed observations were reprocessed at CEA and data sets were produced in a new format, the Science Archive pointed format. The reprocessing produced a uniformly processed set of observations for the Science Archive.

A side effect of the reprocessing is that there is not a one-to-one correspondence between the observations in the Science Archive and those delivered in the past to GOs and archival users. Some observations were split in pieces, while others were merged together. Where these differences exist, the new Science Archive definitions of the observations are to be considered more accurate (or at least more consistent).

The Science Archive Pointed Format

The Science Archive pointed format (also called the archive format) is substantially simpler than the format in which Guest Observer products were previously shipped (the GO format). The archived nighttime data for a single observation consists of two FITS files, named `events.fit` and `images.fit`. `Events.fit` contains the event and monitor data for the observation, while `images.fit` contains images and filtering data. Each FITS file contains multiple FITS image and/or binary table extensions, which will be described in detail below.

When daytime data is available for an observation, it is packaged in separate files named `events_day.fit` and `images_day.fit`. Daytime data is only available for the SW spectrometer, and only for observations taken before 15 March 1996 (a few earlier observations do not have day data).

Moving targets require more analysis steps than non-moving targets and contain some additional auxiliary data. The `events.fit` file for a moving target will contain two additional extensions with this additional data.

Occasionally, there is an anomaly during the observation or processing of a target that causes the resulting data to have unusual characteristics. When EUVE personnel noticed such an anomaly during the observation or its processing, written notes were appended to the FITS files in an additional binary table extension. We cannot ensure that the notes are comprehensive or always useful to researchers, but at least some information will be available if needed.

Next, we describe the contents of the archive FITS files in the nominal case. We use the abbreviations DS, SW, MW, and LW for the Deep-Survey imager and the Short-, Medium-, and Long-Wavelength spectrometers, respectively, and ScA, ScB, ScC for the Scanner A, Scanner B, and Scanner C telescopes.

Nominal contents of events.fit

Night DS/S data

- Primary HDU, empty

  The header of the primary header and data unit (HDU) contains keywords that are globally applicable to this observation. These keywords are also repeated in each extension. We don't use the INHERIT keyword mechanism supported by some FITS readers (i.e., the INHERIT keyword is always set to the value "F"). The primary data array is always empty.

- Extension 1, BINTABLE, extname = "valid_times"

  Contains the time intervals during which telemetry was present in this observation. The sum of the lengths of these intervals is also in the global keyword VALIDTIM. This is NOT the exposure time, because it does not account for times when the detectors were off. However, it does tell you an upper limit for the exposure time. There is no concept of exposure time for event list data in the absence of any time filters, because the possible arrival times for events are unrestricted. Therefore, no exposure times appear in the headers in `events.fit`. To see exposure times, look in `images.fit`.

- Extension 2, BINTABLE, extname = "ds_events"

  Contains the DS event list for this observation.

- Extension 3, BINTABLE, extname = "sw_events"

  Contains the SW event list for this observation.

- Extension 4, BINTABLE, extname = "mw_events"

  Contains the MW event list for this observation.

- Extension 5, BINTABLE, extname = "lw_events"

  Contains the LW event list for this observation.

- Extension 6, BINTABLE, extname = "quadrant"

  Contains quadrant-specific information for this observation. Only quadrants for which data is present in the event lists are included (except in the sums), meaning only one quadrant per detector in the archive. The information given for each quadrant is quadrant counts, telemetered counts, summed quadrant counts over all detector quadrants, deadtime correction, and combined deadtime & primbsch correction.

- Extension 7, BINTABLE, extname = "adcnts"

  Contains the detector A-D counts for each detector that has an event list in this observation.

- Extension 8, BINTABLE, extname = "orientation"

  Contains aspect and position information for the EUVE spacecraft during the observation.

- Extension 9, BINTABLE, extname = "corrected_aspect"

  Contains the corrected aspect for moving targets that have been corrected by an ephemeris. The extension is omitted if not needed.

- Extension 10, BINTABLE, extname = "ephemeris"

  Contains the ephemeris used to correct the aspect for moving targets. The extension is omitted if not needed.

- Extension 11, BINTABLE, extname = "anomaly"

  Contains a written description of any anomalies or other unusual characteristics of this observation that may impact the analysis of the data. The text is encoded as rows of a binary table with a single 80 character wide column. The extension is omitted if not needed.

The extension numbers are for the nominal case. The final three extensions are optional, and if data for any detector is, for some reason, not present for an observation, the corresponding extensions are simply omitted from the FITS files. Therefore, extension numbers may vary. However, the order of the extensions is always the same when they are present. Always check the contents of your FITS files before using them.

Day DS/S data

In daytime DS/S data, the format is the same as for night data except that only the SW spectrometer data is present. This means that only one event list extension (sw_events) is included and the quadrant and adcnts extensions contain only columns relevant to the SW spectrometer.

Scanner data

In scanner data, the format is the same as for night DS/S data except that the appropriate scanner detectors replace the DS and spectrometer detectors. There is never daytime scanner data.

Nominal contents of images.fit

Night DS/S data

- Primary HDU, empty

  The header of the primary HDU contains keywords that are globally applicable to this observation. These keywords are also repeated in each extension. We don't use the INHERIT keyword mechanism supported by some FITS readers. The primary data array is always empty.

- Extension 1, IMAGE, extname = "ds"

  Contains an image of the DS event list, made by binning the events in sky coordinates after applying filters.

- Extension 2, IMAGE, extname = "sw_night"

  Contains an image of the SW event list, made by binning the events in wavelength coordinates after applying filters.

- Extension 3, IMAGE, extname = "mw"

  Contains an image of the MW event list, made by binning the events in wavelength coordinates after applying filters.

- Extension 4, IMAGE, extname = "lw"

  Contains an image of the LW event list, made by binning the events in wavelength coordinates after applying filters.

- Extension 5, BINTABLE, extname = "ds_limits"

  Contains the filter limits used to produce the DS image in the ds extension from the event list.

- Extension 6, BINTABLE, extname = "sw_night_limits"

  Contains the filter limits used to produce the SW image in the sw_night extension from the event list.

- Extension 7, BINTABLE, extname = "mw_limits"

  Contains the filter limits used to produce the MW image in the mw extension from the event list.

- Extension 8, BINTABLE, extname = "lw_limits"

  Contains the filter limits used to produce the LW image in the lw extension from the event list.

- Extension 9, BINTABLE, extname = "anomaly"

  Contains a written description of any anomalies or other unusual characteristics of this observation that may impact the analysis of the data. The text is encoded as the rows of a binary table with a single 80 character wide column. The extension is omitted if not needed.

Day DS/S data

In daytime data, the format is the same as the night data except that only the SW spectrometer data is present; this means that only one image (named sw_day) and limits table (named sw_day_limits) are included.

Scanner data

In scanner data, the format is the same as for night DS/S data except that the appropriate scanner detectors replace the DS and spectrometer detectors. There is never daytime scanner data.

Description of Science Archive header keywords

This is a brief description of the header keywords that appear in the archive FITS files.

Standard FITS keywords

The following are standard FITS keywords with a standard meaning and are not described here: SIMPLE, BITPIX, NAXIS, NAXISn, EXTEND, DATE, ORIGIN, CREATOR, and END.

These are standard FITS keywords used to describe an extension and its structure (some are BINTABLE specific): XTENSION, PCOUNT, GCOUNT, TFIELDS, EXTNAME, TTYPEn, FORMn, TUNITn, TDISPn, TLMINn, TLMAXn, TDMINn, TDMAXn, TNULLn, and INHERIT.

These are standard FITS keywords used in images for scaling and world coordinate system information, or identification: BSCALE, BZERO, CTYPEn, CRVALn, CRPIXn, CDELTn, CUNITn, and FILENAME.

EUVE Science Archive keywords

- TELESCOP

  The name of the entire observatory, i.e., "EUVE".

- INSTTYPE

  The type of EUVE telescope/instrument that produced this data: "DS/S" or "SCANNER".

- INSTRUME

  The particular EUVE telescope/instrument that produced this data: "DS/S", "ScA", "ScB", or "ScC". In scanner data, this keyword varies for each event list.

- DETNAM

  The EUVE detector that produced this data: "ScA", "ScB", "ScC", "SW", "MW", "LW", or "DS". This keyword varies for each event list, since each detector's events are in a separate extension.

- PHOTOND

  This is a numerical detector number. It ranges from one to seven, corresponding to each of the detector values possible for the keyword DETNAM.

- TIMEDEL

For tables containing rows at regularly spaced time intervals, found in the quadrant, adcnts, orientation, and corrected_aspect extensions, this is the nominal interval length.

- OBJECT

  The name of the target. Note that many EUVE targets have been observed multiple times and were often proposed under differing names. A single name has been selected for each target and used consistently for all observations.

- RA_OBJ, DEC_OBJ

  The coordinates of the target, in decimal degrees, taken from the EUVE database. These are typically the coordinates the original Guest Observer specified, or coordinates taken from the SIMBAD database. For the DS or scanner detectors, the processed image is centered at these coordinates. For a moving target, these are the mean of the ephemeris coordinates during the observation.

- RA_PNT, DEC_PNT

  The median coordinates, in decimal degrees, at which the instrument was actually pointed during the observation. This will be different from RA_OBJ and DEC_OBJ if the observation was performed off-axis or for moving targets. Most EUVE observations are performed at least slightly off-axis to avoid the DS deadspot.

- RA_PROC, DEC_PROC

  The coordinates, in decimal degrees, that were used to process the spectrometer data. These are derived from a centroid of the image of the target on the sky as seen in the DS detector. Not all targets have a visible DS image - if the centroid could not be computed, RA_OBJ and DEC_OBJ are used in the spectrometer processing. In moving targets, this is always the same as RA_OBJ and DEC_OBJ.

- OBSERVER

  The original PI that had the rights to this observation. In some observations, multiple PIs were given the rights to the data, but only one PI is listed here. If this was a calibration observation without a PI, the keyword will have the value "EUVE". In some cases, calibration targets also had PIs but are listed as "EUVE".

- DATE-OBS, TIME-OBS

  The date and time (GMT) of the start of the observation. Note that the year assumes a prefix of 19.

- DATE-END, TIME-END

  The date and time (GMT) of the end of the observation. Note that the year assumes a prefix of 19.

- OBS_MODE

  The spacecraft pointing mode during this observation. For archive data, this will always be "POINTING". Other modes would apply, for example, in survey, or while the spacecraft was slewing between targets.

- DITHER

  The dithering mode during this observation: "DITHERED", "SPIRAL", or "NONE". Dithering is a procedure of slightly changing the pointing position during the observation to reduce the effects of fixed-pattern noise. There are two kinds of dithering done by EUVE: pointed dithers (including nodding) and spiral dithering.

- DETMODE

  The detector coordinate conversion mode during this observation: "WSZ" or "XY". The EUVE telemetry can contain raw WSZ coordinates or converted XY coordinates. This mode can change during an observation and is determined separately for each event. The value of this keyword represents the mode of the majority of the events in the observation (in all event lists) and not necessarily the mode of all events. The mode of an individual event can be determined by inspecting the PH (pulse height) column in the event list. Events in XY mode will have an undefined PH. The mode also affects the precision of time stamps on the events; see the discussion of the TIERRABS keyword.

- OFF-AXIS

  A Boolean flag indicating whether or not this observation was done primarily off-axis. This does not include small off-axis deviations due to dithering or DS deadspot avoidance.

- MOVING

  A Boolean flag indicating whether this was a moving target. If so, aspect correction will have been performed, and the `events.fit` file should contain the optional corrected_aspect and ephemeris extensions. When the target is moving, the meanings of the coordinate keywords are changed as described earlier.

- DAYNIGHT

  The telemetry type included in this observation: "DAY", "NIGHT", or "BOTH".

- VALIDTIM

  The sum of the lengths of the intervals in the valid_times extension, representing the total amount of telemetry which is present. This is NOT the exposure time, because it does not account for times when the detectors were off. However, it does tell you an upper limit for the exposure time. There is no concept of exposure time for event list data in the absence of any time filters, because the possible arrival times for events are unrestricted. Therefore, no exposure times appear in the headers in `events.fit`. In `images.fit`, the images have been made from filtered event lists, and the exposure times appear in the EXPTIME keyword.

- RA_UNIT, DEC_UNIT

  The units of the RA and DEC values that appear in other keywords. Always has the value "deg" in the archive.

- EQUINOX

  The equinox used for specifying coordinates in this observation. Always set to "2000." in the archive.

- RADECSYS

  The coordinate reference frame for this observation. Always set to "FK5" in the archive.

- TIMESYS

  The time system used to specify times in this observation. In the archive, this refers to the TIME columns that appear in a number of the tables, as well as the TSTART and TSTOP keywords. The value is always "MJD". Note, however, that EUVE times are not simply the MJD, but rather the number of seconds since some specific MJD; see the MJDREF keyword below.

- TIMEZERO

  An offset to be added to all EUVE event times to get their true time. This always has the value "0." in the archive, meaning that EUVE times are already in the time system described by the keywords TIMESYS, TIMEUNIT, MJDREF.

- TIMEUNIT

  The units of the EUVE times specified in this observation. This always has the value "s", meaning all EUVE times are in seconds since the time specified in the keyword MJDREF.

- CLOCKCOR

  A clock correction flag. Always has the value "NO" meaning that EUVE times are not guaranteed to be corrected to UT. Regular corrections are applied to the EUVE spacecraft clock to keep EUVE times near UT, but there is drift between corrections. The EUVE time is always kept within 0.9 msec of UT, and usually within 0.7 msec.

- TIMEREF

  Another time correction flag. Always has the value "LOCAL", indicating that EUVE times are in the time frame of the satellite, and are not corrected to the solar system barycenter or anywhere else.

- TASSIGN

  The location where times are assigned to EUVE event detections. Always has the value "SATELLITE", meaning that the times are assigned on the satellite.

- TSTART, TSTOP

  The start and end time of the observation, corresponding to the DATE_OBS, TIME_OBS, DATE_END, and TIME_END keywords described earlier, but in the EUVE time system rather than UTC.

- TIERRABS

  The precision of the EUVE times. For time tags on events, this depends on the coordinate conversion mode of the event (see the DETMODE keyword). WSZ mode events have time tags precise to 0.001 s, while XY mode events are only known to 0.008 s. In an event list, the TIERRABS keyword will have the value "0.001" or "0.008", depending on the DETMODE of the observation, but remember that timing of an individual event depends on the mode of that event. For a non-event-list table, the precision is always 0.001 seconds. The absolute EUVE time frame can drift slightly relative to UT, but the maximum drift is always smaller than the precision of the time tags; see the notes on the CLOCKCOR keyword above.

- MJDREF

  The reference time for all EUVE times. This always has the value "40000." for the archive, meaning that the EUVE times are in seconds relative to a zero point at MJD = 40000 (JD = 2440000.5, or 24.00 May 1968).

- EGOCSVER

  The EUVE processing software version used to produce this FITS file.

- REFVERS

  The EUVE reference calibration data set used to produce this FITS file.

- EXPTIME

  The exposure time for this image. This keyword appears in `images.fit` only and gives the exposure time for the image, corrected for the effects of primbsching and deadtime.

- RAWEXP

  The raw exposure time for this image. This keyword appears in `images.fit` only and gives the exposure time for the image, NOT corrected for the effects of primbsching and deadtime.

Description of FITS extensions

This is a description of the structure and meaning of all of the binary table and image extensions which can appear in Science Archive FITS files. No single FITS file will contain all these extensions. A table describing the columns of each binary table extension is given. The "Type" field refers to the FITS standard data types.

There are several categories of data in the binary table extensions. Event lists contain a row for every event detected by the EUVE detectors. Auxiliary values are reported in the telemetry at regular intervals during the observation, or derived from other auxiliary values or the event data. These values describe the state of the spacecraft or instruments. Other possibilities are time intervals, filter limits, or an ephemeris.

Events.fit extensions

valid_times

This is a binary table extension containing the time intervals for which telemetry was present during this observation. Each row contains the starting and ending times of a single time interval. The total time contained in all the intervals in this extension appears in the keyword VALIDTIM. The presence of telemetry does not imply that data is necessarily present in any detectors; for example, one or more detectors might be turned off. Therefore, these intervals do not represent the exposure time of the observation. The actual exposure time can only be defined by restricting the event lists to time intervals when the detectors were turned on. This is done during the processing of EUVE data when time filters based on A-D counts are applied in order to construct the images that appear in `images.fit`. See the discussion at the adcnts extension and the description of the EXPTIME keyword.

Column	Type	Units	Description
START	D	seconds	Starting time of interval.
STOP	D	seconds	Ending time of interval.

ds_events, sca_events, scb_events, scc_events

These are binary table extensions containing event lists for the EUVE imaging instruments. A separate extension is present for each detector that contained data for the observation. Each row of the table represents a single detected event.

Column	Type	Units	Description
TIME	D	seconds	Time of the event.
RA	D	degrees	Right ascension of the event.
DEC	D	degrees	Declination of the event.
DETX	I	pixel	Detector x-coordinate of the event.
DETY	I	pixel	Detector y-coordinate of the event.
PH	I		Pulse height of the event. This is only defined if the detector was in WSZ mode when this event arrived. See the discussion of the DETMODE keyword.

sw_events, mw_events, lw_events

These are binary table extensions containing event lists for the EUVE spectrometers. A separate extension is present for each detector that contained data for the observation. Each row of the table represents a single detected event.

Column	Type	Units	Description
TIME	D	seconds	Time of the event.
WAVELENGTH	E	Angstroms	The wavelength of the event.
ANGLE	E	degrees	The imaging angle of the event.
DETX	I	pixel	Detector x-coordinate of the event.
DETY	I	pixel	Detector y-coordinate of the event.
PH	I		Pulse height of the event. This is only defined if the detector was in WSZ mode when this event arrived. See the discussion of the DETMODE keyword.

quadrant

This binary table extension contains quadrant-specific auxiliary information for this observation, reported every 2.048 seconds, with occasional gaps in the data. The values in each row apply to the 2.048-second interval ending at the time of the row.

The columns that are present in this table vary; values are only included for quadrants which have potentially produced events in the event lists for this data set. A quadrant is (for our purposes) just a region of a detector over which quadrant counts are counted. EUVE detectors have one, two, three, or four quadrants. In most archive data sets, only one quadrant appears in this table for each detector: the quadrant that contains the source being observed. This is possible because in the DS/S instruments, sources are always observed in the same quadrants. These quadrants are SW: 0, MW: 1, LW: 1, and DS: 1. For pointed scanner observations, however, we cannot know the quadrant in which the source appears. Therefore, scanner data sets contain auxiliary values from all four quadrants for each detector present. The table below shows the columns you would expect to see in a DS/S observation with all detectors in use.

Quadrant counts are the total number of events detected in a detector quadrant during each 2.048-second interval, as determined on the spacecraft. The telemetered counts are the total number of events in a quadrant that appear in the telemetry as received on the ground. These two counts will differ due to loss of events during the telemetering process, typically due to insufficient bandwidth. The procedure by which events are selected for telemetering is called primbsching and the ratio of the quadrant counts to telemetered counts is called the primbsch correction. The summed quadrant counts are the sum of the individual quadrant counts for all quadrants of the detector, including those that do not appear in the table. This sum is used to determine the deadtime correction, a measure of the loss of events onboard the spacecraft due to deadtime in the processing hardware and software. Finally, the combined correction is the product of the deadtime and primbsch corrections.

Column	Type	Units	Description
TIME	D	seconds	Time for this row.
SWQ0SF	I	count	The quadrant counts in the SW quadrant 0.
SWQ0TM	I	count	The telemetered counts in the SW quadrant 0.
SWSUMQ	J	count	The summed quadrant counts over all SW quadrants.
SWDC	E		The SW deadtime correction.
SWQ0DPC	E		The combined SW deadtime and primbsch correction.
?	?	?	The last five rows repeat for every detector that is present in this observation, typically in the order SW, MW, LW, DS.

adcnts

This binary table extension contains auxiliary data that applies to an entire detector, reported every 1.024 seconds, with occasional gaps in the data. The values in each row apply to the 1.024-second interval ending at the time of the row.

The columns that are present in this table depend on which detectors are present in this data set. There will be one column containing A-D counts for each detector present

The A-D counts are hardware counts of the detections on each detector. They will differ from the summed quadrant counts for the same time interval because of filtering of events by the pulseheight threshold and loss of events due to deadtime in the detector electronics. A-D counts are used to detect whether a detector is on or off; three or more counts in a 1.024-second interval is normally taken to indicate that the detector is on. A-D counts can also be used for data-quality filtering, such as removal of times of high background.

Column	Type	Units	Description
TIME	D	seconds	Time for this row.
SWADCT	I	count	The A-D counts in the SW spectrometer.
MWADCT	I	count	The A-D counts in the MW spectrometer.
LWADCT	I	count	The A-D counts in the LW spectrometer.
DSADCT	I	count	The A-D counts in the DS detector.

orientation

This binary table extension contains auxiliary data describing the position and orientation of the EUVE spacecraft, reported every 1.024 seconds, with occasional gaps in the data. The values in a row apply at the instantaneous time of the row. Note that the row times in the orientation table are not exactly the same as those in the adcnts table.

The columns in this table are independent of which detectors have data in this data set, and are always as shown below.

The orientation information appears as the four components of a quaternion (the aspect) which represents the rotation from J2000 equatorial coordinates to a coordinate system fixed with respect to the spacecraft. For more details of the use of the aspect quaternion and additional references, see Abbott, *et al.* 1996, ApJS, **107**, 451. If this is a moving target and the aspect has been corrected for the motion of the source on the sky, an additional binary table extension named corrected_aspect will be present in this data set. The position information appears as the Cartesian coordinates of the spacecraft in the J2000 equatorial frame, in units of meters. The length of the position vector yields the spacecraft altitude.

Column	Type	Units	Description
TIME	D	seconds	Time for this row.
ASPECTW	D		Quaternion component.
ASPECTX	D		Quaternion component.
ASPECTY	D		Quaternion component.
ASPECTZ	D		Quaternion component.
POSITIONX	D	meters	J2000 equatorial spacecraft position component.
POSITIONY	D	meters	J2000 equatorial spacecraft position component.
POSITIONZ	D	meters	J2000 equatorial spacecraft position component.

corrected_aspect

This optional binary table extension is equivalent to the aspect portion of the orientation extension, except that the aspect values have been corrected for the motion of the source on the sky. This extension only appears for moving targets. The correction uses the source position information in the ephemeris extension.

Column	Type	Units	Description
TIME	D	seconds	Time for this row.
ASPECTW	D		Quaternion component.
ASPECTX	D		Quaternion component.
ASPECTY	D		Quaternion component.
ASPECTZ	D		Quaternion component.

ephemeris

This optional binary table extension contains an ephemeris for the source during this observation. This extension only appears for moving targets. The values on each row apply to the instantaneous time of that row. The frequency of tabulated points will vary.

The positions in this ephemeris represent the J2000 coordinates of the target as seen from EUVE, including any significant parallax effects. These positions are used to correct the aspect values for this observation to account for the motion of the source on the sky. The corrected values appear in the corrected_aspect extension.

Column	Type	Units	Description
TIME	D	seconds	Time for this row.
RA	D	degrees	Target right ascension.
DEC	D	degrees	Target declination.
DIST	D	AU	Target geocentric distance.

Images.fit extensions

ds, sca, scb, scc

These are image extensions containing images constructed by binning the detector event lists in remapped (sky) coordinates. RA is increasing along the x-axis and Dec is increasing along the y-axis. The event data is filtered using time filters constructed from the limits specified in the corresponding table extension (ds_limits, etc.).

sw_night, mw, lw

These are image extensions containing images constructed by binning the detector event lists in remapped (spectral) coordinates. Wavelength is increasing along the x-axis and imaging is increasing along the y-axis. The event data is filtered using time filters constructed from the limits specified in the corresponding table extension (sw_night_limits, etc.).

ds_limits, sw_night_limits, mw_limits, lw_limits

These binary table extensions contain limits on auxiliary data values that are used to filter event data for the observation when constructing images. This filtering removes earth-blocked times, times of high background, and times when the detectors were turned off.

Column	Type	Units	Description
NAME	A		Name of limited value.
LOW	E	unknown	Lower limit.
HIGH	E	unknown	Upper limit.

Common extensions

anomaly

This optional binary table extension contains a varying number of rows of text describing any anomalies in the data that were noticed during the observation or processing of this target. The extension only appears when needed. The comments are subjective in nature and are not guaranteed to be complete or useful.

Column	Type	Units	Description
TEXT	A		

Working With Science Archive Data

The archive format has been designed primarily as a FITS format. That means that considerable care has been taken to make the FITS files well organized and easily understood, and to provide complete meta-data in the headers. This means that the data is now much easier to read and manipulate using ordinary FITS tools. This is especially helpful to users who wish to bypass the IRAF file formats used in the EUV package and do their analysis in a non-IRAF environment. The description of the headers and tables given earlier should be sufficient for such users.

On the other hand, those users who wish to use the EUV package, or simply return to more familiar products, will have to reconstruct those products from the archive FITS files. Here are step-by-step instructions to unpack your data and reproduce the basic analysis steps, using IRAF and the EUV software package. The resulting products are very similar to the products that were delivered in the old GO format.

Note that the new procedure is rather different from the one you may have used in the past to unpack GO format data. In particular, you no longer need to use the EUV package task **qprst**.

IRAF releases and the EUV package

At the time of this writing, the most recent publicly available version of the EUV software package is version 1.7. That version of the EUV package is compatible with IRAF 2.10.4, but not with the most recent IRAF release, 2.11. Release 1.8 of the EUV package will work with IRAF 2.11.

This document is applicable to either version of the EUV package. In the instructions below, where parameter lists are shown for IRAF tasks, they will be the IRAF 2.11 versions (any differences are minor). The same instructions can be used with IRAF 2.10.4/EUV 1.7, but you need to refer to unpacked ST tables and IRAF images, as described in the next section, rather than FITS extensions.

Referring to tables and images

If you are using IRAF 2.11/EUV 1.8, you have several options available regarding the method you use to access the tables in your data set. Under IRAF 2.11, image and table processing tasks can directly read FITS image and binary table extensions. Several software tasks described below require tables from the data set as input. You can either unpack the FITS files into a one or more standalone ST tables, which you then specify as input where needed, or you can specify individual FITS binary table extensions directly as input to the software.

If you choose to use the FITS extensions directly, you have two ways to refer to a specific extension: by number, or by name. The extensions are numbered starting at one. This is probably most easily illustrated with a specific example. Let?s assume you have unpacked your event file `events.fit` into individual ST tables using the method described below (the FITS file is assumed to have the nominal DS/S night contents described earlier). You therefore have an ST table named `ds_events.tab` in the current directory (as well as several other tables) and you also still have the original FITS file. You now need to specify the DS event list to a program. The following are all legal references to the DS event list:

`ds_events.tab`	Read the unpacked ST table.
`ds_events`	Same as the previous example. The ".tab" filename extension is assumed if not present.
`events.fit[extension=2]`	Read directly from the second extension in the FITS file.
`events.fit[2]`	Same as the previous example. A number is assumed to refer to an extension number.
`events.fit[extname=ds_events]`	Also reads from the second FITS extension, this time selecting the extension by name.
`events.fit[ds_events]`	Same as the previous example. Any word not otherwise meaningful is assumed to refer to an extension name.

We will always use the last of these methods of specifying a table in the code examples below. You can choose another if it is more convenient. Also, keep in mind that the files don?t have to be in the current directory; you can specify the path to the file if needed.

There is one additional complication: the IRAF CL will try to interpret certain characters specially if you do not prevent it. In particular, it won?t like the "=" (equals sign) character in the above examples. So when typing an expression on the command line, you either can quote the entire expression (using single or double quotes), or escape the equals sign, as in

```
?events.fit[extname=ds_events]?
```

or

```
events.fit[extname\=ds_events]
```

Of course, you can also avoid this problem by using one of the table references that doesn?t contain an equals sign, or by entering your parameters in the IRAF **epar** utility, where they are not interpreted by the CL.

Important IRAF 2.10.4 note: If you are using IRAF 2.10.4, directly reading from a FITS file is not possible. You must always unpack your FITS files as described below and then refer to the ST tables using one of the first two methods in the above table.

Unpacking your FITS files

Convert the FITS extensions into ST tables and IRAF images. This step is optional when using IRAF 2.11/EUV 1.8, but required under IRAF 2.10.4. The conversion can be done using the **strfits** task in the TABLES package. Set up your parameters like this:

fits_files = ""	FITS data source
file_list = ""	File list
iraf_files = ""	IRAF filename
(template = "none")	template filename
(long_header = no)	Print FITS header cards?
(short_header = yes)	Print short header?
(datatype = "default")	IRAF data type
(blank = 0.)	Blank value
(scale = yes)	Scale the data?
(xdimtogf = no)	Transform xdim FITS to multigroup?
(oldirafname = yes)	Use old IRAF name in place of iraf_file?
(force = yes)	Force conversion from fits?
(offset = 0)	Tape file offset

The essential parameter is `oldirafname,` which should be set to "yes", causing the newly created tables and images to have the same names as the FITS extensions they came from. Change to a directory where you want the unpacked products to appear. To unpack all of the extensions in a FITS file, run **strfits** using command lines like

```
cl> strfits events.fit 1 ""
```

and/or

```
cl> strfits images.fit 1 ""
```

where you replace the pathname of the FITS files with whatever is correct for the observation in your system. The FITS files need not be in the current directory; simply supply the full path (they can even be on a CDROM). Obviously, if you don't require both the event lists and images you need only unpack one of the FITS files.

To unpack only a single extension, specify the desired extension by number, such as

```
cl> strfits images.fit[1] 1 ""
```

Alternatively, you can simply copy the extension out using the **tcopy** task for a table, or the **imcopy** task for an image, which also conveniently allows you to specify the extension by name:

```
cl> tcopy events.fit[ds_events] ds.tab

cl> imcopy images.fit[ds] ds.imh
```

In addition to producing an ST table for each BINTABLE extension and an IRAF image for each IMAGE extension in the FITS files, **strfits** will leave behind an image named `tmp001.imh` or something very similar. This is an empty image representing the contents of the Primary HDU, which contains no data in EUVE archive files. You can safely delete that image if you wish.

Building IRAF data files

1. Reconstruct a QPOE file for an event list. At this point, you have either unpacked an event list from `events.fit` using the previous step, resulting in an ST table, or you are running IRAF 2.11/EUV 1.8 and you are working directly from the FITS file. The reconstruction is done using the task **cep** in the EUV package.

   We assume that you have a subdirectory (or a link to a directory) in your current directory named `reference` that contains an installed copy of the EGODATA reference data set. You must have EGODATA version 1.15 or later, since that version contains new **cep** scripts for working with archive data.

   Spectrometer data

   To build a spectrometer QPOE file, set up the parameters for the task **cep** as follows:

database = "reference/archpipe"	Processing text database name
pipeline = "Rebuild SW Spectrometer Archive QPOE"	Pipeline record name
(ra = INDEF)	Source right ascension
(dec = INDEF)	Source declination
(raunits = "degrees")	Units for RA [degrees|hours]
(tableindex = "")	Observation table index file
(events = "events.fit[sw_events]")	Observation event list table
(aspect = "")	Observation aspect table
(reference = "")	CEP reference file

   The key parameters here are `database`, which we have set to point to a special pipeline database used for working with archive data; `pipeline`, which identifies the specific script **cep** will execute; and `events`, which identifies the input event list. All other parameters can be left at their defaults.

   If you are building an MW or LW spectrometer QPOE, rather than SW, you need to change the `pipeline` parameter to refer to the appropriately named script, and change the `event` parameter to refer to the appropriate event list.

   Non-moving imaging data

   If you are building a non-moving imaging QPOE (DS or scanner), rather than a spectrometer, you need to change `pipeline` and `events`. You must also enter the coordinates at which the QPOE should be centered. The parameter setup for **cep** for a DS QPOE would resemble this:

database = "reference/archpipe"	Processing text database name
pipeline = "Rebuild DS Remapped Archive QPOE"	Pipeline record name
(ra = 123.45)	Source right ascension
(dec = 67.89)	Source declination
(raunits = "degrees")	Units for RA [degrees|hours]
(tableindex = "")	Observation table index file
(events = "events.fit[ds_events]")	Observation event list table
(aspect = "")	Observation aspect table
(reference = "")	CEP reference file

   You can enter any `ra` and `dec` at which you would like the QPOE centered. However, if you want to exactly reproduce the processing done at CEA, enter the values from the RA_OBJ and DEC_OBJ header keywords for the observation in question (dump the header of any table or image to see those).

   For the scanner detectors, simply substitute the appropriate pipeline script: ScA, ScB, or ScC instead of DS.

   Moving imaging data

   If you are building an imaging QPOE (DS or scanner) for a moving target, the only change from a non-moving imaging target is that you should use the "SourceCentered" `pipeline` script, as shown in this example parameter setup:

database = "reference/archpipe"	Processing text database name
pipeline = "Rebuild DS SourceCentered Archive QPOE"	Pipeline record name
(ra = 0.)	Source right ascension
(dec = 0.)	Source declination
(raunits = "degrees")	Units for RA [degrees|hours]
(tableindex = "")	Observation table index file
(events = "events.fit[ds_events]")	Observation event list table
(aspect = "")	Observation aspect table
(reference = "")	CEP reference file

   In this case, you almost certainly want to supply an `ra` and `dec` of (0., 0.) so the center of the QPOE is the center of the source.

   Those of you familiar with the EUV package and **cep** task will be glad to know that, when used for rebuilding a QPOE as described here, **cep** runs more quickly than during a reduction from raw data. This is because no calculations need to be performed. The running time will depend on the number of events in the event list.

   The **cep** rebuild scripts do not support the rebuilding of multiple QPOE files at once because in this usage the input comes from a different file or extension for each event list; you will have to run **cep** once for each detector.

2. If you want to recreate the filters that were used to produce the images in the archive from the event lists, you will first need to build the earth blockage table using the EUV package task **backmon**. Assuming you have the EGODATA data set in the `reference` subdirectory as described in step 1, the parameters should be set up as

output = "backmon"	Name of output ST table
(orient = "events.fit[orientation]")	Name of input orientation ST table
(refdata = "reference/detector")	Name of ST table for reference data
(detectors = "ds")	Detector (for boresight quaternions)
(skip = 1)	Number of rows to skip over
(maxtimegap = 600)	Max gap in time (secs) for Sat. Vel. Vectors
(time = "time")	Time column of orientation table
(aspectw = "aspectw")	Aspect W input column name
(aspectx = "aspectx")	Aspect X input column name
(aspecty = "aspecty")	Aspect Y input column name
(aspectz = "aspectz")	Aspect Z input column name
(posx = "positionx")	Position X input column name
(posy = "positiony")	Position Y input column name
(posz = "positionz")	Position Z input column name

   The default parameter values are set up for GO format products and must be changed slightly for archive format. The parameter `time` should be given the value "time". The parameter `detectors` can, for computing earth blockage, be set to any detector of the same instrument type, so "ds" is a valid value for any of the DS/S detectors. The parameter `skip` determines the time frequency of computed values-the value "1" will give the most accurate determination of earth blockage (one point per 1.024 seconds). The parameter `orient` should refer to the table containing EUVE position information.

   Next, you use the EUV package task **dqselect** to generate the time filters. The parameters can be set up like this:

tables = "events.fit[adcnts],events.fit[quadrant],backmon"	Monitor Tables	
(limits = "")	Limits Tables	
(gap = 1)	Time Gap	
(imode = "line")	Input mode	
(format = "14.4f")	Interval format control	
(device = "stdgraph")	Graphics device	

   where the important parameter is `gap`, which should have the value "1". This indicates that any intervals of missing data larger than the nominal interval spacing will cause a break in the filter. **Dqselect** is an interactive task, so you can run it and use a session like this:

   ```
   eu> dqselect

   Command> limload images.fit[sw_night_limits]

   Command> gtgen

   Command> gtsave sw_gt

   Command> q
   ```

   This produces the table `sw_gt` containing the filter intervals when the detector was on and not earth-blocked, by filtering on the SW A-D counts and the DS/S look-zenith angle. If you want to see the particular monitor limits that were used to make the filter, dump the contents of the sw_night_limits table in `images.fit`. This example is for the SW spectrometer; you could do any other spectrometer by loading the appropriate limits file with the `limload` command and using an appropriate name with `gtsave`.

   There appears to be a bug lurking in the **dqselect** program that causes it to sometimes fail when the `limload` command is run directly on a FITS file as in the example above. If this happens to you, the best solution is to unpack the limits file from the FITS file into an ST table before loading it into **dqselect**. For example,

   ```
   eu> tcopy images.fit[sw_night_limits] sw_night_limits.tab

   eu> dqselect

   Command> limload sw_night_limits
   ```

3. Add the time filter to the QPOE file as a macro. This step makes the filter available for use in QPOE expressions. The task **tfilter** can be set up like this:

input = "sw_gt"	Input table name
(output = "sw.qp")	Output file
(name = "sw_gt")	Name of output macro
(start = "stime")	Name of starting column
(start = "etime")	Name of ending column
(cmdline = no)	Command line output flag
(format = "14.4f")	Interval format control

which will cause the ST table `sw_gt.tab` to be read and the intervals written in the QPOE file `sw.qp` as the macro named `sw_gt`.

If you want to see a list of the macros which are defined in your QPOE file, and their values, use

```
eu> qpmedit sw.qp * .
```

4. The final step is to create an image by binning the event list. The task **qpmkim** is used for that purpose.

input = "sw.qp[time=(sw_gt)]"	QPOE file
output = "mysw.imh"	Image file
(corrtab = "events.fit[quadrant]")	correction table name
(refdata = "reference/detector")	reference directory
(applycorr = yes)	apply correction
(adjexptime = yes)	adjust exposure time
(errband = no)	create error band
(deadtime = yes)	do deadtime correction
(primbsch = yes)	do primbsch correction
(timecol = "")	optional alternate time column name
(corrcol = "")	optional alternate correction column name
(tepsilon = INDEF)	alternate epsilon value used for time comparison
(deltime = INDEF)	alternate delta of correction times
(detector = "")	detector name
(quadrant = INDEF)	source detector quadrant [INDEF or 0-3]
(infomsgs = yes)	give processing information messages
(fixmwcs = yes)	apply QPOE mwcs workaround fix
(timefield = "time")	QPOE event time field
(dxfield = "dx")	QPOE event dx field
(dyfield = "dy")	QPOE event dy field

The *`input`* parameter specifies the QPOE file to bin and a time filter to apply. The parameter *`corrtab`* refers to the table containing the primbsch and deadtime correction values. **Qpmkim** will determine which detector it is processing from the QPOE header keywords, and use the appropriate column from the correction table. The exposure time will be written into the image header.

The resulting image will be exactly equivalent to the corresponding image in the `images.fit` archive file. We have noticed that a very small number of events are sometimes shifted by one pixel in the images rebuilt with the procedure described here, versus the image taken straight from the archive. The shift is always along the x-axis (RA) and is most likely caused by a roundoff error at some point in the processing. (By the time you run **qpmkim**, the event list has been converted from a QPOE to an ST table to a FITS binary table and back to a QPOE).

Changes From Previous Guest Observer Data

Comparison to GO format

Users familiar with the format previously used to deliver EUVE Guest Observer and Archive data (referred to as the "GO format") will initially find the new format to be rather different. The new format has been designed from the start as a FITS format for EUVE data. That means that all design decisions have been made with the goal of producing FITS files that are portable and compatible with other standards or conventions for delivering event data as FITS.

Within those restrictions, however, the format has been designed to be as backwardly compatible as possible with the GO format. This means that the FITS files can be unpacked to ST Tables and QPOE files can be rebuilt. The resulting set of files will resemble the equivalent files in the GO format. In addition, all tasks in the EUV/IRAF analysis package have been modified (as of version 1.7) to work with both GO & archive data formats with little change from the user's point of view.

More subtle than the data format changes are changes to the science content of the data. These have been made to try to accommodate the majority of scientific uses of the data while minimizing the size of the archive. The changes also attempt to maximize the utility of more reduced products such as images. This lessens the likelihood that a researcher will need to work with the less reduced event list products, since the latter are larger and more complex.

These are the most significant changes:

- The archive data products do not contain the complete raw telemetry for the observation. In particular, they do not contain all events that were detected during the observation. For those events which are delivered, we still provide both remapped and detector coordinates, so that the data may still be reprocessed. However, in the GO format, it was possible to go to the raw data in the ST Tables to get access to events that were stripped out of the QPOE files. This is no longer possible. For example, there is no access to the stimpins in the spectrometers.
- In the spectrometers, we still deliver only events in a strip in remapped coordinates. The strip has now been narrowed from Y=720:1299 to Y=875:1174 (about 22 arcmin). For extended sources for which the strip would render the data less useful, we make an exception and open the strip to Y=1:2048 (the whole field of view).
- In the DS data, while we still process only events in the Lexan quadrant, we no longer deliver only a horizontal strip of events in the range Y=720:1299 in remapped coordinates. All events in the Lexan quadrant are now included in the event list and image.
- The vast majority of engineering monitors-the columns in tables 1-8 in the GO format-have been dropped. Only those monitors which are believed to be in common use for data analysis will be in the archive: aspect, position, quadrant counts, and A-D counts (along with primbsch/deadtime information).
- The monitors have been reorganized. The quadrant extension contains quadrant counts previously in table2 and primbsch and deadtime info previously in the primbsch table. The adcnts extension contains A-D counts previously in table1. The orientation extension contains aspect and position information previously in table1.
- The event list FITS extensions are sorted by time, whereas the QPOE files in the GO format were sorted by position.
- In event lists containing sky coordinates, we have changed the RA values to be in the range 0 to 360 degrees. In previous data, it was in the range -180 to 180 degrees.
- All event lists now contain pulse height information for each event for which it was available (meaning all events taken in WSZ mode).
- The header keywords in the tables and images have been completely reworked to meet FITS standards or guidelines from the HEASARC for event list data. In particular, the cards JDREF, OBSERVAT, and PI_NAME have been deleted. The cards INSTRUME, TELESCOP, TIMESYS, and ORIGIN now have different values. And many, many new cards have been added.
- The data types of some table columns have changed from floating point to integers: primarily all the counts in the quadrant extension.
- The DS image we produce has now been filtered with an upper limit on the quadrant counts in quadrant 1 (the Lexan filter). The upper limit is 50 counts per two frames for all but a handful of the brightest DS sources; for those, we increase it to 150. In GO format data, there was no upper limit in the DS count rate filter.
- For moving targets, we now use an ephemeris to correct the aspect for the motion of the target on the sky. The ephemeris and the corrected aspect values are included with the observation data set.
- For some moving targets, in addition to the strips of events mentioned above, we also remove events in certain portions of the detector specified in detector coordinates, such as the stimpins and unused quadrants. This is to prevent these detector features from being smeared all over the image of the source due to the large source motion on the detector.

Frequently Asked Questions

Why is the extension containing SW spectrometer data named sw_night in `images.fit`, but only sw in `events.fit`?

> When the archive format was originally designed, we considered the possibility that the sites delivering archive data would wish to combine the night and day image data into a single FITS file. This could be convenient since those products are presumably the most commonly desired for any observation. In order to support this, we had to give the SW spectrometer day and night data different extension names. To date, no such combined delivery is being done, as far as we know, but it is still supported.

Where is the DISPAXIS header keyword that **euvextract** complains is missing from my image?

> The old GO format products had a header keyword named DISPAXIS in each spectrometer image. This keyword is used by some spectral analysis programs in IRAF to identify the orientation of the spectrum; for example, it is used in the extraction program **euvextract** in the EUV package. Because the keyword was specific to certain analysis programs, we omitted it from the archive image headers.
>
> If you need to use such a program, you can add the keyword to the image using the IRAF task **hedit**. For nominal EUV spectra, the value of the keyword should be "1", indicating that the spectrum lies along the x-axis. The **euvextract** in particular has been modified in version 1.8 of the EUV package to have an additional parameter which allows you to specify the dispersion axis without having to add a keyword.

How do I see the ephemeris used in my moving target analysis before parallax corrections were applied?

> Unfortunately, this is not possible. The archive products for moving targets include the ephemeris after the application of parallax corrections for the position of EUVE (applied using the EUV package task **parallax**). There is no simple way to remove those corrections. In hindsight, this was a poor decision. It would have been better to include the raw ephemeris, since users could always have reapplied the parallax corrections using the **parallax** task and the orientation table.

How can I rebuild QPOE files for all of the event lists at once?

> You cannot. The rebuild scripts for **cep** are only capable of functioning on one event list at a time. This is a limitation of the **cep** program (it can only read from one table) and cannot be reasonably worked around.

Where are the extracted spectra?

> No extracted spectra are part of the EUVE Science Archive. This was done because automatic extraction of spectra during the pipeline processing of observations at CEA is very unreliable. EUVE spectral images typically have a very low background, and many spectral sources are faint and are composed of discontinous spectral lines. These features make it very difficult for tracing algorithms to find the spectra on the images. In addition, flexure of the instrumentation means we cannot know in advance precisely where the spectrum will fall on the image in every case. Because of these reasons, we do not automatically produce extracted spectra, and resource limitations did not allow hand extraction of spectra for the archive.
>
> The archive sites may in the future make available quick-look spectra that are produced during processing using the assumption of no flexure and a perfectly straight spectrum. However, in many cases these spectra are known to be inaccurate. They also are not subject to the same quality control as the event and image data. If you obtain such spectra, please use them extreme caution-they are for quick-look purposes only and should not be used for analysis. You should always do science with spectra that have been hand-extracted from the images.

        ELECTRONIC NEWSLETTER OF THE EUVE OBSERVATORY
-----------------------------------------------------------------
```

The EUVE Electronic Newsletter was published quarterly by the EUVE Science Archive group and contained information on a variety of mission-related topics (e.g., science discoveries, the Guest Observer Program and the Science Archive). As events warranted, periodic news "flashes" were distributed to convey urgent and/or time-critical information. Past issues of the newsletter, along with some of the major highlights for each, are available below.

Past Issues of the EUVE Electronic Newsletter:

2000 Issues:

- 02 October 2000 (V9.2) -- NASA Senior Review Terminates EUVE Mission; Senior Review Results Trigger EUVE End-of-Mission Activities; Survey Shows High Levels of EUVE GO Satisfaction; EUVE Team Received Award from NASA Administrator; EUVE FOT Implements Complicated Observation of Comet LINEAR; EUVE and Chandra Team Discover Charge Exchange Emission from Comet LINEAR; First with EUVE: Observation of Sharp Turn-on in Flux between Her X-1 Short High and Low States; EUVE Catches OY Car in Superoutburst; and EUVE Results from XTE J1118+480.
- 18 July 2000 (V9.2) --UCB Celebrates EUVE 8-year Launch Anniverary; EUVE Science Session well attended at June AAS; EUVE Battery Failure Prompts Safe-Hold Mode Entries; EUVE Coordinated TOOs of New X-Ray Transient; UCB Submits EUVE Proposal to Senior Review; UCB Celebrates 3-Year Outsourcing Anniversary; EUVE Conducts Innovative TOO Collaboration with AAVSO; UCB Released New Version of EUVE Data Analysis Package.
- 09 February 2000 (V9.1) -- Battery dVs Trigger EUVE Entry into Safe-Hold Mode; FOT Adjusts EUVE Frequency; Update on 1999 EUVE Archival Data Demands; EUVE Releases Science Recalibration Results; EUVE FOT Continues Active Battery Management; EUVE Cycle 8 TAC Results; and EUVE Science Advisory Board Public Meeting Held.

1999 Issues:

- 11 October 1999 (V8.2) -- EUVE set to destaff weekends; EUVE Science Advisory Board (ESAB) to hold public meeting at AAS January meeting; findings on Her X-1, G191-B2B, and discovery of AM Her star EUVE J0425.6-5714; EUVE Episode 8 proposals due October 13, 1999
- 03 August 1999 (V8.1) -- EUVE completes "Lessons Learned" report; EUVE Science Advisory Board (ESAB) submits FY98 report to NASA; EUVE project prepares to release Announcement of Opportunity for an eighth observing cycle

---

1997 Issues:

- 23 December 1997 (V7.12) -- EUVE Observers U Gem as TOO; GO Support Being Folded Into Operations

  Note that this issue of the EUVE electronic newsletter will be the last published on a monthly basis; beginning in 1998 distributions will be continued as events warrant (e.g., on a quarterly basis). This publication change is in response to the continued shrinking of available EUVE mission staffing and budgetary resources.

- 26 November 1997 (V7.11) -- NSSDC To Take Over EUVE Archival Data Delivery; EUVE Conducts Reaction Wheel Assembly Tests; IP Transition Proceeding
- 31 October 1997 (V7.10) -- Cycle 6 Announcement of Opportunity; Proposal Review Process for Cycle 6; FDF Sees Unexpected Decrease in EUVE's Velocity
- 29 September 1997 (V7.9) -- ESAB Meeting to be Broadcast Live on Internet; EUVE/ALEXIS Transient Reobserved; UCB Makes Progress on PACOR Replacement
- 31 August 1997 (V7.8) -- EUVE Science Program Management Changes; ALEXIS "Bastille Day" Transient; Observation of P/Encke; FOT Successfully Implements Payload ATCs
- 31 July 1997 (V7.7) -- EUVE Celebrates Five Years in Orbit; EUVE Offers Coordinated Observations to XTE/ASCA Proposers; EGO Center Releases New Software and Calibration Data; DS/S Calibration Observation of HZ 43; New TPOCC Software Release Delivered
- 27 June 1997 (V7.6) -- EUVE TPOCC Software Delivery Plan Set; UCB/CEA Software Development Milestones; Farewell to George Kaplan
- 2 June 1997 (V7.5) -- List of Approved Cycle 5 Proposals; EUVE Data Delivery Resumes; Subsystem Trending Begins Again; UCB Receives Additional Services from NCC; GFE Shipment Completed; DSN Test Conducted Successfully
- 30 April 1997 (V7.4) -- EUVE Under New Management; TOO to ALEXIS Transient; New Data Service to EUVE Observers; UCB Assumes Operational Contol of EP Spacecraft
- 1 April 1997 (V7.3) -- UCB-CEA Begins Realtime Operations of EP Spacecraft; EUVE Target of Opportunity: T Leo; Extended Survey Period for Spacecraft Calibrations; UCB-CEA Handles Its First Spacecraft Anomaly; Commencement of Phase 2 "Realtime" Shadow Operations
- 22 February 1997 (V7.2) -- EUVE GO Cycle 5 Proposals Due; Call for Reviewers; EUVE Stellar Spectral Atlas
- 31 January 1997 (V7.1) -- EUVE Spacecraft in Safe-Hold Mode; Mission Operations Review at GSFC; CEA FOT Fully Staffed; EPOC Systems Testing

---

1996 Issues:

- 27 December 1996 (V6.12) -- Upcoming Release of Cycle 5 NRA; Call for Proposals for EUVE RAP Program; New Contact Information for EUVE Observatory
- 30 November 1996 (V6.11) -- EUVE Episode 5 NRA; NASA SEUS Strategic Planning; Notice To GOs On Turn-Off of EUVE Scanner C
- 29 October 1996 (V6.10) -- EUVE Observations of AR Lacertae; EPOC FOT hiring and training; Science Education notes
- 30 September 1996 (V6.9) -- EUVE Observations of EUVE J0720-317 and EUVE J0723-277; Safe-Hold Event Summary; Formation of EUVE Science Advisory Board
- 30 August 1996 (V6.8) -- EUVE Observations of AU Mic, and EUVE Outsourced Extended Mission Status Report
- 29 July 1996 (V6.7) -- EUVE Observations of RX J0437.4-4711, AM Herculis, and CF Tucanae.
- 29 June 1996 (V6.6) -- FIP effect in Epsilon Eridani; Initial release of RAP data.
- 31 May 1996 (V6.5) -- EUVE Observations of the Bright Comet B2 1996 (Hyakutake)
- 26 April 1996 (V6.4) -- New EUVE Software and Reference Data Releases
- 29 March 1996 (V6.3) -- IAU Circular Regarding EUVE J2115-58.6
- 29 February 1996 (V6.2) -- Hot Spots in the SW Spectrometer
- 31 January 1996 (V6.1) -- Accepted Cycle 4 Proposals and Targets

---

1995 Issues:

- 22 December 1995 (V5.12) -- Two New Scientists Join CEA/EUVE Team; New GO Data Products Guide; 1:0 Phase 1 Transition Implemented in the ESOC
- 27 November 1995 (V5.11) -- Cycle 4 GO Proposal Summary; New IRAF/EUV and EGODATA Releases; EUVE Enters Safe-Hold Mode for the First Time; 1:0 Transition in the ESOC; EUVE Represented at Telemetering Conference
- 24 October 1995 (V5.10) -- TIF Reset Caught by AI Software; ESOC Procedures Augmented Using FrameMaker 5; Educational Outreach: Innovative CEA Information Server
- 25 September 1995 (V5.9) -- NRA Appendix E: Update on Observations; New On-Line Search Tools for Proposal Database; Spiral Dithering Test Resultsl; Cycle 3 Observation Scheduling Status Report
- 25 August 1995 (V5.8) -- VW Hyi Caught In Outburst As TOO; EUVE Optical Identification Discovery Announced in IAUC; CEA Teams with ARC on BU's TERRIERS Mission
- 19 July 1995 (V5.7) -- Release of Cycle 4 NRA; Educational Outreach Via SOL/SII, CEA Test-Bed Awarded CALSPACE Grant
- 16 June 1995 (V5.6) -- User's Committee Meeting at GSFC; Test of New Dithering Operatins; Scanner C Anode Blanking Enabled
- 17 May 1995 (V5.5) -- Innovations in Electronic Documentation; EUVE NRA for Cycle 4; Accepted Public RAP Proposals
- 18 Apr 1995 (V5.4) -- Release of egocs1.5.1; GI Program; Public RAP Proposals
- 17 Mar 1995 (V5.3) -- EUVE Papers for the IAU; Payload Health Status Report
- 01 Mar 1995 (V5.2b; NEWSFLASH) -- New Standard Data Collection Mode for EUVE
- 16 Feb 1995 (V5.2) -- EUVE Science Archive: 1994 in Review
- 20 Jan 1995 (V5.1) -- Approved Cycle 3 GO Programs; Failure of On-Board Tape Recorder Unit; EUVE Public RAP

1994 Issues:

- 22 Dec 1994 (V4.12) -- NASA Announces EUVE Extended Mission; EUVE Science at 185th AAS Meeting
- 16 Nov 1994 (V4.11) -- Update on EUVE Test-Bed Activities; EUVE Science Archive Guest Investigator (GI) Program
- 18 Oct 1994 (V4.10) -- NASA Administrator Dr. Dan Goldin Comments on EUVE; Education Outreach at CEA
- 14 Sep 1994 (V4.9) -- Public Release of the EUVE Sky-Survey Data
- 29 Aug 1994 (V4.8b; NEWSFLASH) -- Public Release of EUVE Sky Survey Data
- 10 Aug 1994 (V4.8) -- Early Results of the SL-9/Jupiter Impact Observations
- 13 Jul 1994 (V4.7) -- The EUVE Comet Impact Event: Cosmic Collisions
- 14 Jun 1994 (V4.6) -- EUVE User's Committee Extended Mission Proposal Presented at AAS; NASA's EUVE Observatory Researchers Share a Ride with Educators on the Information Superhighway
- 15 May 1994 (V4.5) -- NASA Astronaut Visits Bay Area; CD-ROM Volume 2, Number 2 for AAS
- 12 Apr 1994 (V4.4) -- The Beta Cen Mystery: Evidence for Recent Degradation of the Al/Ti/C Filter of Scanner A; First Hardware Failure on EUVE
- 25 Mar 1994 (V4.3a; NEWSFLASH) -- Initial Public Release of Guest Observer Data
- 09 Mar 1994 (V4.3) -- "Space News" Highlights EUVE Innovation in Science Operations

- 09 Feb 1994 (V4.2) -- IAU Colloquium Announcement: Astrophysics in the Extreme Ultraviolet; Right-Angle-Program Results at AAS
- 06 Jan 1994 (V4.1) -- EUVE CD-ROM V2.1 (A/B/C) to be Distributed; EUVE Innovation in Science Operations at CEA
- 05 Jan 1994 (V4.0a; NEWSFLASH) -- EUVE Strategy Session at AAS

1993 Issues:

- 06 Dec 1993 (V3.16) -- EUVE User's Committee Members; Spectrometer Dithering Test Results

Analysis of Individual Copernicus Scans of a Star

One the useful aspects of the Copernicus archive is that it can be used in searches for spectral variability of bright stars. Using gamma Cas as an example, let's say we want to check the results of <Slettebak and Snow (1978)> who reported the amazing development of emission in the UV resonance lines of Si IV and Mg II in just a few minutes. The feature was not present in the first spectral line Copernicus scanned, yet it was found to develop over the time it took the scan to reach the second (bluer) line in each doublet. Do we believe this? To check out this claim, we can access and compare individual Copernicus scans from the original study.

This can be done in a variety ways, either interactively on Copernicus Web pages, or using the IDL-based FITS readers ***mrdfits*** or ***ifitsrd*** (IRAF/STSDAS tasks do not yet read most Copernicus FITS files because these files generally contain variable array lengths. The IDL-based routine fxbread also works, but only on one file row (scan) per read. It is impractical to use it for reading many rows). It is usually convenient to determine first the scan numbers needed, e.g. by inputting the observing times into the Copernicus search page.

One should recall that Copernicus scans are stored in 5- or 6-row groups. This is because Copernicus observations were made with simultaneous U1 (U2, U3) and V1 (V2, V3) tubes. U3 and/or V3 were used to monitor particle backgrounds empirically. An alternate tube (e.g. U2 for U1, V2 for V1, or vice versa) was employed to shield the tube used for data collection from scattered light. Data for each of these tubes was recorded as a separate binary row (scan). Additionally, the ***tback*** field in each data scan is a modeled radiation background spectrum. This background can be subtracted from the ***tcounts*** array to produce a "net" spectrum.

Step 1: get object number and the scan numbers

The first step is to determine the object number of interest. A single FITS file for the object contains all the observations done by Copernicus. This file contains a 3-digit number corresponding to the object name for the mission. (This number is given by the ***star_num*** field.) To do this, go to the <complete target list> page. For gamma Cas, one finds the filename c084.pep, so the object number is 084.

Next one should determine the range of scan numbers. This can be best learned from the search Web page under "Co-added Scans" by putting in the starname, wavelength limits, and rage of observation dates. For our present query, enter "gamma Cas," "1380," "1415," and "27 Jan 1977 .. 29 Jan 1977), respectively, and run the search. One record is returned with the scan range 1974--2273. We may now download the software and work on it with our favorite IDL-based FITS reader.

Step 2: get the times

The REC_* keywords indicate only the time for a reference position in that Copernicus orbit during which observations were made, not the exact observation time (the difference between these times may be up to one orbital period of about 96 minutes). A conveninent way of getting the correct time of observation is to download the program ***coptime*** from the ftp area) (<ftp://archive.stsci.edu/pub/copernicus>) and use it for the scan(s) of interest to determine these times. This is shown for scans 1974-2273 as follows:

```
i  = indgen(300) +1974
coptime,'c084.pep',i
```

The output provides a listing of start and end times which are accurate to about 1s.

Step 3: read the file in your IDL session

Here are three examples of reading in scans 1974-2273 in ***mrdfits*** or ***ifitsrd***. Of the two routines, mrdfits reads in multiple file rows much faster, but ***ifitsrd*** permits an alternative to IDL structures and working with selected data fields. (For a primer on IDL structures, click <here.>)

Example 1, with mrdfits (structure only):

```
p  = mrdfits('c084.pep',1,h,range=[1973,2272])
```

(Note the 0-based indexing.)

Example 2, with ifitsrd (structure option)

```
i  = indgen(300) + 1974
ifitsrd,'c084.pep',i,h,e,p,/struc,/sil,/nvla
```

The array ***i*** contains the indices corresponding to the 300 scans of potential interest. The array ***h*** contains keywords unique to the object gamma Cas and is the header of the primary array record (which contains only this header, no data). The parameter ***e*** is the keyword header for each of the 40 data fields and includes the field name for each. The parameter ***p*** is the data structure containing the observations. The IDL keyword ***/struc*** specifies the data are to be packed into an IDL structure, while ***/sil*** suppresses a summary of the data contents to the screen. In this case, ***/nvla*** is critical for Copernicus files because it suppresses an optional keyword array which would attempt to report the number of elements in the variable length arrays. For Copernicus data this value, the number of wavelength points scanned, often varies from observation to observation. If ***/nvla*** is not specified, the run of ***ifitsrd*** will abort if the number of array elements in successive scans differs from the first scan read.

An alternative way of examining the data structure contents is to type:

```
help,/struct,a
```

By either printing out of the keywords in the string array ***e*** or by this "help" command one obtains the field-name convention needed to work with data fields.

Example 3, with ifitsrd (selected fields option):

Let's suppose we want work with the following fields: **rec_num, tube_name, nnn** (array length)**, yr_obs, day_obs, hr_obs, min_obs, tlambda** (wavelength array)**, tcounts (raw counts), tback (background)**. These are, respectively field numbers 3, 14, 15, 16, 17, 18, 19, 36, 37, 39), which we will designate as variables with the letter f. In the call to ***ifitsrd***, we use the keyword **efld** to list these field numbers corresponding to the extracted data fields, as follows:

```
i   = indgen(300) + 1974
ifitsrd,'c084.pep',h,ex,i,f3,f14,f16,f17,f18,f19,f36,f37,f38, $
  efld=[3,14,16,17,18,19,36,37,38],/sil
```

Step 4: Work with the data

At this point it's a good idea to check on the wavelength direction of the scan, e.g. by printing out the first and last wavelength element. These elements are numbered in the sense they were observed, with the first element (either shortest or longest wavelength) being the one first recorded in time.

From coptime and the Slettebak and Snow paper, we find that the observations of interest are scans 2144 (Si IV doublet) and 2145 (Mg II) doublet. These are monitored by the U2 and V2 tubes, respectively. We may compare these, for example, to the immediately preceding observations, 2139 and 2140, by printing or plotting them out. Note here that all arrays are padded to 176 elements (except for arrays already containing 176 scanned elements). Thus, generally we must first determine the number of actual (nonzero) data points; for these two pairs of observations these array lengths are 148, 176, respectively. Finally, we plot out the arrays of interest. For example:

```
plot,a(170).tlambda(0:147),a(170).tcounts(0:147) - a(170).tback(0:147)
oplot,a(165).tlambda(0:147),a(165).tcounts(0:147) - a(165).tback(0:147), linesty=2
```

and so forth.

How to Read Copernicus Files

This page provides information on reading the Copernicus data sets using FITS readers written in various languages. As mentioned elsewhere, all the Copernicus data sets use the FITS binary table extension format which was approved by the IAU in 1994. The raw data sets however use the variable length array facility which, although included in the original binary table proposal, was not part of the officially approved format. Users may have more trouble therefore reading the raw files than the coadded scans or spectral atlas files, although there are many publicly-available FITS readers that can read all 3 formats.

FTOOLS:

One of the best supported, and most extensive, FITS readers is the **FTOOLS** and FITSIO software library written in C and FORTRAN by Bill Pence from **HEASARC**. These programs should be able to read all the various Copernicus data sets. The suite of programs can be built as either a stand-alone package or as an IRAF subpackage. The **first example** shows how to convert a quick-look co-added spectrum to an ASCII table. The **second example** hows how to create an ASCII table containing a single scan from a raw data (.pep) file. The **third example** shows how to access and manipulate individual Copernicus scans in a time series of a target pep file (i.e. constituent scans of the co-added data).

IDL FITS Readers:

There are a number of FITS readers that are written using the Interactive Data Language **(IDL)** A number of the FITS readers are included in IDL libraries that are available for free via the WEB and run on several different platforms. (Note however that IDL must be purchased for the local computer). One such library is the **IUEDAC** software package, originally written for analyzing data from the International Ultraviolet Explorer (IUE) satellite project. The **IUEDAC examples** show how to use the program **IFITSRD** to read the raw, coadded scan, and spectral atlas files, and plot counts versus wavelength. More information on **IFITSRD** can be found in the prolog of the program.

Another widely used IDL library is the **IDL Astronomy User's Library**. This library contains astronomy-related programs donated by several projects and includes several IDL FITS Readers. Three of the FITS readers are described in the **Astronomy Library examples**. (note that the Readfits(), Fits_*, and FTAB_* routines can not read the variable length arrays used in the raw data sets, but CAN read the coadded scan and spectral atlas FITS files). Additional documentation on all the listed IDL programs can be found in the procedure prologs.

Stray Light in PEP

D. G. York

December 8, 1972

Recently, a test was done on Lambda Ori to determine the cause of residual light at the bottom of saturated absorption lines. The basic procedure was to hold U1 fixed at the bottom of four lines: 1026 Å, 1077 Å, 1216 Å, and 1302 Å, while moving Carriage two. Far from the suspected stray light source (50 Å longward of the U1 slit), observations were made by moving U2 20 Å at a step, then doing a standard routine on U1 with U2 motionless. At Ly Alpha and Ly Beta, the standard routine did not take U1 out of the bottom of the line. For the 1302 line the standard routine included a point in the continuum shortward of the line wings. For the 1077 line, a point in the shortward wing was included.

These low resolution results are shown in Figures 1, 2, 3, and 4. In Figure 2, the regions where the slit and stray light hole are separately or simultaneously occulted are labeled. In Figure 3, the various background components are labeled as 1) particles, 2) stray light through the hole about 50 Å longward of the slit, and 3) scattered light. This last designation comes chiefly from the fact that a component of background remains after the dipping mirror occults the stray light hole and before the slit on U1 is occulted by the mirror, but the component disappears when the slit is occulted. This component may be due to grating scatter or to some other very localized scatter.

High resolution scans of the stray light occultation are shown in Figures 5 and 6 (with U1 at 1216 Å and 1026 Å, respectively). Counts on U1 are shown as a function of the U2 slit wavelength. The discontinuity after dump 1397 in Figure 5 may be partially explained by a high particle count on U1 (U3 showed a background level three times higher than normal). The discontinuity at dump 1415 in Figure 6 is not so easily explained.

The present position of the dipping mirror relative to the U2 slit is shown by occulting the U1 slit positioned at continuum points near Ly Alpha and Ly Beta in Figures 7 and 8.

Based on the various background components observed, the following scheme was derived for computing background corrections where saturated lines are not available, i.e., particularly in the case of molecular lines and unreddened stars.

Lambda=wavelength being observed on U1
$S_{2,avg}$(Lambda + 55)=average continuum level on U2 measured from a point 55 Å greater than Lambda and averaged over ± 17Å.
$S_{2,avg}$(Lambda ± 10)=average U2 continuum centered at Lambda averaged over ± 10Å.
a=a correction to derive $S_{1,avg}$(Lambda ± 10), comparable to $S_{2,avg}$(Lambda ± 10). a is plotted in Figure 9.
$S_{1,avg}$(Lambda ± 10)=$S_{2,avg}$(Lambda ± 10)/a

The stray light on U1 at Lambda in counts/14 sec on U1 is

S_t = 0.1 x C_1 x $S_{2,avg}$(Lambda + 55) where C_1 is defined below.

The scattered light is

S_c = 0.08 [$S_{1,avg}$(Lambda ± 10) - 0.1 x $S_{2,avg}$(Lambda + 55)]

To determine the state of occultation, compute the quantity Delta E = E_{U2}-E_{U1}, the wavelength difference of U2 and U1, in Å. Define the additional correction for occulted stray light as C1.

If Delta E < -170, C1 = 1.0.

If -170 < Delta E < -100, C1 ~ 0.75 - 1.0, a poorly defined effect which is not understood. This condition does not occur often.

If Delta E > 0, compute

z = Delta E - 0.143 Lambda_{U1} + 35
If $|z|$ <= 17, C1 =(17 + z)/35.
If $|z|$ > 17, C1 = 1.

The equation for z is derived using a measured wavelength dependence in the separation of U1 and U2 when half the stray light is occulted.

The above formalism applied to Lambda Ori observations of saturated lines gives predicted values within about 10% of those observed for residual signal at the center of saturated lines. For Tau Sco (B0 V), Gamma Ara (B1 Ib) and Delta Per (B5 III), the answers given by the formalism must be increased by 30%. With this addition, 10 to 15% accuracy is achieved. The background particle counts may vary from 15/14 sec to 80/14 sec, and the counts at the line centers for all but the shortest lines in Tau Sco are less than 2000/14 sec. These have not been taken into account and probably account for a part of the error.

The above statements of accuracy do not apply to the regions Delta E <= |17|, or in fact Delta E <= |25|. There is some evidence that the apparent size of the hole changes as U1 moves to shorter wavelength, as is shown by the comparison of stray light occultations in Figures 2 and 4.

The present results are probably acceptable for U1 wavelengths 1100 Å < Lambda < 1400 Å for all z. At shorter wavelengths they are acceptable for $|z|$ > 25, but for smaller $|z|$, they must be applied with caution. In particular, the features near 1036 Å are often affected by partial occultation of the stray light hole. L. Spitzer has obtained good predictions of background for these lines using the following corrections.

Compute EL - E2 where E2 = the Carriage 2 encoder reading for a particular observation on U1 and EL = the corresponding longward occultation point of the V1 slit. These numbers are available in the "LS" printouts.

Compute C_2 = 43000 - (EL - E2) = distance of C2 mirror from edge of U1 beam, in encoder bits.

If C_2 < 15 K, C1 = 0.

If C_2 > 30 K, C1 = 1.

If 15 K < C_2 < 30 K, C1 = (C2 - 15 K)/15 K.

Stray Light in PEP, II

D. G. York, December 15, 1972

Pursuant to the derivation of extinction curves using U2 data, a formalism has been developed for deriving the stray light which contaminates the U2 spectrum.

The degraded spectra (5 Å and 10 Å resolution) of Zeta Oph (O9.5 V, E_{B-V} = .33) and Alpha Cam (O9.5 Ia, E_{B-V} = .32) are shown in Figures 1 and 2, respectively. Also shown is the stray light shifted 18 Å longward to show its approximate fit to the 5 Å resolution spectrum, discussed below.

The best way to derive the correct stray light values is from the saturated atomic and molecular hydrogen lines in reddened stars. As may be seen in Figures 1 and 2, the stray light has considerable structure, even over 3 Å (see the region near 1026 Å). Since this phenomenon is noted in virtually all reddened stars, it is plausible to assume that the structure is due to the molecular hydrogen lines, at least in part. The presence of this structure requires a narrow bandpass for the stray light aperture since our targets do not show structure on scales greater than 15 to 20 Å, and these large amounts only occur in supergiants showing mass loss.

Test results obtained at Goddard before launch are illustrated in Figure 3. The U2 cathode was incorrectly positioned, causing Lyman Alpha to appear when the U2 tube was 17 Å shortward of the true Lyman Alpha position. (The identification of the feature in Figure 3 is solid, based on the relative strength of another H_2 line at near 1218 Å, observed at the same time.) Presumably, dispersed light was getting in behind the longward edge of the U2 slit jaw, which is about 17 Å from the U2 slit, and hitting the U2 cathode which was not seated properly. The cathode was moved toward the slit jaws and the main light path was removed (dashed line in Fig. 3). However, some residual stray light does appear. Time did not allow for further investigation. The dashed line in Fig. 3 suggests that the present stray light path yields a resolution greater than 3 Å.

By trial and error, it has been found that the stray light may be represented as 60% (±10-15%) of the true stellar spectrum, expressed in U2 counts per 14 seconds, 20 Å longward of the point in question and integrated over 5 Å.

S_t(Lambda) = $S_{*,avg}$(Lambda + 20) x 0.6

where

S_t(Lambda) is the stray light at Lambda

S_*(Lambda + 20) is the U2 signal *averaged* over a 5Å band centered 20 Å longward of Lambda.

Since $S_{0,avg}$(Lambda), the observed average counts at Lambda in a 5 Å band is

$S_{0,avg}$(Lambda)=S_t(Lambda) + $S_{*,avg}$(Lambda) = S_*(Lambda + 20) x 0.6 + S_*(Lambda)
$S_{*,avg}$(Lambda)=$S_{0,avg}$(Lambda) - S_t(Lambda)
=$S_{0,avg}$(Lambda) - $S_{*,avg}$(Lambda + 20) x 0.6
=$S_{0,avg}$(Lambda) - $S_{0,avg}$(Lambda + 20) x 0.6 + $(0.6)^2 S_{*,avg}$(Lambda + 40)

Repeated substitution using the formula

S_*(Lambda + 20*i*) = S_0(Lambda + 20*i*) - S_*[Lambda + (*i*+1)20] x 0.6

leads to the formula

$S_{*,avg}$(Lambda) = $S_{0,avg}$(Lambda) - Sum$_{i=0 \text{ to } n} 0.6^{(i+1)} S_0$[Lambda + 20 x (*i*+1)]

or

S_t(Lambda) = Sum$_{i=0 \text{ to } n}$ $(-1)^i 0.6^{(i+1)} S_0$[Lambda + 20 x (*i*+1)]   (1)

For spectral distributions in reddened or unreddened OB stars, n = 5 is sufficient for convergence to occur.

For specific points in the U2 spectrum, equation (1) may be applied to derive the stray light to be subtracted from the observed U2 signal. If an entire spectrum is to be corrected, it is easiest to apply equation (1) at some long wavelength point and work one's way shortward, using the formula

S_t(Lambda) = S_*(Lambda + 20) x 0.6

where S_*(Lambda + 20) is computed at each point,

S_*(Lambda + 20) = S_0(Lambda + 20) - S_t(Lambda + 20).

Table 1 shows the results of applying these results to both reddened and unreddened stars at wavelengths greater than 1000 Å. The structure in the stray light is duplicated and agreement of observed and computed values is generally within 20%. The particle counts of 14 to 80 per 14 sec have not been subtracted from the observed stray light values quoted in Table 1.

This formation does not provide an *exact* fit to the stray light observed, and one wonders, additionally, what the other modes of stray or scattered light might be. We have assumed herein that the U1 stray light path (light from 50 Å longward) does not exist an U2, which may not be true. Separation of these various components remains a topic for later investigation. Addition of other components may force one to use a narrower bandpass for integrating the light 20 Å from the slit.

Table 1

Computed and Calculated Stray Light Levels On U2
U2 counts per 14 seconds are given

	Alpha Cam		Zeta Oph		Lambda Sco		Tau Sco	
	Obs	Calc	Obs	Calc	Obs	Calc	Obs	Calc

Scattered Light in U1

W. Cochran

March 2, 1973

Saturated lines of several stars were examined to determine the amount of scattered light in the U1 spectra. Lines were selected in which the stray light was fully occulted. It was then assumed that any residual light in the bottom of saturated lines was purely a result of scattered light.

The counting rates in the bottoms of heavily saturated lines were measured. Following York*, the continuum level, averaged over ±10 Å, was measured on U2 and then divided by the quantity *a* (see Fig. 9 from York) to correct for the difference in counting rate between U1 and U2; i.e.,

$$S_{1,avg}(\text{Lambda} \pm 10) = S_{2,avg}(\text{Lambda} \pm 10)/a\ . \qquad (1)$$

The ratio of the counting rate at the bottom of the line to the average continuum level, $S_{1,avg}$(Lambda ± 10), plotted as a function of wavelength, is shown in Figure 1. The data shows a linear relationship, which can be described by

$$N_{min}/S_{1,avg}(\text{Lambda} \pm 10) = 0.047 + 0.000185(\text{Lambda} - 1000)\ , \qquad (2)$$

where Lambda is measured in angstrom units.

The ratio of the counting rate at the line bottom to the local continuum as measured on each U1 scan was also examined, but these data showed considerable scatter. Thus the above formula gives the best available representative for the scattered light in the U1 spectra. The average deviation of the plotted points from the mean line is 0.0059 of the computed U1 continuum.

MEMORANDUM TO: Users of *Copernicus* data
FROM: D. York and A. Miller
SUBJECT: Background in *Copernicus* Data Tubes

I. INTRODUCTION

For some period of time we have had underway an extensive programming and data reduction effort with the goal of producing background predictions for use in correcting *Copernicus* data. In this memo we describe the present state of this work.

This report discusses the data reduction procedures (§ II); the results, including typical background count behavior for the six tubes (§ III); and the possible sources of the background counts in light of the characteristics of the individual tubes (§ IV).

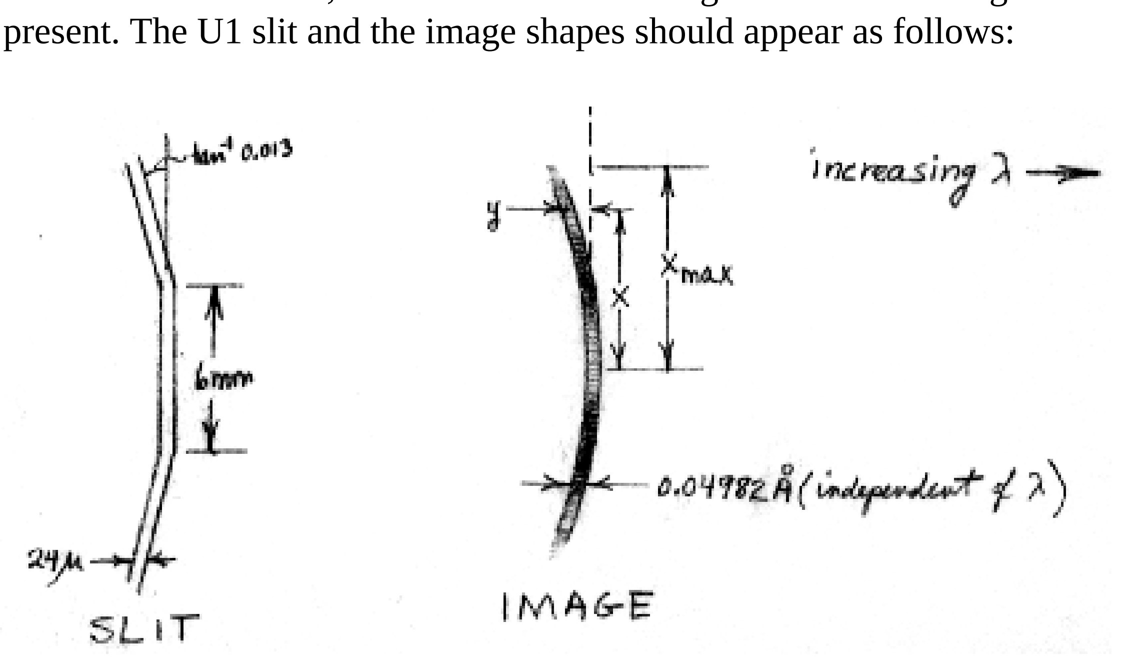
SUBJECT:Computations of the U1 Instrumental Profile

---

a) Star Image

The shape of the instrumental profile for U1 has been computed under the assumption that the spectrometer is exactly in focus, the grating is perfect, the starlight illumination is uniform across the entrance slit, and no aberrations of higher order than astigmatism and coma are present. The U1 slit and the image shapes should appear as follows:



Note that the brightness of the image varies along its length; this is caused by uneven illumination of the grating. Occultation by the spectrometer and secondary spider casts a shadow on the grating which produces an intensity distribution

$\|x/x_{max}\|$	0.0	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9	1.0
$I(x)$	0.00	0.30	0.29	0.28	0.88	0.83	0.76	0.67	0.55	0.40	0.10

We assume the grating efficiency and telescope mirror efficiencies are uniform over their surfaces. The above numbers represent the illumination pattern along successively higher strips, from center to edge, which are perpendicular to the rulings. (We ignore a slight asymmetry in the pattern, which makes $I(x)$ slightly different from $I(-x)$ for $|x| \sim 0.4$.)

If R is the radius of curvature of the grating (and the diameter of the Rowland circle; this value is 998.8 mm), the height L of the illumination on the grating is $R(\cos i)/20$ for an $f/20$ beam with an angle of incidence i. The astigmatic image height is given by

$$2x_{max} = L \text{ Gamma}$$

where Gamma = $\sin^2 r + \sin i \tan i \cos r$ (r is the angle of diffraction). The curvature of this image follows the relation

$$y = -\text{Psi } x^2/2R$$

where

$$\text{Psi} = [\sin i \tan^2 i - \sin r + \{\tan r(1 - \text{Gamma})^2\}/\cos r] \text{ Gamma}^{-2}$$

For most wavelengths along the spectrum the segmented slit compensates for the curve. To ascertain the small smearing which results from the lack of a perfect match, we may define an offset

$$y'(x) = y(x) \text{ for } |x| <= 3.0 \text{ mm}$$

and

$$y'(x) = y(x) - 0.013(|x| - 3.0 \text{ mm}) \text{ for } |x| > 3.0 \text{ mm}$$

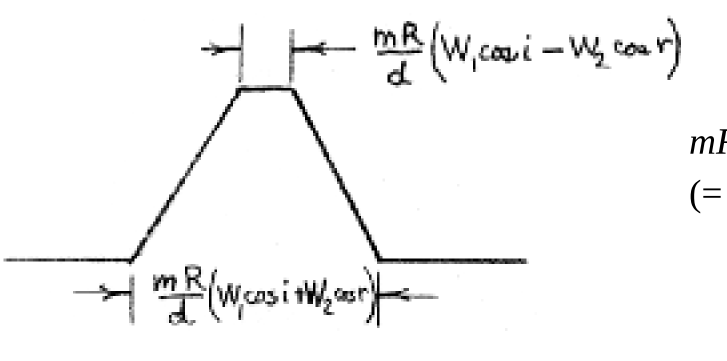
If the entrance and exit slits had infinitesimal widths, we would expect an instrumental profile whose shape follows the function

$$P(y') = \text{Sum } (dy'/dx)^{-1} I(x)$$

where the sum includes all points along the line from 0 to x_{max} where the function crosses y'. The conversion from y' to Delta Lambda is given by

Delta Lambda = $mR/d \cos r\, y' = 2.0858 \times 10^3 \cos r\, y'$ for y' in mm and Delta Lambda in mÅ

(m and d are the order and groove spacing, respectively). If one were to scan across any small piece of the curved image with the exit slit, one would expect to see the convolution of the two slits which results in a trapezoid,



$mR/d\, W_1 \cos i$ = 49.82 mÅ
(= $FWHM_1$ at all Lambda)

where W_1 and W_2 are the entrance and exit slit widths, respectively.

Although the face of the exit slit is always tangent to the Rowland circle, the effective width W_2 varies slightly with wavelength since the light strikes the jaws at the diffraction angle r from the normal, and the jaws are not perfectly thin. The projected widths as seen from the grating $W_2 \cos r$ has been measured by Perkin-Elmer and a functional fit to these data has been made by J. B. Rogerson.

A convolution of P(Delta Lambda) with the above shown trapezoid gives us the net instrumental profile, which includes the slit widths and the small lack of registration of exit slit shape with the image curvature. Some additional smearing should be caused by spherical aberration, giving an image diameter

$$A = L^3/(8R^2)\, (\sin i \tan i + \sin r \tan r) \cos r$$

which may be multiplied by $2.0858 \times 10^3 \cos r$ to give the value in mÅ. The above figure, however, is appropriate at the paraxial focus. The aberration may be substantially reduced (by about a factor of four, I am told), by viewing the line at the circle of least confusion, instead of the paraxial focus.

b) Diffuse Sources

If the entrance slit is illuminated uniformly over its entire length l (3.0 mm), the diffracted image is smeared vertically over a length $l \sec i \cos r$. However, for any point source off the grating centerline the displacement of the focused image is not exactly vertical, but rather occurs along an arc concave toward longer wavelengths (i.e. opposite to the curvature of the image) whose radius of curvature

$$r_e = R/\text{Phi}$$

where Phi = $(\sin i + \sin r)/\cos^2 r$. For the *Copernicus* spectrometer actual values of r_e are several times larger than the radius of curvature of the image R/Psi defined earlier. The net instrumental profile for a diffuse source can be evaluated by adding together the profiles for many single point sources arranged along the entrance slit.

c) Presentation of Results

The graphs show for 950 <= Lambda <= 1400 Å, in steps of 50 Å, three computed profiles:

1. Simple trapezoids from the slit convolutions.
2. Profile for a star imaged on the slit center,
3. Profile for a diffuse source illuminating the whole slit.

Because of the uncertainty of the actual focus condition of the spectrograph, no attempt was made to include the smearing from spherical aberration (we also have no firm way of knowing the effect of other sources of image blur or lack of registration). In addition to a slight broadening over (1), the mean Delta Lambda of profiles (2) and (3) are displaced (usually) toward shorter wavelengths. When the profiles were plotted, they were shifted so that their "centers of gravity" were coincident, to facilitate the comparison of shapes. The amount of these shifts for (2) and (3) in mÅ are shown as CG2 and CG3, respectively. Positive values for these quantities mean the centroid of the complete profile falls at shorter wavelengths than the simple trapezoid (on axis image). Also shown on the graphs are computed values for i, r, Gamma , Psi , Phi, and A. The values of A shows us the basic magnitude of the spherical aberration and its behavior for changing wavelengths.

It is of interest to compare the computed curves with actual observations in orbit. Two sources of information are available at present. First, W. Morton and L. Spitzer have measured stacked profiles of H_2 lines which are presumed to be quite narrow. They find a good fit for the region 1025 <~ Lambda <~ 1100 Å is a gaussian profile with a FWHM = 51 mÅ. This relation is plotted as a series of dots on the 1050 Å graph, and it is evident that no really significant source of additional smearing is at work in the spectrograph, except possibly in the wings beyond | Delta Lambda | = 40 mÅ. The other main source of observational material is the stack of geocoronal Lyman Alpha emission scans. Here, however, the emission profile is not so much smaller than the instrumental profile that we may ignore its effect in producing a slightly broader profile. In connection with research on the cometary Lyman Alpha observations, J. L. Bertaux has examined the geocoronal data and has also theoretically estimated the true Lyman Alpha profile shape. The observations give an approximately gaussian profile with FWHM = 67 mÅ while the emission profile is expected to be 38 mÅ wide. We therefore would expect to find the response of our instrument to a diffuse source of Lyman Alpha of infinitesimal width in Delta Lambda to be roughly a gaussian with FWHM = $(67^2-38^2)^{1/2}$ = 55 mÅ. The computed curve at 1200 Å has FWHM = 60 mÅ; perhaps the geocoronal emission width was overestimated by Bertaux or else the difference may be attributable to the fact that the instrumental profile is not really a pure gaussian distribution.

FROM: W. Budich, R. Bohlin and J. Drake
SUBJECT: Corrections to the U2 Wavelength Scale Between 1026 and 1110Å.

To determine the correction to the U2 wavelengths several interstellar lines of molecular hydrogen between 1040Å and 1113Å were investigated in the spectra of 17 stars. The position of the lines were measured in the frame of the most prominent interstellar feature in the visible. Deviations of the H_2 velocities from the visible value and any other random shifts were assumed to average to zero for the 17 stars as a group. The average shifts were plotted and approximated by the two straight lines shown in Figure 1. The fit was drawn through the (1026, 0.18Å) point found earlier by Bohlin during a study of Lyman Beta. In the course of the Lyman Alpha survey work, no evidence for a systematic shift at 1216Å was found. The U2 wavelength scale at La is certainly well within the quoted error of ±0.05Å. The equations for the two straight lines are

Delta Lambda = -0.002425Lambda + 2.668 for Lambda < 1070Å

and

Delta Lambda = -0.00066Lambda + 0.779 for Lambda > 1070Å.

In the implementation of the shifts in the GSFC reduction, the equations are applied for all Lambda < 1180Å, where the correction is zero.

Table 1 shows the residuals between the actual and measured wavelengths after applying the above correction. The averages shown for each star are the combination of the actual difference between the H_2 and visual cloud velocities, random errors in the procedure, and temperature or other instrumentally caused shifts. The average residual shifts are applied to the data before attempting to derive H_2 column densities.

Princeton University Observatory
SUBJECT: Possibility of spurious emission line detection

Some of you have been trying to detect weak emission lines using U1 or U2. This is to make you aware of the fact that it is possible to produce spurious emission lines, at the level of 5 cts/14 sec at arbitrary wavelengths. For a given program, the features are likely to occur at identical wavelengths for repeated scans, so that in stacked data, the features will appear to be statistically significant.

The cause of the spurious features is that U1, when slewed, will produce pickup in the U2 count registers (or associated electronics), and vice versa. We generally do not try to obtain U2 data or U1 data while either carriage is slewing. However, tube U1, when retracing, slews 2 steps further than the start position of a scan, and takes two antibacklash steps. The main retrace slew (-17 steps), occurs during the 2 second period used to store data, and hence any pickup produced never occurs in the count registers. However, the two antibacklash steps (2 sequential +1 steps) occur during a valid integration period, and thus will be stored in memory. In the process of reducing data, this quarter minute of data is discarded for U1 and never appears in any plots or on disc records of the U1 data. However, if U2 is moving, this frame is regarded as valid data for that tube and it is plotted and stored on disc. Thus, if U1 and U2 standard routines are started simultaneously, the first point of the U2 scan will include some pickup from U1. If a U2 standard routine is started, and a U1 standard routine is started 1 minute later, the 5th U2 point will include pickup, etc. Each subsequent U1 retrace will lead to a corresponding blip on U2. The effect would go unnoticed except in the case where there is very low continuum signal, several scans have been stacked together, and U1 is always retracing when U2 reaches a particular wavelength, as for instance occurs when one line is being looked for on U1, another on U2, and U2 is reversed after a fixed number of U1 standard routines. In this case the blip will be reinforced on all negative U2 scans at certain wavelengths, and at a different set of wavelengths for positive U2 scans. The effect can be easily recognized by stacking all positive scans only, and then all negative scans separately.

I thank Bill McClintock (Johns Hopkins) for calling this problem to my attention. I urge you to check that this effect has not compromised any published data, and to take this subtle pitfall into account in any further data reduction with which you are involved. In my experience, in testing and in orbital operations, the amplitude of the pickup caused by carriage slews is variable, and therefore may be weaker or stronger than the 5 cts/14 sec quoted here.

SUBJECT: Sensitivity Loss in *Copernicus*

Summary. Comparison of *Copernicus* signals from a sealed photomultiplier tube (with a LiF window) with those from the open-face U1 photomultiplier shows that at least 80 percent of the large sensitivity loss observed at 1340 Å with U1 during the final few years of *Copernicus* operation must be attributed to degradation of the open-face tube, rather than to decrease in reflectance from the mirrors and grating.

In my memorandum of January 5, 1982, I summarized evidence that bombardment by atmospheric atoms produced the high voltage glitches and, to some extent, the sensitivity degradation experienced by *Copernicus*. The detailed mechanism of sensitivity degradation was not discussed.

Loss of sensitivity by far-UV open-face photoelectric detectors is potentially a very serious problem for the projected far-UV satellite, now designated as the FUSE program. Don York's request that I forward to Al Boggess any memoranda summarizing our *Copernicus* experience in this area has reawakened my interest in this problem.

Several years ago Walter Upson pointed out that the sensitivity loss of the closed U3 phototube through orbit 30,000 (March 1, 1978) was "significantly less than a factor two"; in contrast, the sensitivity of the U1 open-face photomultiplier, measured at 1340 Å, was about a factor two. As you know, the nominal wavelength of the U3 tube is about 1340 Å, and while the mirror directing light to this tube is covered with a metal disc (so that this tube can be used to measure the background produced by energetic particles), a weak additional signal is received by this tube when the telescope is pointed at a very bright star; the variation of this signal with stellar apparent magnitude and spectral type is consistent with the assumption that U3 is measuring stellar photons at about 1340 Å.

This effect pointed out by Walter is of great importance, since it suggests that the loss of sensitivity was not produced by the optical system --primary mirror, secondary mirror and concave grating --which feeds these two phototubes. Instead, the loss of sensitivity of U1 may be attributed in large part to degradation of this open-face phototube, presumably of the KBr coating on the photocathode; degradation of the BeCu dynodes in the multiplier section would not account for the increased sensitivity loss at the shorter UV wavelengths. Since the U3 photomultiplier is a conventional sealed unit, with a CsI photocathode and a LiF window, the presence of contamination vapours in the spectrometer would not be expected to degrade the performance of this tube, though other factors could produce degradation.

Since the U1 degradation by 1978 was not very large, this argument did not seem very decisive. To obtain more definitive data, I have now examined the U3 signal from the bright star Beta Cen as a function of time until orbit 41,000 (June 1980), and compared this with the normalized U1 sensitivity at 3,400 Å plotted in the Final OAO-C *Copernicus* Operations Report, 1982 (Fig. 2-1). The results are shown in the accompanying figure. Each U3 point represents the average 14-second count in a group of adjacent orbits (usually 2 to 5 in number), with 2 to 4 scans averaged in each orbit, and 16 individual counts averaged in each scan. The U1 points are based on smoothed representations of the observations.

Evidently the sensitivity at 1340 Å, near the end of the satellite's operational life at about orbit 44,000 (February 1981), amounted to about 15% of its initial value for U1, as compared to about 60% for U3, some four times as much. The data in the figure seem to show conclusively that degradation of the optical system cannot be responsible for most of the sensitivity loss observed with U1 at 1340 Å. Since the observed small degradation of U3 could be produced by increasing opacity of the LiF window on this tube, the sensitivity loss attributable to reduced reflectance of mirrors and grating cannot be determined, but at 1340 Å cannot exceed one fourth of the total degradation observed with U1.

At shorter wavelengths there is no firm evidence on the relative importance of mirror reflectance and photocathode sensitivity in the overall degradation noted. The degradation appears somewhat greater on U2 than on U1, suggesting that reflectance losses at the diagonal mirror in the U2 optical train are contributing significantly to the degradation. However, it is also possible that the difference between these two phototubes is a result of differences between the two photocathodes, possibly resulting from their different location and orientation in the spectrometer.

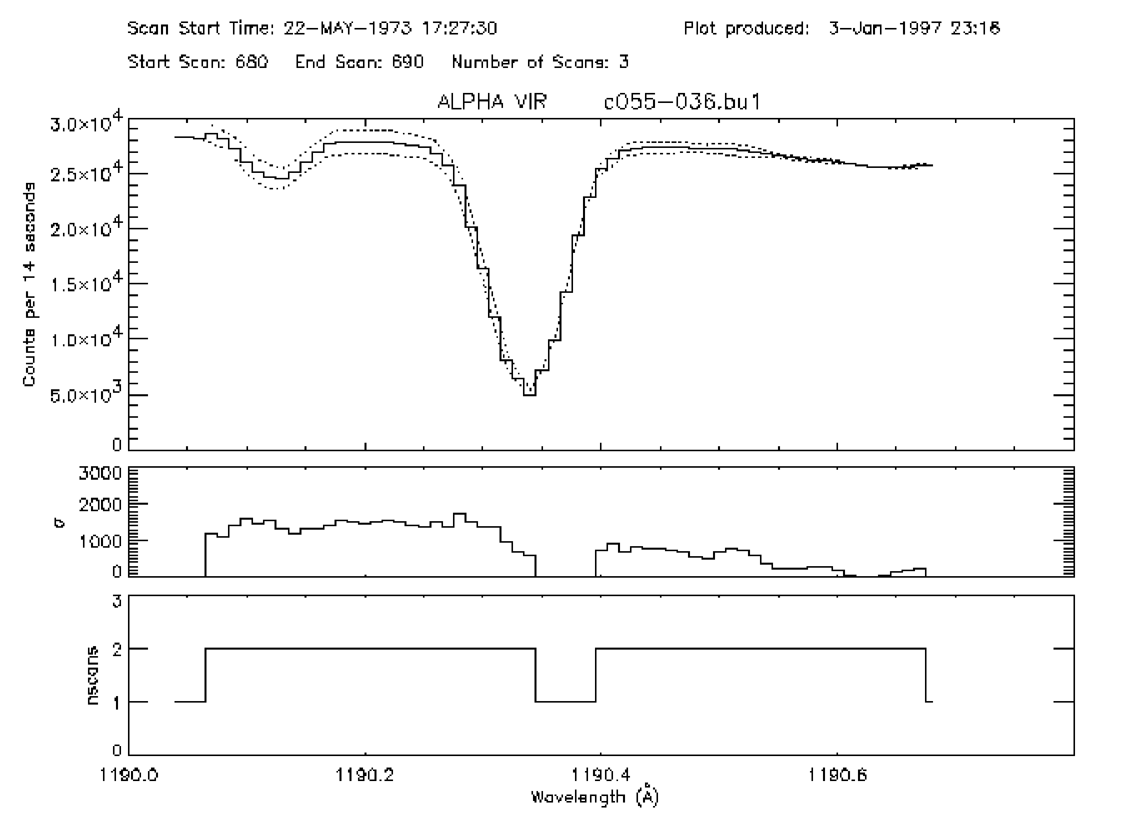
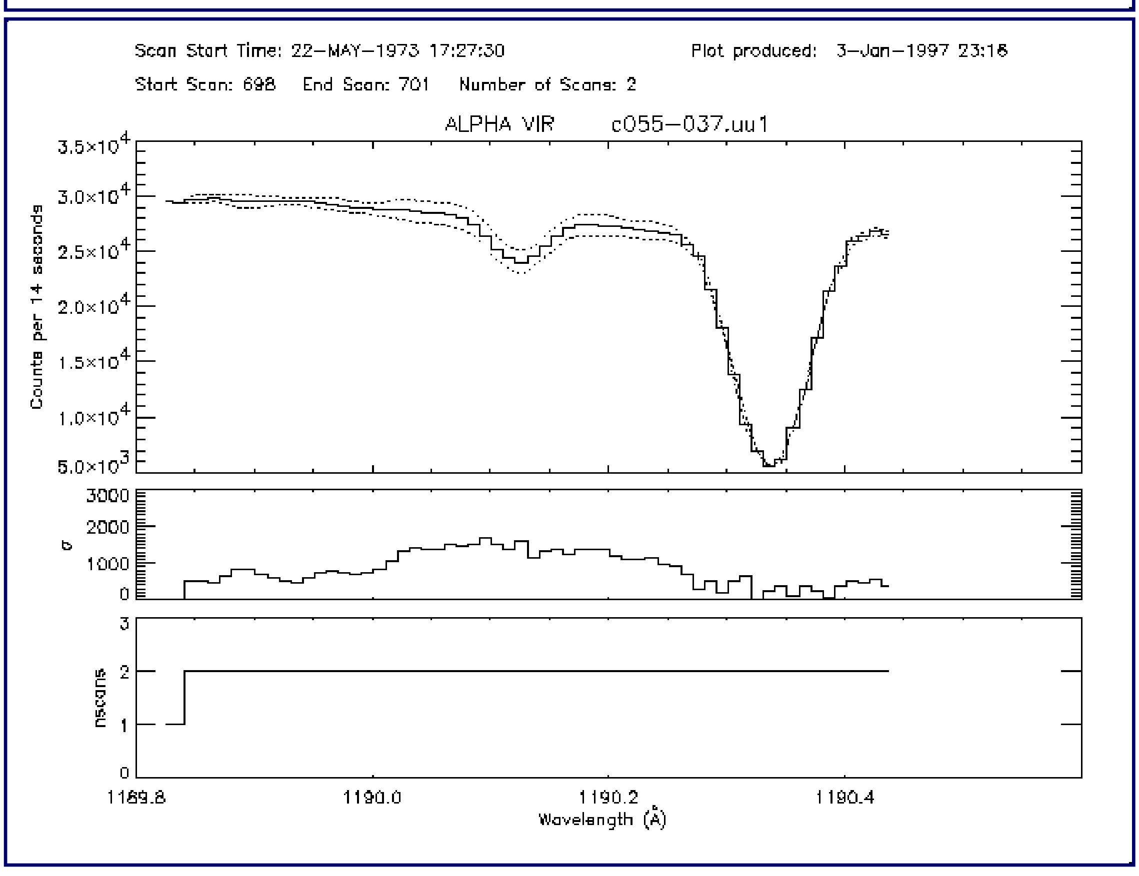
The Backgrounds - Particles, Stray Light, and Scattered Light

There are three sources of background counts for data taken with the *Copernicus* spectrometer - particles (cosmic rays), stray light, and scattered light. Each of these presents specific reduction issues which are briefly discussed below, users of the *Copernicus* archive are urged to consult the references mentioned below and other papers from the literature before using the data.

The particle background was routinely calculated for observations taken after the first eight months of operation as a function of spacecraft latitude and longitude at the time of observation. To allow for the correction to the extrapolated predictions of particle background flux, dark counts were measured about every four orbits. For the U1 and U2 tubes the counts due to particles was generally insignificant except when the spacecraft was in the South Atlantic Anomaly where observations were normally not taken (see also Rogerson *et al*. 1973 and the **Description of the Princeton Experiment** in Section 3 of the Guest Investigator's Guide). For many stars, the data from the *Copernicus* team at Princeton includes the background contributions due to charged particles for each scan. For data that does not include this information in the file a look-up table is consulted which gives the background count rate as a function of spacecraft position and time of observation. The particle background was removed during creation of the stacked scans.

Stray light reached the phototubes through out-gassing holes in the spectrograph. For observations taken using the U1 tube the stray light from the out-gassing holes was often blocked by positioning carriage-2 just longward of the U1 exit slit to cover the holes; however, not all data was taken with the out-gassing holes blocked. The Copernicus archive lists data as being either blocked or unblocked to denote whether carriage-2 was known to be in the correct position to block the vent holes. Some scans are marked as unblocked that actually were blocked, however the position of the U2/V2 tubes is not known so the scans are flagged as unblocked. For example, the following scans of the SIII and SiII 1190Å lines have the same background level (as judged by the level of the continuum and the depth of the core of the strong SiII line), but only the first set of scans have corresponding U2 scans to give the position of carriage-2:





Stray light was generally the dominant background source, so it is important not to mix blocked and unblocked data when stacking. An empirical correction for stray light for the U1 tube in any given (unblocked) scan can be derived in a manner similar to that used for scattered light below. The correction of U2 data for stray and scattered light is described by Bohlin (1975).

In addition to the particle and stray light backgrounds described above, there is a residual background of about 10 percent or more of the continuum for U1 observations using the U1 tube, this background is generally attributed to scattered light from the grating. In most cases the scattered light correction must be derived from residual counts in the bottom of saturated stellar or interstellar lines. The observing scheme usually used included the observation of strong interstellar lines (including the Lyman lines of HI, CII 1036 and 1334Å, CIII 977Å, NII 1084Å, OI 1302Å, and SiII 1260Å), the background was then empirically determined by assuming that some or all of these features were saturated, and thus should have no residual counts in the line cores (see Rogerson *et al*. 1973b; Morton 1975; Bohlin *et al*. 1983). In determining the background it is important to not mix blocked and unblocked scans as the background level varies widely between the two (although as mentioned above some scans were blocked but the necessary carriage-2 position information was not recorded, such &QUOTunblocked&QUOT can be combined with the blocked scans after one has determined the scans were blocked by the continuum and background levels).

One additional consideration in determining the scattered and stray light backgrounds is the fact that the *Copernicus* spectrometer varied in sensitivity both as a function of wavelength and time. For this reason, one cannot use the ratio of the background to the local continuum level determined for one scan (or set of scans) to calculate the background for scans of the same wavelength range taken at a much different time. Instead, one must determine the background for each set of scans using only scans taken at approximately the same time.

NSSDC is a partner of NASA's other astrophysics "active archives" in making astrophysics data accessible. In particular, NSSDC makes IRAS, COBE, and SWAS data network-accessible, while IRSA at Caltech makes other long-wavelength data accessible. X-ray and gamma ray data are accessible from HEASARC at Goddard, and optical and UV data are accessible from MAST at STScI.

NSSDC is the permanent archive for most NASA astrophysics data. NSSDC holds various relatively recent data on CD-ROMs and, on other offline media, many older astrophysics data sets from before the establishment of the active archives. Finally, NSSDC and Goddard's Astrophysics Data Facility provide access to astronomical source catalogs and journal tables through the Astronomical Data Center.

Material credited to STScI on this site was created, authored, and/or prepared for NASA under Contract NAS5-26555. Unless otherwise specifically stated, no claim to copyright is being asserted by STScI and it may be freely used as in the public domain in accordance with NASA's contract. However, it is requested that in any subsequent use of this work NASA and STScI be given appropriate acknowledgement. STScI further requests voluntary reporting of all use, derivative creation, and other alteration of this work. Such reporting should be sent to copyright@stsci.edu.

Interim additional notice: This site also contains material generated, authored and/or prepared by individuals or institutions other than STScI, and those individuals or institutions may claim copyright. Should you desire use of such material at this time, inquiries should be made to those individuals and institutions in accordance with the following:

A catalogue of HST publicly released images on this site may be found at the following location: http://oposite.stsci.edu/pubinfo/pictures.html. If the credit line for an image lists STScI as the source, the image may be freely used as in the public domain as noted above. However, for credit lines listing individuals from other institutions, you will need to contact that institution listed in the credit line to advise you on the copyright policy for that image. If the institution referred to is a US institution, you can go to the American Astronomical Society web site to obtain their contact information (http://directory.aas.org).

Disclaimers

The availability of STScI materials on this web site does not imply the endorsement of STScI or by any STScI employee of any private use of such materials, including, in particular, any commercial use and any use intended to mislead.

Photography: If a recognizable person appears in a photograph, use for commercial purposes may infringe a right of privacy or publicity and permission should be obtained from the recognizable person.

Audio Recordings: Use of a portion or segment of an audiotape, such as talent, narration or music, may infringe a right of publicity or copyright and permission should be obtained from the source.

Video or Motion Picture Recordings: Music or footage copyrighted by others, which is incorporated in a production, may not be used unless permission is obtained from the copyright owner. While in most instances using non-copyrighted segments is permitted, use for commercial purposes of a portion or segment containing talent or a recognizable person may infringe a right of publicity and permission should be obtained from the talent or recognizable person. These guidelines also apply to STScI's "live television" satellite broadcasts.

Any questions you may have regarding the above copyright statement can be directed to copyright@stsci.edu.

Preface

ST-DADS History

In the beginning, the archive system used at the Space Telescope Science Institute (STScI) was the *Data Management Facility*, or DMF. The DMF was developed by STScI in collaboration with the Space Telescope European Coordinating Facility (ST-ECF). Only a limited amount of data could be kept online, and the data were stored in the VAX-specific GEIS format.

The permanent, more capable archive system—the *Space Telescope Data Archive and Distribution Service* (ST-DADS)—was installed September 1994. Developed by Loral and STScI, ST-DADS stores HST data on its optical jukeboxes, provides quick access to data, and distributes those data in the standard astronomical format FITS (Flexible Image Transport System). ST-DADS is now able to deliver data directly to a user's home computer over the Internet.

What's in this Manual?

The *STScI Archive Manual* provides information a user needs to know to access the HST archive via its two user interfaces: StarView and a World Wide Web (WWW) interface. It provides descriptions of the StarView screens used to access information in the database and the format of that information, and introduces the user to the WWW interface. Using the two interfaces, users can search for observations, preview public data, and retrieve data from the archive. Using StarView one can also find calibration reference files and perform detailed association searches. With the WWW interface archive users can access, and obtain information on, all Multimission Archive at the Space Telescope Science Institute (MAST) data, a collection of mainly optical and ultraviolet datasets which include, amongst others, the *International Ultraviolet Explorer (IUE) Final Archive*. Both interfaces feature a name resolver which simplifies searches based on target name.

This manual is organized as follows:

- Chapter 1, "Introduction to the STScI Archive," provides a basic introduction to the archive, describing the data in the archive, the archive system and interfaces, and the support provided by STScI for those using the HST archive.

- Chapter 2, "Getting Started on the Archive System," describes how to access the STScI archive, how to register, how to retrieve data, and how to obtain relevant documentation.
- Chapter 3, ‘‘The World Wide Web Archive Interface at STScI’’, provides hints on how to search and retrieve data from the HST and MAST archives via the WWW interface. It also describes briefly the various MAST datasets.
- Chapter 4, "StarView Tutorials" provides two basic tutorial sessions. The first shows you how to use StarView to select observations and how to retrieve that data. The second describes the use of the calibration reference screens in StarView which allow you to retrieve the best available HST calibration reference files. A short description of some commonly-used screens is also provided.
- Chapter 5, "Archive Search Strategies," offers effective approaches to find information and datasets in the archive.
- Chapter 6, "Advanced Queries", explains how to create custom screens and use Standard Query Language (SQL) to create your own methods of locating archival information.
- Chapter 7, "Additional StarView Topics", describes how to customize the user interface and defaults. It also discusses On-The-Fly Calibration.
- Chapter 8, "HST Catalog Screens," displays snapshots of all the screens in the StarView system together with descriptions of the types of data accessed by each.
- Chapter 9, "Data in the HST Archive," describes the types of files and their contents for HST datasets.
- Two appendices contain a list of archive-related acronyms and a description of the database structure of the HST Archive. The latter will facilitate the construction of custom queries.

What's New in this Manual (v7.0)?

Since the previous incarnation of this User Manual, StarView has been updated and the new WWW interface is now fully functional. The terminal version of StarView (designed for vt100 terminals) has been discontinued and StarView can no longer be run by logging into the guest account on the archive host machine. On-The-Fly Calibration is a reality. The STScI Archive has also expanded by providing access to non-HST datasets, with the creation of MAST. Moreover, two new instruments, NICMOS and STIS, are now on board HST. Some new features of this Manual include:

- The previous manual (v6.0) contained several references to the terminal version of StarView. These have all gone.
- A whole new Chapter 3 describes the WWW interface to access HST and MAST data. It also describes briefly the various MAST datasets.
- Most StarView screens have been rearranged and modified and the updated version is now described. In particular, NICMOS and STIS screens are now available. (Chapter 8.)
- On-The-Fly Calibration (OTFC) screens are discussed. ("On-The-Fly Calibration Screens" on page 185.)
- Chapter 9, ''Data in the HST Archive'', has been completely updated.
- Two of the four Appendices which appeared in v6.0 have been deleted because they were out-of-date. What is now Appendix B "HST Archive Database Description" is an updated, reduced version of that previously available, since most of the information is now on the WWW.
- A version of this manual that will contain minor updates will be available on the WWW at `http://archive.stsci.edu/manual`.

1 Introduction to the STScI Archive

In This Chapter..

Archival research is an important component of the Hubble Space Telescope (HST) program. Calls for proposals for funded archival research (by U.S. investigators) occur regularly with the HST Call for Proposals. However, research utilizing the HST Archive does not have to be funded by the archival research program. The archive is available to any individual with the interest and hardware capabilities required to analyze HST data. The archive is not a repository of pretty, heavily processed pictures; press releases can be downloaded from the World Wide Web (WWW) site maintained by the Office for Public Outreach (OPO) at `http://oposite.stsci.edu/`.

Data in the Archive

The Hubble Data Archive (HDA) contains science data from all completed HST observations and calibration files, such as flat fields, which are used to reduce these data. As of June 1999, the archive contains over 6.4 Terabytes of data, for a total of more than 180,000 science exposures. In addition to all the science data sent to observers and all the calibration reference files, the archive contains engineering files that may be useful for diagnosing some questions about observations. The archive also contains the raw science data stream from HST. While the raw stream is not generally useful to astronomers, STScI can use it to regenerate the Space Telescope Science Data Analysis System (STSDAS) files containing uncalibrated science data. As data are archived, information about observations and the targets is extracted from the headers of the data files and stored in an online catalog.

HST data become available to the astronomical community upon the expiration of a proprietary period. Most general observer (GO) and guaranteed time observer (GTO) observations have proprietary periods of a year, but some observations have shorter or longer proprietary periods. Nearly all calibration observations are made public immediately upon receipt. The archive catalog contains information about all observations that have been made with HST. All public data can be retrieved from the HST archive. Proprietary datasets may be retrieved by GOs and GTOs with the appropriate authorization (contact the archive hotseat at `archive@stsci.edu`).

The Multimission Archive at the Space Telescope Science Institute (MAST) was created in 1997. Taking advantage of its existing archive infrastructure, the STScI archive was expanded by providing access to (mostly ultraviolet) non-HST datasets. The data available through MAST, in addition to those in the HDA, include now the following archives: International Ultraviolet Explorer (IUE), Extreme Ultraviolet Explorer (EUVE), Copernicus (OAO-3), Ultraviolet Imaging Telescope (UIT), Hopkins Ultraviolet Telescope (HUT), Wisconsin Ultraviolet Photo-Polarimeter Experiment (WUPPE), Digitized Sky Survey (DSS), and Very Large Array (VLA) Faint Images of the Radio Sky at Twenty-centimeters (FIRST). STScI plans to incorporate additional ultraviolet and optical data sets into MAST in the future including, among others, data from the Far Ultraviolet Spectroscopic Explorer (FUSE). Support for MAST for non-HST data is provided by the NASA Office of Space Science via grant NAG5-7584 and by other grants and contacts. A more detailed description of MAST is given in Chapter 3.

STScI archive users should consult our WWW page at `http://archive.stsci.edu` for up-to-date archive information. MAST also publishes a newsletter, which is distributed electronically via a mailing list, to provide the latest information about its activities. STScI archive users are encouraged to subscribe to it by sending an e-mail message to `archive_news-request@stsci.edu`. The single word SUBSCRIBE should be included in the body of the message. The newsletter can also be read on the WWW at `http://archive.stsci.edu/archive_news/archive_news.html`.

STScI Archive System

The Space Telescope Science Institute has an archive system called the Space Telescope Data Archive and Distribution Service (ST-DADS). ST-DADS handles HST and FIRST data (and will also archive and deliver FUSE data). In 1998, between 4 and 6 Gigabytes of HST data per day have been archived, while 3 - 4 times as many data have been retrieved by archive users. Under ST-DADS, archived science data are stored and retrieved in the standard astronomical format, FITS.

Other optical-UV data are instead stored in CDROM jukeboxes. Their retrieval is handled by a WWW-based system independent of ST-DADS, under the auspices of the Multimission Archive at the Space Telescope Science Institute.

Other Archives Containing HST Data

Copies of the HST data and the archive catalog are maintained at the Space Telescope European Coordinating Facility (ST-ECF) in Garching, Germany (WWW page at `http://ecf.hq.eso.org/`) and at the Canadian Astronomy Data Centre (CADC) in Victoria, Canada (WWW page at `http://cadcwww.dao.nrc.ca/`). The Astronomical Data Analysis Center at the National Astronomical Observatory of Japan (NAOJ; WWW page at `http://adac.mtk.nao.ac.jp/`) will also soon hold copies of HST data and of the archive catalog. There is a significant amount of collaboration and coordination between the ST-ECF and the CADC to assure that the data and the basic services provided are similar. However, the archives are not identical. Therefore, European and Canadian astronomers should consult the ST-ECF and CADC WWW pages or contact the ST-ECF (`stdesk@eso.org`) or CADC (`cadc@hia.nrc.ca`) for information about using their archive systems.

Publication of STScI Archival Research Results

The results of investigations with HST archive data are generally published in the scientific literature. All publications based on these data should carry the following footnote:

> *"Based on observations made with the NASA/ESA Hubble Space Telescope, obtained from the data archive at the Space Telescope Science Institute. STScI is operated by the Association of Universities for Research in Astronomy, Inc. under NASA contract NAS 5-26555."*

If the archival research was supported by a grant from STScI, the publication should also carry the following acknowledgment at the end of the text:

"Support for this work was provided by NASA through grant number ________ from the Space Telescope Science Institute, which is operated by AURA, Inc., under NASA contract NAS 5-26555."

Please send one preprint or reprint of each refereed publication based on HST archival research to the following address:

Librarian
Space Telescope Science Institute
3700 San Martin Drive
Baltimore, MD 21218 USA

Publications based on non-HST MAST data should carry the following acknowledgment:

"Some/all of the data presented in this paper were obtained from the Multimission Archive at the Space Telescope Science Institute (MAST). STScI is operated by the Association of Universities for Research in Astronomy, Inc., under NASA contract NAS5-26555. Support for MAST for non-HST data is provided by the NASA Office of Space Science via grant NAG5-7584 and by other grants and contract"

The User Interfaces

There are two different ways to access data in the STScI archive: XStarView and a WWW interface.

XStarView

As part of the ST-DADS effort, STScI developed the StarView interface to the HST archive. Using StarView, one can ask common questions about the data in the archive, determine whether the data are public, and retrieve the data of interest. Starview was originally available in two versions, a CRT version designed for vt100 terminals and emulator screens (called StarView) and an X-Windows version (called XStarView). Only XStarView is currently available.

XStarView not only provides a very intuitive way of accessing the HST Archive Catalog, but also allows one to preview a compressed version of the public data in the archives. XStarView runs on various platforms and can be installed at one's home site. (More details on the client-server software can be found in "Distributed StarView" on page 11). Some non-HST MAST data files can also be accessed through the XStarView interface, namely the Digitized Sky Survey and the FIRST survey.

WWW Interfaces

The HDA can also be accessed via our WWW interface at `http://archive.stsci.edu`. Most users will find the WWW interface more convenient to use, as it does not require any client-server software installation and can be accessed by any Web browser. Note however that the WWW interface does not provide all the functions of XStarView as regards HST data. A Java based, WWW interface is currently under development (StarView II). This will include all of XStarView capabilities and will replace XStarView altogether.

Various WWW interfaces, all accessible via the main MAST WWW page available at `http://archive.stsci.edu/mast.html`, are the only option for most non-HST MAST data.

Retrieving Data

If you want to retrieve HST data, you must be a registered archive user (see "Registering as a User" on page 10). Once you have an archive password, you can retrieve data by using XStarView or our WWW interface to select datasets and choosing where you want the data written—on the archive computer staging disk from which you can copy using anonymous FTP (HOST option), on a magnetic tape that we mail to you (TAPE option), or directly to your home computer (NET option).

If a user wants to retrieve a large number of datasets it is better to submit several smaller requests than one large one. So one should try to keep the number of datasets in each request under 100 - 200.

Users with a large volume of data to retrieve, a very slow electronic connection, and access to an 8mm or DAT tape drive should choose the TAPE option. A tape can be generated and mailed on the same business day.

No registration is required to access non-HST MAST data.

User Support Services

The Archive Branch (AB) at STScI is committed to providing outstanding and timely support to archive researchers. We provide assistance and advice on methods and strategies for finding information in the archives and provide a hotseat staff for researchers who have specific problems or questions about using the archive. Archive researchers who need extensive advice on search strategies or help analyzing their astronomical data can visit STScI.

Support for Archival Research

The Archive Branch (AB) at STScI is responsible for the management, scientific and technical oversight, and operation of the HST archive. AB staff also support astronomers who wish to use public data from the HST archive for their own research. To provide assistance for archive researchers, the AB staff includes archive specialists (with bachelor or masters level degrees in physics or astronomy) and archive scientists (Ph.D astronomers). The support provided by the AB includes:

- Answering specific questions about data in the archives and methods for retrieving those data.
- Maintaining a WWW site for archive services (`http://archive.stsci.edu/`).
- Providing advice on strategies for searching the archives.
- Responding to problems identified by users.
- Setting up accounts for users who wish to retrieve data.
- Authorizing GOs and GTOs who wish to retrieve their own proprietary data.
- Writing data tapes for users.
- Providing support for users who visit STScI.

Archive Branch staff will not normally do an astronomer's archive search, generate requests for data, or reanalyze data from the archive. Archive Branch staff will provide assistance and documentation so that archive researchers can perform these tasks.

Archive Hotseat

You can obtain help or answers to any questions that you may have about the HST archive by sending e-mail to `archive@stsci.edu`, or by phoning (410) 338-4547 Monday through Friday, 9 a.m. to 5 p.m. Eastern time.

The hotseat staff will respond to questions concerning the StarView and WWW user interfaces, the archive and archive databases, and data tapes provided by STScI. Hotseat personnel establish the accounts needed to retrieve data from the archive. The hotseat staff will also provide advice concerning basic strategies, and will investigate and document all problem reports. The archive hotseat staff may not always know how to solve a problem, but they are responsible for finding out who does know the answer and for continuing to work with you until the problem is resolved. All initial communication from the user community to the archive—both inside and outside of STScI—should be directed to the archive hotseat.

Visits

Archive researchers who need extensive advice on search strategies or help analyzing their archival data may visit STScI. To make sure that the Archive Branch is able to provide the help needed during a visit and to set up the appropriate computer accounts, archive visits must be approved by the AB branch chief at least two weeks in advance. To arrange a visit, contact the archive hotseat. The number and duration of visits is limited by the staff that we have available. If a conflict arises, funded researchers will have priority over those who are unfunded.

Questions and Comments

We welcome your comments and questions about the archive in general or about archive user support. As discussed above, communication to us regarding all aspects of the archive should normally be directed to the archive hotseat (e-mail: `archive@stsci.edu`, or phone (410) 338-4547). This will allow Archive Branch staff to respond to your requests even when individual members of the group are away. If you feel your needs are not being adequately addressed through the hotseat however, please contact the Archive Branch Chief, Marc Postman (send e-mail to `postman@stsci.edu` or phone (410) 338-5072).

2 Getting Started on the Archive System

In This Chapter..

This chapter describes how to access the STScI archive via *XStarview* and the World Wide Web interface, how to register as a user, how to retrieve data to your home system, and how to obtain relevant documentation.

Accessing the Archive

As described in Chapter 1, there are two ways of accessing the STScI Archive: through the program *XStarView* and through a WWW interface. Both ways let the user browse the Archive for data of interest and preview publicly available data. After you register as an archive user, *XStarView* and the WWW interface will also let you retrieve data from the Archive.

STScI used to maintain an archive host computer from which one could run StarView by logging in as a guest. For security reasons this service has been discontinued. All users need to install the distributed version of StarView directly on their local machine (a ten minute task on Sun workstations). You may find that another member of your department has already installed StarView on your cluster, in which case, you should be able to start examining the STScI Archive simply by typing the command:

```
% xstarview &
```

Be sure to read the welcome screen when you start *XStarView*. The welcome message is retrieved from STScI, and we use it to post news items. More information on distributed StarView can be found on page 11. Chapter 4 of this manual is a tutorial to using the archives with *XStarView* and provides the user with all the basic information one needs to access the STScI archive.

Alternatively, one can use our WWW interface at `http://archive.stsci.edu/mast.html` to access all the HST and non-HST data available from MAST, the Multimission Archive at the Space Telescope Science Institute. The WWW interface can be accessed by any Web browser from a range of hosts, including PCs and Macintoshes. Chapter 3 of this manual provides more information on this interface.

Our WWW site contains also the most up to date information regarding the Archive, including documentation, recently added features, forms for user registration, and other archive services.

Registering as a User

A guest user has full access to the HST catalog and previews of public data. However, *only registered users can retrieve HST data*. You can register as an HST Archive user by using our WWW form at `http://archive.stsci.edu/registration.html` or by sending e-mail to `archive@stsci.edu`. You will be notified by e-mail of your registration as an archive user within two working days of the time when your request is received and you will be provided with a username and a password. If your archive account is idle (i.e., no data have been retrieved) for more than one year, it will be deactivated. Reactivate expired accounts by contacting the archive hotseat.

Registration is not necessary to access non-HST data which are not delivered by ST-DADS. This includes all MAST data (apart from FIRST data retrieved via *XStarView*).

Authorized Users and Proprietary Data

HST GOs and GTOs can retrieve their proprietary data from the archive. To do so, they must be registered and authorized users. GOs and GTOs desiring this option must register with the archive and send e-mail to `archive@stsci.edu.` Only PIs may authorize anyone to access their data. If a co-I wishes access to their HST data, they must have the PI on the proposal send the archive e-mail stating the proposal ID number and the identities of anyone who should be able to retrieve the data. (Other authorization pathways may be in effect in the future, but this method will always be available.) We note that for security reasons, proprietary data cannot be retrieved to the staging disk even by authorized users. All proprietary data must be either directly retrieved to the user's machine or to tape. Either of these options can be specified from *XStarView* or the WWW interface.

Distributed StarView

The client-server version of StarView runs on your local machine and sends a request to our data base server when it needs information. The distributed version is the only one currently available, as users can no longer log in on the archive host computer. Distributed StarView is available for Unix for Sun SparcStations running SunOS 4.1.3, SunOD 5.5.1, and DEC Alpha systems running Digital UNIX V4.0 (Rev. 386). It typically takes only a few minutes to install StarView on Sun workstations. Installation on VMS systems (VAX or DEC Alphas running OpenVMS) is more time-consuming, but it is possible if you are already running the following software:

- OpenVMS, VAX or Alpha V6.2.
- DECWindows Motif Version 1.2-4 for OpenVMS
- CISCO MultiNet V4.0 Rev A-X

Instructions for ftp'ing the relevant software or automatically downloading it over the World Wide Web can be found in the Archive WWW page `http://archive.stsci.edu/dist_starview.html.` This site will contain the most recent installation instructions appropriate to the current version of *XStarView*.

Getting Your Data

HST Data

Registered users can retrieve HST data from the STScI Archive by submitting a data retrieval request through *XStarView* or the WWW interface. Users will be asked to specify whether to retrieve data directly to their home machine (NET), to the Archive staging disk (HOST), or to tape (TAPE; default is Exabyte). For *every* request you will be asked for your archive username and password. (Note that the password that you were given when you registered can be changed from the Commands pull-down menu in

XStarView.) For a NET retrieval, you will also be required to give your home username and password so that data can be written to your disk.[1] For large data requests (more than 500 Megabytes) and slow Internet connections, consider requesting a tape of the data.

After you have submitted your request, the archive system will process it. You will be notified immediately by e-mail when ST-DADS has accepted the request and again when ST-DADS has completed processing the request, indicating whether or not the transfer was successful. The messages will go to the e-mail address that you specified on your archive account registration form.

How long a retrieval takes depends on a variety of factors, including: the type of data in the request (some kind data are stored offline and requires an operator's intervention), the size of the request (the larger the request the longer it takes, both to move the request up the queue, and to retrieve the data), the number of requests in the system at the time, and the destination of the request (the internet connections between STScI and some sites, especially those overseas, is sometimes a significant source of delay).

If everything is running smoothly, one should expect a median turn around time of a few hours. If it takes more than one day, and you do not think any of the factors listed above are playing a significant role, please contact us.

If you choose to retrieve the data to the archive host machine (HOST option), the data will be written to a subdirectory of the Archive staging disk[2]. Each data retrieval request will be in its own subdirectory, identified by the request ID number (which will be included in the notification message). To find your data, from your home account type:

```
% ftp archive.stsci.edu
% login: anonymous
ftp> ls (to find your directory, e.g. USER0123)
ftp> cd USER0123
ftp> ls
```

After locating your data on the archive host, you can transfer it across the Internet using FTP (as described in the next section). Alternatively, you may specify a data location at your own site, or for large requests, ask for an Exabyte tape, which will be sent to the address you specified when you registered.

The following section explains how to transfer your data. Because we have many users, the disk space available to each user

1. External users may prefer to specify an anonymous incoming ftp site at their institution. Notice however that, when using our WWW interface, we protect your destination information with the same kind of secure Web mechanism that is used by commercial sites.

2. Note that proprietary data cannot be retrieved to the host machine archive.stsci.edu even by authorized users.

within the data directory is limited. The files you create in the data directory are temporary and are deleted automatically after two days. However, we would appreciate notification that you have completed copying over your retrieved files so that we may delete them. (Send email to `archive@stsci.edu`.)

MAST Data

Non-HST MAST data can be obtained via the MAST WWW pages, all accessible from `http://archive.stsci.edu/mast.html` by selecting the data of interest. Most MAST data can be currently retrieved via FTP by ‘‘clicking’’ on the file names. More information on MAST searches and retrievals is provided in Chapter 3 of this manual.

Using FTP

If you have used the HOST option to retrieve your data to the archive host computer (archive.stsci.edu), you must then transfer your files to your local computer via anonymous FTP *from your own computer*. You can also use FTP to acquire any of the ASCII files, such as the PostScript versions of the *HST Archive Manual*. See Table 2.1 for examples of ftp sessions.

Sample Function	Unix Commands

Retrieve HST data (*registered* users only) from the data directory as named in the acknowledgement e-mail - in this case, “dir0129”	`%ftp archive.stsci.edu (or stdatu.stsci.edu)`
	`(login as “anonymous”)`
	`ftp> cd dir0129`
	`ftp> ls`
	`ftp> binary`
	`ftp> mget x*`
	`ftp> bye`

Retrieve PostScript and/or text versions of manual, abstracts, catalogs, general information. Those files that end in .Z can be uncompressed with the unix command “uncompress” and those that end in .gz require the command “gunzip”. The uncompressed files are also available.	`ftp archive.stsci.edu`
	`(login as “anonymous”)`
	`ftp> cd pub/manuals (or pub/forms or pub/hdf etc.)`
	`ftp> ascii`[a]
	`ftp> ls`
	`ftp> mget *.ps.Z` *(or whatever)*
	`ftp> bye`

a. As appropriate. In the case of the Hubble Deep Field images, “binary” would be the appropriate datatype.

Table 2.1: File Access Commands for Archive Users

Documentation on the Telescope, Instruments, and Data

You can obtain a wide range of technical documentation on the telescope, its instruments, and HST data from the Science Support Division helpdesk at STScI. The Science Support Division Help Desk, serves as a central contact point between the scientific community and STScI and central clearinghouse for hotseat questions. All documentation requests and data/instrument questions should be directed to `help@stsci.edu`.

Science Support Division Help Desk
Space Telescope Science Institute
3700 San Martin Drive
Baltimore, Maryland 21218 USA
Phone: (410) 338-1082

Some of the documentation available includes the following. These documents are also distributed to astronomical libraries.

- *HST Archive Manual*
- *HST Data Handbook (I & II)*
- *STSDAS User's Guide*
- *FOC Instrument Handbook*
- *FOS Instrument Handbook*
- *GHRS Instrument Handbook*
- *NICMOS Instrument Handbook*
- *STIS Instrument Handbook*
- *WF/PC Instrument Handbook*
- *WF/PC 2 Instrument Handbook*
- *FGS Instrument Handbook*
- *OTA Handbook*
- *Target Acquisition Handbook*s
- *Calibration Status and Plan*s
- *The GO and GTO Observing Programs*
- *STEIS instructions*

HST Data Handbook

The *HST Data Handbook* provides a comprehensive guide to all major aspects of HST data reduction and analysis. The handbook describes the contents of each dataset, how to display HST images and spectra, ways to identify and correct problems in your HST data, and instructions for doing common analysis and image reconstruction tasks. The handbook assumes no prior knowledge of HST data, the IRAF or STSDAS systems, or any specific knowledge of HST instruments, other than that required to have prepared an observing proposal.

The latest version (3.0, October 1997) of the handbook adopts a modular organization that lends itself to frequent updates. Individual chapters may be updated at any time as new information becomes available.

The HST Data Handbook is now split into two volumes:

- Volume I, Current Instruments: Includes those instruments currently active (1997) on the telescope; FOC, FGS, NICMOS, STIS, and WFPC2;
- Volume II, Heritage Instruments: Includes instruments removed from the telescope; FOS, GHRS, HSP, WF/PC-1.

The *HST Data Handbook* can be requested through the archive hotseat (`archive@stsci.edu`) or the SSD help desk. It is also available on-line at `http://www.stsci.edu/documents/data-handbook.html`.

Finding Documentation

By using anonymous ftp to access archive.stsci.edu and exploring the `pub` directory, the user will find subdirectories that contain files of interest, including special HST data collections from some Key Projects, special HST-related user-generated data, and the Hubble Deep Field, documentation and forms. These files are available to anyone with access to the Internet and ftp software. For example, to get a copy of the most recent archive manual:

```
>ftp archive.stsci.edu
>login: anonymous
>passwd: your e-mail address
ftp> cd pub
ftp> ls [Lists the available directories]
ftp> cd manuals
ftp> ascii
ftp> mget archive_manual*.ps.Z
ftp> bye
```

Example: How to use anonymous ftp to get archive manuals.

If the files have a capital Z appended to their names (as in the above example), you will need to run a Unix utility called `uncompress` to expand the files to their original form, e.g. `uncompress archive_manual01.ps.Z` will restore the file `archive_manual0l.ps`. Those files that end in .gz were compressed with the utility `gzip` and can be uncompressed with the utility `gunzip`.

Most of the HST and Archive documentation is also available on the WWW. For example, many documents are accessible at `http://www.stsci.edu/ftp/documents/html/documents.html`.

Manuals

PostScript files of the latest version of the *HST Archive Manual* are kept in the `pub/manuals` directory accessed by anonymous ftp to stdatu.stsci.edu.

The *HST Archive Primer* used to provide all the basic information needed to search the HST catalog and to retrieve HST data using the STScI archive host computers. The *Primer* is not available anymore, as all the information it provided is now given in the first three Chapters of this manual. This document, the *HST Archive Manual*, provides more detailed information about StarView and its higher level functions, and about the design of the HST Catalog and Archive.

On-line access to this document is also available at `http://archive.stsci.edu/hst/documentation.html`.

Forms

Forms related to archival research, such as the *HST Archival Data Request*, *HST Data Distribution*, *HST Archive Account Registration*, and *HST Archival Research Visit Request*, are maintained as PostScript files in the `pub/forms` directory accessed by anonymous ftp to stdatu.stsci.edu. Some of these forms can also be found in electronic format on the Archive WWW pages.

Exposure Catalogs

The Archived Exposures Catalog (AEC) and the Planned and Archival Exposure Catalog (PAEC) are located in the `pub/catalogs` directory. Both the AEC and PAEC come in two versions—one that contains all targets and is ordered by RA and one that contains just solar system targets and is ordered alphabetically by target name. This directory also contains the catalogs of the text in proposal abstracts and proposal titles.

The AEC is updated monthly. The AEC is an ASCII list of observations in the HST Archive and contains information such as the target name, position, instrument, mode, and date on which the data become non-proprietary (publicly accessible). Information provided in the AEC is a selected subset of the keyword information stored in the HST catalog. The AEC is produced through an automated search of the catalog. For more information, see “ASCII Catalogs” in the Archive Manual. The AEC is also available on the WWW at `http://archive.stsci.edu/hst/aec.html`.

The PAEC is an ASCII listing of all HST targets approved for observation including all general observer (GO) and guaranteed time observer (GTO) observations. Thus, the PAEC includes information for all executed and planned HST observations. The PAEC is also stored as a table in the HST archive database and can be examined from within *XStarView* using the <Duplication Checking> search screen.

Target RA and Dec in the AEC and PAEC are in J2000 coordinates.

Using STSDAS/IRAF to Analyze Your Data

You can analyze or recalibrate HST datasets using STSDAS, which can be installed under IRAF. A comprehensive discussion of STSDAS and IRAF features or a tutorial on how to use the software is beyond the scope of this manual. Contact the STSDAS hotseat `(help@stsci.edu)` for answers to any STSDAS-related questions that you may have. To learn how to use this data analysis package, you can request copies of the documentation by sending e-mail to `help@stsci.edu`. Various STSDAS and software related documentation is also available on-line at `http://www.stsci.edu/ftp/documents/html/documents.html`.

When a Retrieval Fails

Occasionally, a retrieval fails because of a network timeout, disk space inadequacy, or other reasons. The staff at `archive@stsci.edu` are available for any questions about the request. (See page 5 for full help desk information.) If after checking with the support staff you find that the retrieval request itself was sound, you can resubmit a retrieval request without having to go through StarView. The program **sv_dads_retrieve** allows you to retrieve files directly from DADS. It is, in fact, the program that StarView calls during a retrieval request.

You invoke **sv_dads_retrieve** on a .req file from a previous request. These files are written by StarView into the directory `.svdata` on Unix systems or into `[.svdata]` under sys$login in VMS. (These directories are by default written into the home directory; they can be redirected by setting a local environment variable SV_DATA_DIR. See Hint on page 30.) The .req files are named after the date and time when the request was sent; for example, 940926_163536.req was sent on 26 Sep 1994, at about 4:35 pm EST. Alternatively, you could construct a `.req` file from scratch, using a previous req file as a template. If the passwords are left out, **sv_dads_retrieve** will ask for them.

The following examples show how to start up **sv_dads_retrieve** on different operating systems.

On Unix systems:

```
% source /usr/local/cmo/starview/svinit.csh
% sv_dads_retrieve
```

On the VMS Science Cluster at STScI:

```
$ @DISK$ABELL:[DMFOPS.STARBASE.STARVIEW]SVINIT
$ SV_DADS_RETRIEVE
```

On STOSC (the Institute operations support cluster):

```
$ @DISK$ZARDOZ:[STARBASE.STARVIEW]SVINIT
$ SV_DADS_RETRIEVE
```

3 The World Wide Web Archive Interface at STScI

In This Chapter..

This chapter describes the World Wide Web interface to the STScI archive and provides hints on how to search and retrieve data from the HST and Multimission Archive at the Space Telescope Science Institute (MAST). It also describes briefly the various MAST data sets. Readers should be aware that the archive WWW pages are still evolving so the description given here will be of a general nature. The HST page is available at `http://archive.stsci.edu`, while the MAST page is available at `http://archive.stsci.edu/mast.html`.

The HST WWW Interface

The HST WWW archive interface is one of the two user interfaces to the Hubble Space Telescope data archive (the other one being StarView). It provides a fast way of doing relatively simple searches for existing data in the archive. Using the WWW interface one can:

- Browse the contents of the archive;
- Select observations of interest;
- Preview public data;
- Retrieve data from the archive for scientific analysis.

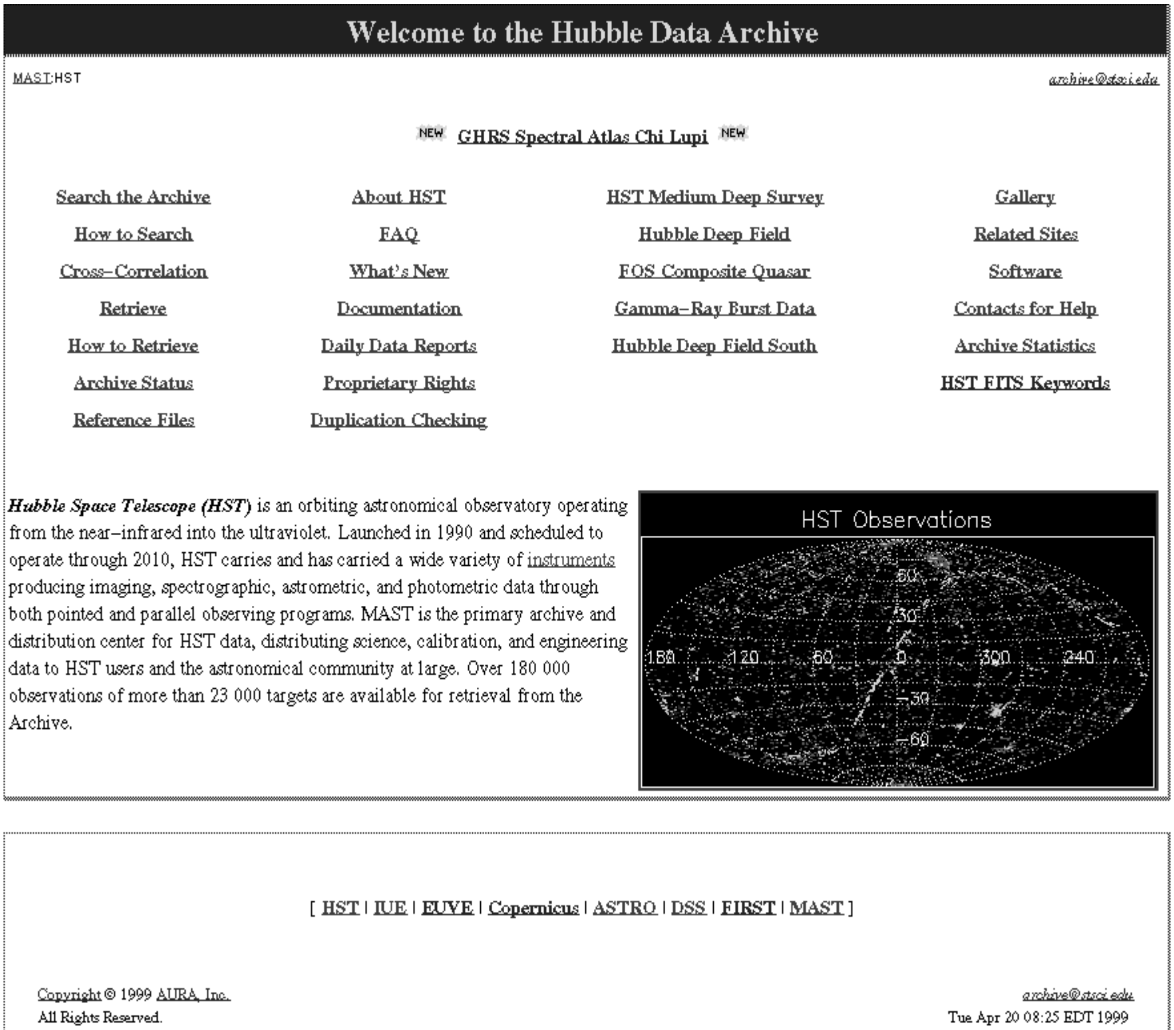

Figure 3.1: The main HST WWW page at `http://archive.stsci.edu.`

The main HST WWW page is shown in Fig. 3.1. The page not only provides access to the archive interface but also allows users to access a variety of up-to-date archive information, ranging from archive status, reference files, latest developments, on-line documentation, etc. A list of frequently asked questions is also available.

We now describe the main features of the HST WWW interface.

Searching the HST Archive on the Web

The search page, accessible from the main HST page (**[Search the Archive]**), allows the user to search the HST archive on a variety of parameters, ranging from object name and position, to observation date, observer's name, and program ID, to instrument and observation band. The name of the astronomical object can be resolved using either the NASA/IPAC Extragalactic Database (NED) or the Set of Identifications, Measurements and Bibliography for Astronomical Data (SIMBAD) for the resolver, by using the **[Resolve]** button. The search form will then be redrawn with the object's right ascension and declination entered as defaults in the RA and Dec fields. Resolving an object name will not change any other choices made in the form. (One does not have to hit the **[Resolve]** button. If one enters an object name, selects either SIMBAD or NED, and then hits the **[Search]** button, the script will get the coordinates before doing the search.)

Archive users should always use object-name resolution to find observations of fixed targets in the database. This is the most reliable way to look up observations, because the observer could have specified any name at all. The SIMBAD and NED object name resolvers can only resolve the names of fixed astronomical object. In the case of objects with variable coordinates (planets, comets, etc.) the search should be done by typing the source's name, embedded in wild card delimiters (e.g., *MARS*), in the object name field, selecting at the same time the **[Don't Resolve]** button.

Archival researchers interested in finding HST observations of a particular class of sources should use the ‘‘Target Description’’ field. This includes a short description of the target, supplied by the observer during the Phase II (planning) process. Although these descriptions may not always be accurate (one observer's CLUSTER OF GALAXIES may be another's ELLIPTICAL), they are usually a good starting point. However, care should be taken in their use: for example, specifying *QSO* in this field will find all targets with this description but will not find the *QUASAR* ones. (To do that one should specify ‘‘*QSO* *QUASAR*’’.) Users are strongly encouraged to check the up-to-date list of all target descriptions currently in use. This is generated automatically every day and posted on the WWW at `http://archive.stsci.edu/hst/daily/target_descriptions.html.` Datasets matching a given description and a particular instrument can be found simply by ‘‘clicking’’ on the hyperlinks in the page. The cross-correlation page, described below, provides a more reliable way to search for specific (selected) classes of astronomical objects.

Some fields can take ranges as input. Namely: the radius, observation date, exposure time, release date, and archive date fields. For example, one can search in a region between 3 and 10 arcminutes from a target by entering “3..10” in the radius field. Or by typing “> Dec 9 1998” in the observation date field one will get all observations obtained after that date.

Users can obtain help on a particular field by ‘‘clicking’’ on the link above that field. A **[Help]** link for the whole search page is also available.

Previewing and Retrieving Data

After filling out the search page and ‘‘clicking’’ on the **[Search]** button, the search interface returns a list of datasets matching the query submitted by the user. (The default is 100 records but this can be changed by using the **[Maximum number of hits]** button on the search page.)

The list includes various columns with target parameters namely target name (as given by the proposer), coordinates, instrument, operating mode, dataset name, etc. The default output columns can be modified by pressing the **[Custom]** radio button and selecting the columns of choice from the list underneath ("Mark" is pre-selected). The output columns will be in the order in which they appear in the list.

The user might want to have a ‘‘quick look’’ at the data before retrieving them. If the target name is hyperlinked, then a preview image or spectrum is available for that observation. Clicking on the target name in that case will bring up the preview form (which lets the user select the format of the preview). Occasionally, one will see target names like PAR, UNKNOWN-TARGET, and so on; these are (most likely) parallel observations, which are observations done by one instrument while another one is making the primary observing of the telescope's visit. Previews are obviously not available for proprietary data.

The **|More info|** column provides links to other pages to obtain additional information on the target. Namely, the Digitized Sky Survey (**DSS**) link displays an image of the field of the target overlaid with the HST field of view, the **[NED]** link searches NED, which provides basic data and references for extragalactic sources, the **[IUE]**, **[EUVE], [HST]**, and **[FIRST]** links start a search for the same target in these archives (see next section).

All datasets have a **[Mark]** button for retrieval (records with a @ character next to the button are proprietary and may only be retrieved by authorized users). The user can mark the datasets of interest to submit them for retrieval to DADS. This will produce a screen with a list of only the marked datasets. The list can then finally be submitted to DADS by filling in a WWW form with the archive username and password, delivery option (NET, HOST or TAPE), and type of files requested. As described in detail in Chapter 2, the archive system will use e-mail to first acknowledge acceptance of the request and then to inform the user when the request has been completed.

Cross-Correlations

Another WWW interface, available from the main HST page (**Cross-Correlation**) and accessible at `http://archive.stsci.edu/search/`, enables the cross-correlation of an Active Galactic Nuclei (AGN) catalog, a galaxy cluster catalog, and a star catalog, plus any user-supplied list of positions, with the HDA. Individual HST instruments, each with a different correlation radius, can be selected.

This is meant to facilitate archive searches for specific classes of astronomical sources. Using this interface, for example, one can select AGN by class, redshift, magnitude, and 6 cm radio flux from a catalog based on Véron-Cetty & Véron (1996), ESO Scientific Report n. 17. The same tool allows one to cross-correlate these catalogs with other MAST missions, as described below.

A user-supplied file can be used to cross-correlate a list of sky positions with the HDA. The input file needs to have one entry per row, with each row containing columns delimited by either tab, comma, pipe, semicolon, or colon.

Duplication Checking

This interface was designed to facilitate duplication checking by proposers who are writing their Phase I, or initial, proposals to apply for HST time. An observation is defined as duplicating a previous one if it is on the same astronomical target, with the same or similar instruments, a similar instrument mode, and a similar spectral range. Proposers must check their proposed observations, identify possible duplications and justify them. Available at `http://archive.stsci.edu/hst/duplication_checking/`, this interface allows a user, by simply entering her/his proposal ID or name, to check for duplications amongst cycle 7, 8, and 9 proposals. (This is especially useful for cycle 6 and 7 PIs, who are now *required* to check for programs conflicting with their own observations.) For more complex duplication-checking one should use the interface at `http://archive.stsci.edu/cgi-bin/duplication.` Note that because these interfaces find duplication candidates by position, they are not appropriate for finding duplications of solar-system observations. In that case, observers can use the Planned and Archived Exposures Catalog (PAEC), in particular, the solar system version, available at `http://archive.stsci.edu/hst/paec.html.`

PDF “Paper Products”

This interface allows users to search for, and display, the HST observation summaries now offered in Portable Document Format (i.e., PDF). These documents, formerly available only in hardcopy form and referred to as the HST "paper products", provide a quick first look at the data, drawing on information in the PDQ file. The WWW interface is available at `http://archive.stsci.edu/hst/pdf_home.html`.

The page can be used to select various search criteria to locate particular PDF files. Submitting the form without entering any criteria will return the entire list of available documents. By default, up to 100 entries are returned. Each row of the search result table describes one PDF file. To see a summary of the observations contained within each file, click on the **contents** entry. The search page also contains links to the requested PDF files. Clicking on the file names will display the PDF file using Adobe Acrobat Reader. The PDF documents are password protected (unless the proposal is a calibration program) and you will need your archive name and password to access documents. We note that this interface is not intended for general archive users but specifically for PIs of HST programs.

The MAST Data Sets

The Multimission Archive at STScI has been developed to support a variety of astronomical data archives, with the primary focus on scientifically related data sets in the optical, ultraviolet, and near-infrared parts of the spectrum. MAST is funded by NASA's Office of Space Science through a grant from NASA and other grants and contracts. Initially set-up to hold, with the Hubble Data Archive, the International Ultraviolet Explorer archive, MAST has evolved by holding, or providing links to, many other missions or projects. These can be accessed through the MAST page at `http://archive.stsci.edu/mast.html`. MAST data, in addition to those in the HDA, include, as of June 1999:

- *International Ultraviolet Explorer (IUE) Final Archive*. This contains over 104,000 spectral images of approximately 10,000 individual astronomical sources (covering the 1,200 to 3,350 Å range) obtained by IUE over the course of its lifetime (from 1978 to 1996). Experienced IUE staff members are also available at MAST to assist researchers working on IUE data.
- *Copernicus Archive*. This includes individually scanned and averaged far- (900 - 1,560 Å) and near- (1,650 - 3,150 Å) ultraviolet spectra of 551 sources, primarily bright stars, obtained by the Copernicus satellite, otherwise known as the Orbiting Astronomical Observatory 3 (OAO-3), from 1972 to 1981.
- *Extreme Ultraviolet Explorer (EUVE) Archive*. At present, this contains spectroscopic observations (in the 70 - 760 Å range) of about 400 sources, mostly galactic. EUVE, launched in 1992, is still operational.
- *Ultraviolet Imaging Telescope (UIT) Archive.* This contains about 1,600 images of more than 200 targets (covering the 1,200 - 3,300 Å range) obtained by UIT as part of the ASTRO-1 and ASTRO-2 Space Shuttle missions.
- *Hopkins Ultraviolet Telescope (HUT) Archive*. This includes about 500 ultraviolet spectra (in the 825 - 1,850 Å range) of more than 300 targets obtained by HUT as part of the ASTRO-1 and ASTRO-2 Space Shuttle missions.

- *Wisconsin Ultraviolet Photo-Polarimeter Experiment (WUPPE) Archive*. WUPPE was designed to obtain simultaneous ultraviolet spectra and polarization measurements from 1,400 to 3,200 Angstroms. It collected about 400 observations of roughly 200 targets during the ASTRO-1 and ASTRO-2 Space Shuttle missions.
- *Digitized Sky Survey (DSS)*. The Catalogs and Surveys Branch of the STScI has been digitizing the photographic Sky Survey plates from the Palomar and UK Schmidt telescopes in order to support HST operations and provide a service to the astronomical community.
- *Faint Images of the Radio Sky at Twenty-centimeters (FIRST) Archive*. The FIRST project is designed to produce a radio survey at 20 cm (1.4 GHz) of over 10,000 square degrees down to a flux of 1 mJy. STScI provides access to the radio images and the source catalog, which currently includes about 437,000 entries.

STScI plans to incorporate additional ultraviolet and optical data sets into MAST in the future, including, among others, data from the Far Ultraviolet Spectroscopic Explorer (FUSE), currently scheduled for launch in mid 1999.

The MAST WWW Interface

The MAST WWW interface represents the only way to access most non-HST data (DSS and FIRST data are also available via StarView). Using this interface one can:

- Browse the contents of MAST;
- Select observations of interest;
- Preview data;
- Retrieve data from the archive for scientific analysis.

The main MAST WWW page is shown in Fig. 3.2. The page not only provides access to the MAST archive interfaces but also allows users to access a variety of up-to-date information, ranging from latest developments, on-line documentation, and data analysis software. A list of frequently asked questions is also available.

A simple form allows users to match the desired data parameters, in terms of wavelength range (from radio to extreme UV) and type of data (images, spectra or other, which include polarimetric and astrometric data), with the relevant archive(s)/mission(s). (For example, a search on “Near UV Images” returns WF/PC, WF/PC2, UIT, and STIS.) Additionally, every MAST mission has its own WWW page, which provides access to the search interface and also gives information about the mission.

We now describe the main features of the MAST WWW interface.

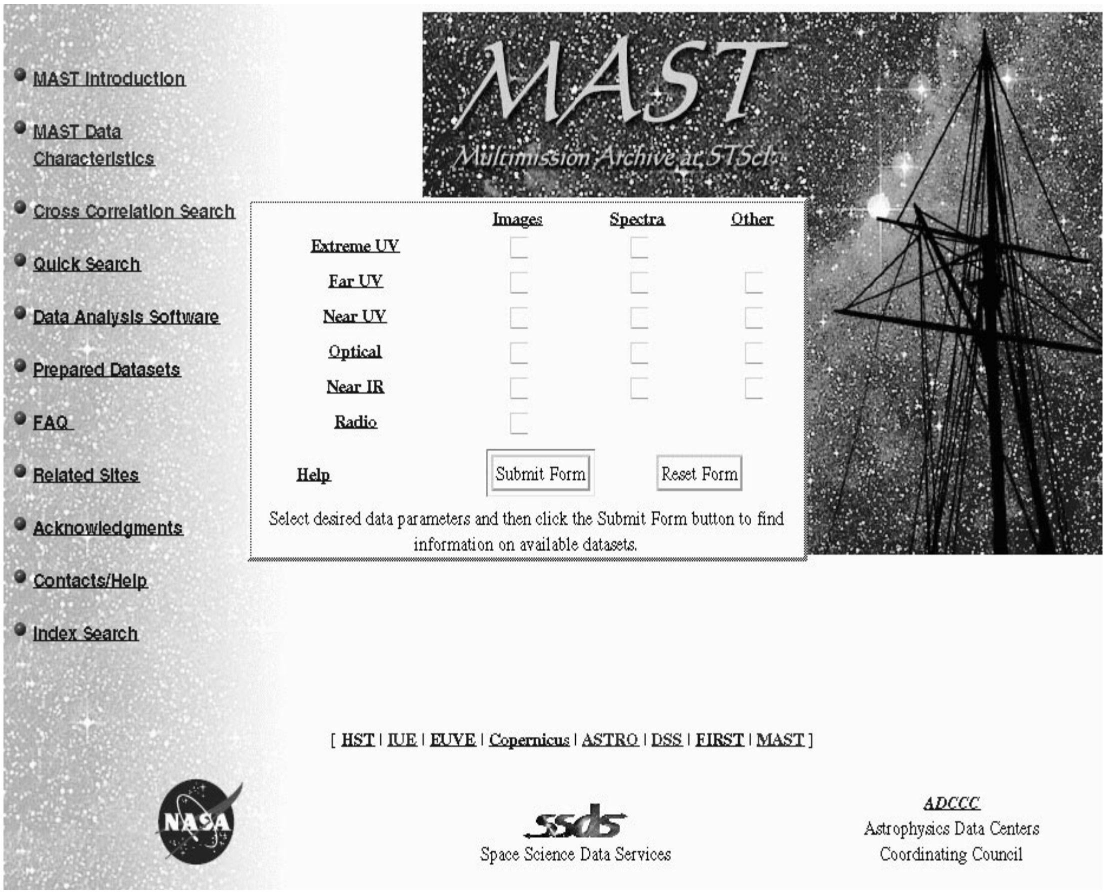

Figure 3.2: The main MAST WWW page at `http://archive.stsci.edu/mast.html`.

Searching the MAST Archive

A simple search of all MAST archives can be done using a "quick search" tool at `http://archive.stsci.edu/quick_search.html/`. By entering the name of a fixed target to be resolved, or the J2000 right ascension and declination separated by a comma, the user is returned with a list of all observations of that source in the MAST archives. Clicking on the mission (or HST instrument) link opens up another window with the specific search page already filled out with the coordinates of the object.

Every MAST mission, in fact, has its own search interface, with mission specific fields, but most interfaces are modeled after the HST one so STScI archive users should find them relatively familiar.

All pages allow the user to search a given archive on a variety of parameters, ranging from object name and position, to observation date, observer's name, and instrument. As for the HST interface, the name of the astronomical object can be resolved using either NED or SIMBAD.

Some fields, like observation date, can take ranges as input. Users can obtain help on a particular field by ‘‘clicking’’ on the link above that field. A **[Help]** link for the whole search page is also available. Archival researchers interested in finding MAST observations of a particular class of sources can use the **Object Category** field. This is more specific than the ‘‘Target Description’’ field available for HST observations and provides a detailed target classification. Its reliability depends on the mission but is normally relatively high. Only for IUE, in fact, the object class was provided by the Guest Observer, while for EUVE and the three ASTRO missions (UIT, HUT, and WUPPE) the categories were chosen by the project (for Copernicus data the classification was done at STScI based on the IUE classes).

Previewing and Retrieving Data

Retrieval of non-HST MAST data is simpler and faster than for HST data. No registration is in fact necessary (no username and password are required) and retrievals of most data require only to ‘‘click’’ on the file or target names (without going through ST-DADS). The following description applies to most MAST data.

The typical MAST search page returns a list of datasets matching the query submitted by the user. (The default is 100 records but this can be changed by using the **[Maximum number of hits]** button on the search page.)

The list includes various target parameters namely target name, coordinates, exposure time, etc. The user might want to have a ‘‘quick look’’ at the data before retrieving them. Previews are available for most missions and can usually be accessed directly by ‘‘clicking’’ on the object name. The **|More info|** column provides links to other pages to obtain additional information on the target. Namely, the **[NED]** link searches NED, which provides basic data and references for extragalactic sources, while links to other MAST missions start a search for the same target in these archives.

Retrievals can be initiated by marking the datasets of interest and then submitting the request (this is the default MAST retrieval procedure). In most cases this will result in the data files to be saved to the directory of choice on the user's computer[1]. Datasets may be downloaded as .tar, .tar.gz, .tar.Z, or .zip files. For some missions, files can be retrieved by simply ‘‘clicking’’ on

1. For a subset of IUE data (and for a limited time) the retrieval request will submit an e-mail to the NASA's National Space Science Data Center (NSSDC), located at Goddard Space Flight Center, where the request will be processed by the NASA Data Archive and Distribution Service (NDADS). Once the files have been retrieved an e-mail message will be sent to the user, who will be able to retrieve them via FTP. Ultimately all MAST data will reside at STScI and will be retrieved with a simple ‘‘click’’.

the file names (or on the EVT or IMG links for EUVE). Retrievals for all missions will be handled in the same way when all MAST data will be ingested in the MAST juke-boxes (and will all then be physically stored at MAST).

DSS and FIRST represent two somewhat different cases. The DSS interface returns a FITS file of the specified area of the sky (or around a specified astronomical source) the user is interested in. This can be displayed directly (if the browser is configured appropriately) or saved to disk. Similarly, the FIRST (**[Retrieve Image Cutouts]**) interface returns a radio image centered around a specified region of the sky (if covered by the FIRST survey). The source catalog can also be accessed from the FIRST WWW page (**[Search the FIRST Catalog]**) and provides detailed information on source parameters (positions, fluxes, size, etc.).

Cross-Correlations

The cross-correlation interface described above for HST currently also allows users to cross-correlate an Active Galactic Nuclei (AGN) catalog, a galaxy cluster catalog, and two star catalogs, plus any user-supplied list of positions, with the MAST archives. Individual missions (and HST instruments), each with a different correlation radius, can be selected. This is meant to facilitate archive searches for specific classes of sources spanning a given range of parameters. Multiple missions can also be selected, with the option to show only those sources that cross-correlate with *every* selected mission. For example, the user might be interested in finding all AGN that have been observed both with HST and IUE, or to find AGN observed with either HST or IUE.

We are planning to expand the choice of catalogs available for cross-correlation and thereby increase further the utility of this interface.

Prepared Data Sets

The MAST archive also contains (or points to) a number of ‘‘highly processed’’ data sets, which are typically spectra or grayscales (and in the future perhaps images) calibrated to a degree not permitted by routine pipeline processing. For example, the GHRS atlases include both lab and measured wavelengths of visible lines. These data have been published by various authors and have been made available generally both in the form of plots and ASCII data. They may be downloaded by simply ‘‘clicking’’ on corresponding links.

4 StarView Tutorials

In This Chapter...

StarView is one of the two user interfaces to the Hubble Space Telescope data archive (the other one being the WWW interface). Using StarView, you can:

- Browse the contents of the archive.
- Select observations that interest you.
- Preview public data.
- Retrieve data from the archive for scientific analysis.
- Select and retrieve calibration files to recalibrate HST data.
- Get information about planned but not yet executed observations.

StarView is fairly intuitive so many users find they can navigate the program using only the online help (use the **[Strategy]** button on any screen or the pull down **|Help|** menu in the menu bar). But we know you prefer reading informative and entertaining manuals over straining your eyes trying to make out tiny text on-line help screens. That knowledge gives documentation writers courage to carry on.

STScI used to maintain an archive host computer from which one could run StarView by logging in as a guest. For security reasons this service has been discontinued. As a consequence, StarView is now available in only one form, a distributed X-windows version running on the user's local system that sends requests for data to the server at STScI.

If you have any questions or problems using the archive, contact the HST archive hotseat via e-mail, `archive@stsci.edu`, or phone (410) 338-4547.

In this Chapter we present two tutorials designed to guide you through StarView and its principle uses. These tutorials include:

- A complete StarView session, including selecting observations and retrieving data.
- A description of commonly-used screens.
- A tutorial on selecting and retrieving calibration reference files.

Tutorial: Running Starview

In this section, a whole StarView session is presented. A second tutorial on selecting and retrieving calibration reference files is provided on page 51.

If Distributed StarView is installed on your system, and you are running X-windows, you should be able to start StarView by typing the command:

```
xstarview &
```

Running out of space during StarView searches? When running StarView you should make sure to set the StarView data directory to a disk with plenty of space prior to starting up StarView. StarView requires lots of scratch space for the file .svdata. If this space fills or is very near quota, the file can be truncated and cause StarView to act oddly: give segmentation errors and more rarely, flaky StarView screens. The default location of .svdata is your home directory. For Unix systems, include the following line in your .cshrc file, with a directory name (be sure to include the closing slash!):

```
setenv SV_DATA_DIR /myplace/bigdisk/name/
```

In VMS, put the appropriate version of this line into your login.com file:

$ DEFINE SV_DATA_DIR DISK$SCRATCH:[JOE]

Welcome Screen

The StarView <Welcome> screen (Figure 4.3) will appear. Upon start-up, messages in a little status screen say the system is “Loading the SQL query generator...”, etc. When the initial load is complete, the Welcome screen appears. If there is any urgent archive news (e.g., a message about possible system downtime), it will appear at the top of the welcome text. While the loading takes place, any input from your terminal keyboard will be ignored.

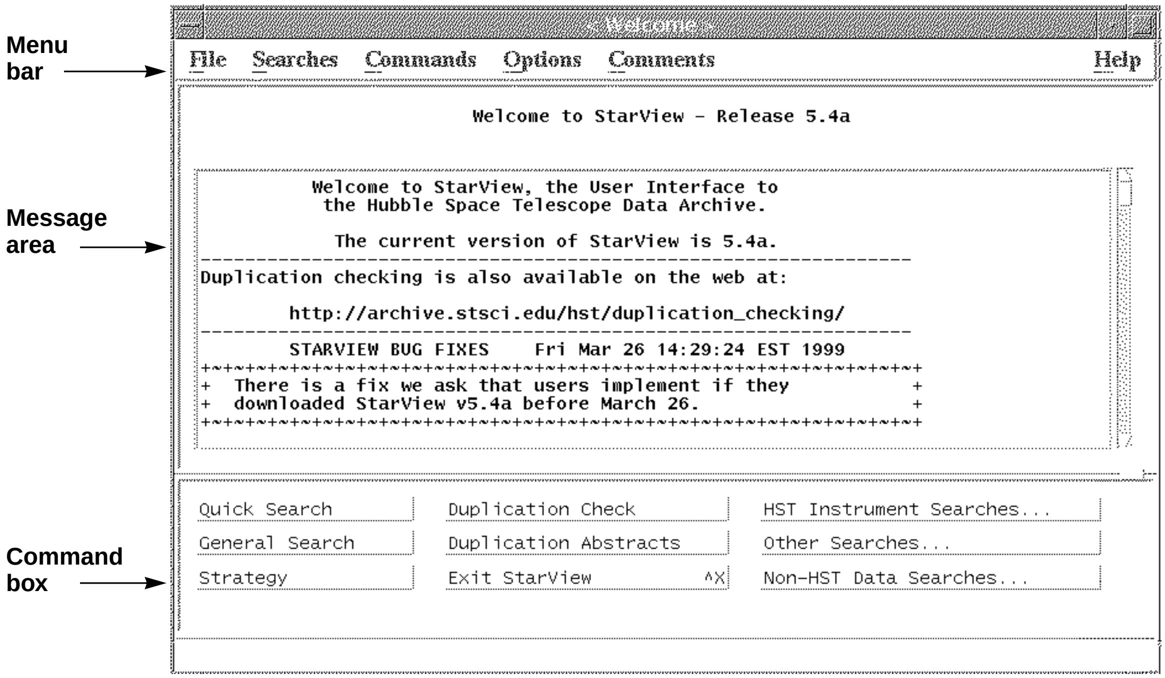

Figure 4.3: Welcome Screen

You can scroll through the text and read any additional information below the display area by using the scroll bar on the X-windows version of StarView.

Command Usage and Screen Interaction

- Use the mouse to select all functions.
- Choose options by positioning the mouse pointer over the command button or menu and pressing the left mouse button.
- Use keyboard shortcuts (listed on the menus) for faster performance.

Searching the Catalog

To search the catalog:

1. Choose a search screen.
2. Specify your search criteria, such as position and a release date before today's date so that you get public data.
3. Start the search by clicking on the **[Begin Search]** button.
4. Step or scan through all observations matching your criteria.

In this example we use the <Quick Search> screen to search the HST catalog.

The <Quick Search> screen is useful for most basic searches of the HST catalog. An extensive set of more detailed search screens is also available. To choose one of these, click on **[Other Searches]** or pull down the **|Searches|** menu from the menu bar. Figure 4.4 shows the <Other Searches> screen.

The Quick Search Screen

Choose the <Quick Search> screen by clicking the **[Quick Search]** button. Clicking in StarView is done by moving the cursor to the command button and pressing the left mouse button. The <Quick Search> screen is shown in Figure 4.5. We will use this screen to search for WFPC2 images of galaxy clusters.

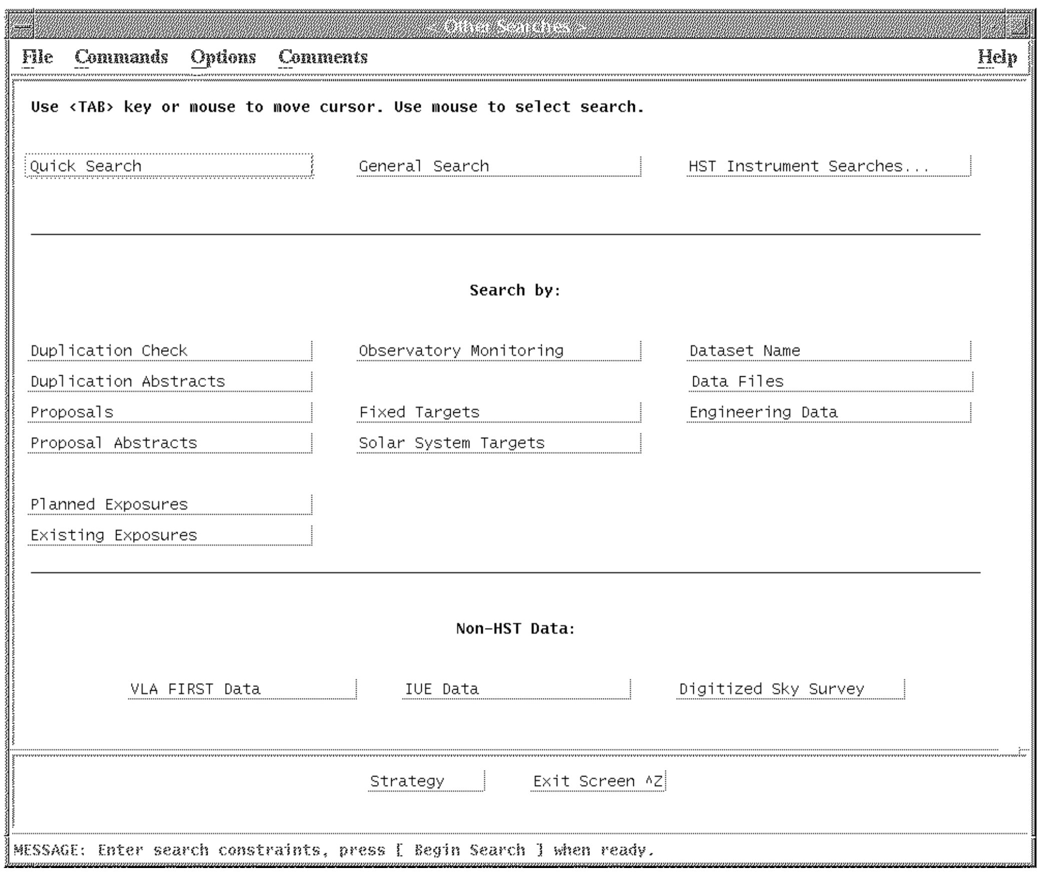

Figure 4.4: Other Searches Screen

Other Screens

All StarView screens can be accessed from the “Searches” pull-down menu or directly from the Welcome screen by clicking the **[Other Searches]** button. A subset of those screens is listed below:

- The <General> screen provides an expanded set of fields beyond those found in the <Quick Search> screen, including the filters and apertures used, exposure start time, and proposal type.
- The <HST Instrument Searches> screen provides access to the various instrument specific screens, which include reference, calibration, association, and On-The-Fly Calibration (OTFC) screens.
- The <Planned Exposures> screen can be used to check on the schedule dates and completion status of an HST proposal or to search for planned HST observations for a given target. This screen looks at tables made from the proposal entry and scheduling database at STScI.
- The <Proposal Abstracts> screen allows you to search on proposal-specific information, such as proposal title and keywords.
- The <Engineering Data> screen provides information on ephemeris data, engineering and engineering subset data, as well as mission schedules and mission time lines.
- The <Duplication Checking> and <Duplication Abstracts> screens are views of the complete lists of observations and potential observations. For checking conflicts or GTO plans, observers should use these screens (or the WWW interface at `http://archive.stsci.edu/cgi-bin/duplication`.)
- The <Digitized Sky Survey> screen, brought up from a button on the Other Searches screen, can access and retrieve images of the digitized Schmidt survey plates (Palomar Observatory Sky Survey in the north and the SERC Southern Sky Survey in the south) as stored on a collection of 102 CD-ROM disks in a jukebox. This screen also has a Preview facility with an option to overlay the HST field of view. The user specifies the FOV orientation angle and configuration (pre-launch or post-COSTAR).
- The <FIRST VLA> screen can be used to obtain VLA B-configuration, 20 cm images from a sky survey centered on the North Galactic Cap.

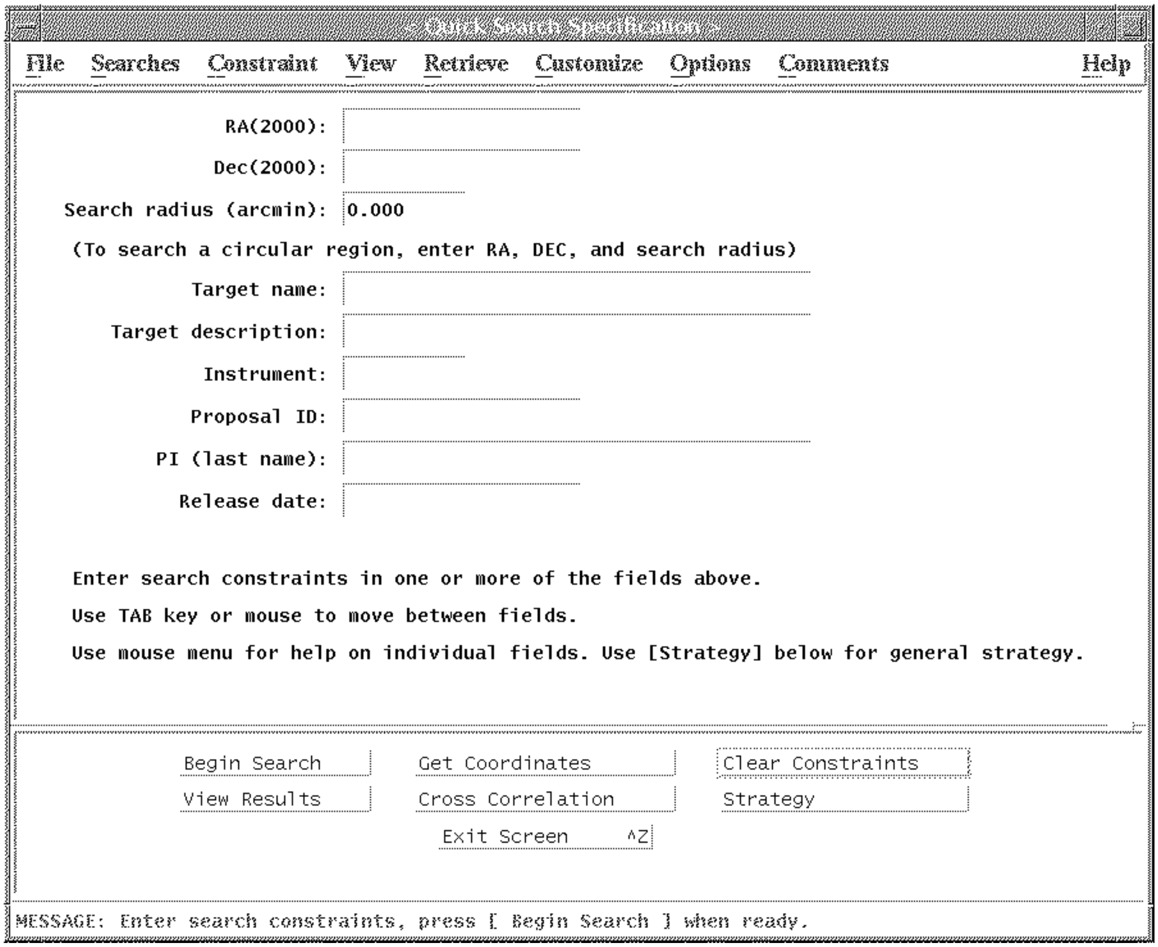

Figure 4.5: Quick Search Screen

Specifying Search Criteria

There are various ways to search for observations of a particular target in the catalog. The most reliable way to find a solar system target is to enter the name embedded in *qualifiers*, or wildcard characters, (e.g., *MARS*) in the target field.

The most reliable way to find fixed targets is by position. Because observers do not necessarily use the same convention to name sources, searching by name often will not return all observations of a given source. To be certain you retrieve *all* observations of a given stationary targets, search for observations within a given radial distance of your source's position by entering constraints in the RA, Dec, and search radius fields on the <Quick Search> Screen. Cross correlation is useful when you have an ASCII textfile, with a list of object coordinates in J2000 epoch, one object per line. For example, a file of the coordinates of the central galaxies in all Abell galaxy clusters with z>0.1 could be obtained by using NED (the NASA/IPAC Extragalactic Database) and with minor modifications, the same list could be used by StarView to search the archives. Consult the on-line help on cross-correlation for the proper format of the coordinate list.

If you do not know the RA and Dec of your target, you can click on the **[Get Coordinates]** button to connect to the SIMBAD or NED coordinate resolver from within StarView. The name resolver automatically determines the target's position. It then populates the RA and Dec fields on the search screen. If you are generally interested in extragalactic objects, you may wish to set the **[Get Coordinates]** button so that it connects to NED rather than SIMBAD. To change the name resolver from SIMBAD to NED, use the **|Options|** menu. To save your preferences from session to session, invoke **|Save Options|** from the Options menu.

Another way to search is by target description or class, as we do in the following example. Here we will search for all WFPC2 observations of galaxy clusters.

To find the STScI convention for a particular class, pull down the "Help" menu from the top right corner of the screen and look at the "Targets" entry. There you will find that the proper target description is "cluster of galaxies". Because an observer may have added other information to the description (redshift, for example) we use wildcard characters before and after the pattern of characters for which we are searching. In this particular example, over 5000 entries will be found. Be sure that your SV_DATA_DIR has adequate room for the storing the temporary disk records StarView creates during a session. (See page 30 for more information.)

We want WFPC2 observations, so click on the "Instrument" field and type "WFPC2". Other valid entries for the "Instrument" field are:

- Fine Guidance Sensors (FGS).
- Faint Object Camera (FOC).
- Faint Object Spectrograph (FOS).
- Goddard High Resolution Spectrograph (HRS).
- High Speed Photometer (HSP).
- Wide Field/Planetary Camera (WFPC).
- Wide Field Planetary Camera 2 (WFPC2)
- Near Infrared Camera (NICMOS).
- Space Telescope Imaging Spectrograph (STIS).

If you had wanted images from either WF/PC or WFPC2, you would type `wfpc,wfpc2`—StarView interprets the commas to be "or".

If you want to find only publicly-available data, you would constrain the "Release Date" field, for example, by typing `<1-MAY-1999` to find only data sets released before May 1, 1999.

Figure 4.6 shows how the <Quick Search> screen looks at this point.

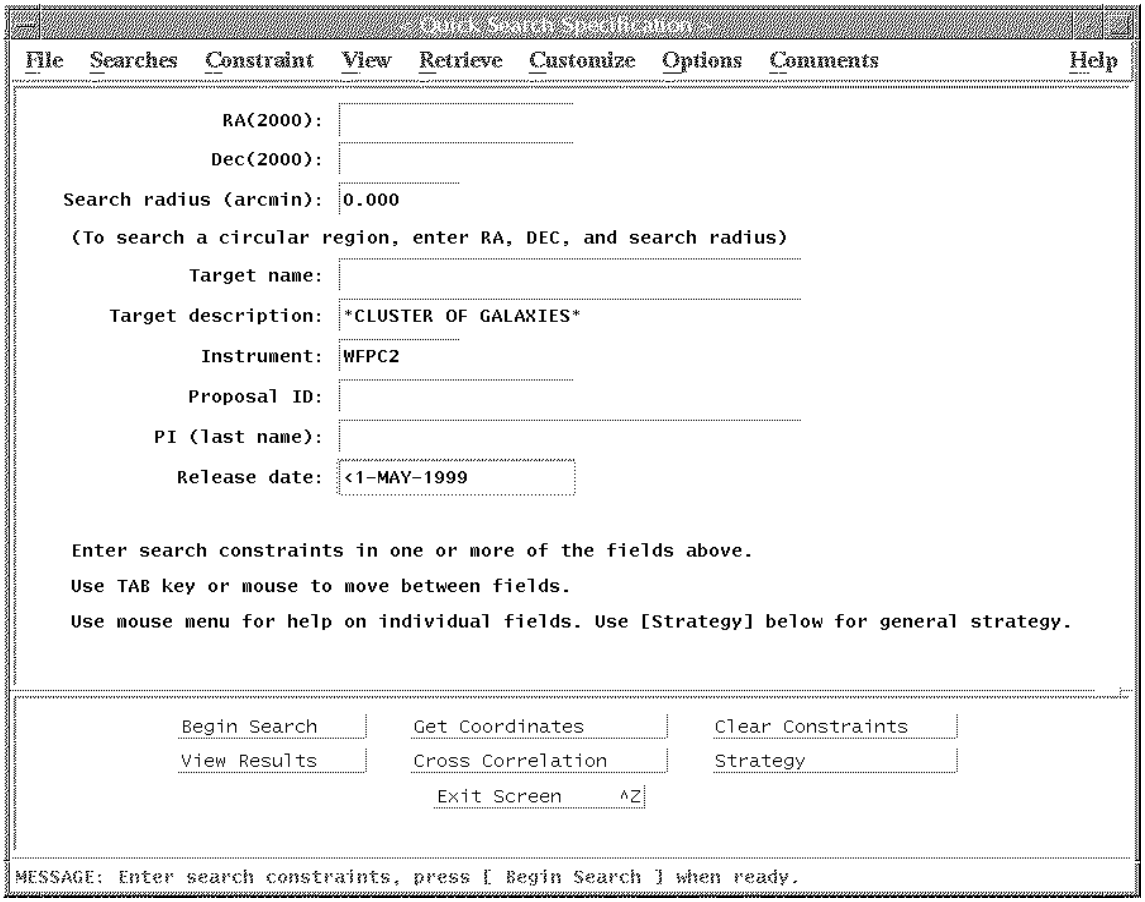

Figure 4.6: Quick Search Screen With Constraints Entered

A complete list of relational operators is provided in Table 4.1 (relational operators are the qualifiers for constraining a search). Some of these operators apply only to certain fields.

To determine which operators can be used in a given field, move the mouse over the field and press the right mouse button. A pop-up window provides information about the field, including a list of valid operators.

Operator	Function
=	Equal to
!=	Not equal to
>	Greater than
>=	Greater than or equal to
<	Less than
<=	Less than or equal to
..	Range
, (comma)	List
*	Wild card
!	NOT
&	AND
;	AND
|	OR
,	OR

Table 4.1: Relational Operators for Constraining Searches

Some Allowed Date Formats[a]
Jan 2 1999
2 Jan 1999
1/2/99
1-2-99
1.2.1999

a. Do not use commas in dates. StarView treats commas as an OR operator.

Table 4.2: A Subset of Allowed Date Formats in StarView

Text Searches

Text searches of abstracts, titles, and other text-based contents in the database can be useful. Usually one should embed words in the wildcard symbol '*', e.g., "*MARS*." Operators such as an OR (comma or a vertical bar), an AND (a semicolon or an ampersand), and a NOT (an exclamation point) can be used in simple Boolean searches. If the NOT or AND operator is used, all strings are automatically wildcarded. The former is useful for excluding targets like "BIAS" or "FLAT" from the results. StarView text searches are not case sensitive.

Getting help in StarView

Use the **[Strategy]** button to get information about using any StarView screen, or use the pull down **|Help|** in the menu bar to see all the available StarView help. To get help on the valid ranges for any field, use the *field help*. That is, move the cursor to the field and press the right mouse button (or press the Help button of your keyboard).

Starting the Search

Click on the **[Begin Search]** button to search the catalog for the observations satisfying your search criteria. If none are found, a message will appear at the bottom of the screen, and you will need to enter different search constraints. If at least one observation is found, the screen will change to the <Quick Search Results> screen. The <Quick Search Results> screen (Figure 4.7) shows the results of your catalog search. The first record that matches your search criteria will be displayed.

Viewing Found Observations

If you want to scan the full list of your search results:

- Click the **[Step Forward]** button to view one record at a time.
- Click **[Scan Forward]** to see all of the found records in rapid succession. Press any key to stop the scan. By scanning forward to the end, you physically complete your query. Depending on your search criteria, you could find a large number of records.
- To go back to previous records, use **[Step Back]** or **[Scan Back]** buttons.

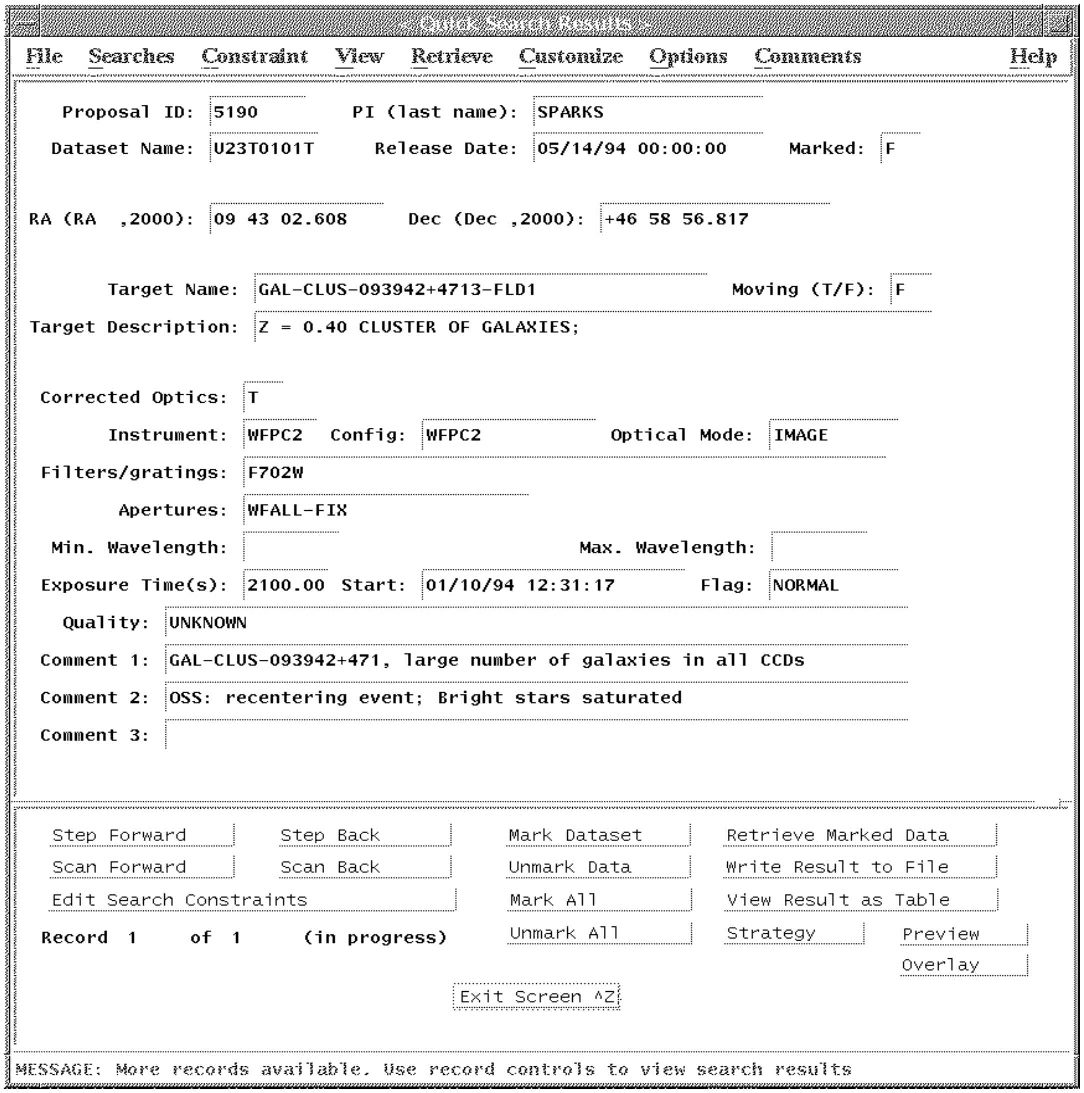

Figure 4.7: Quick Search Results Screen With Record Display

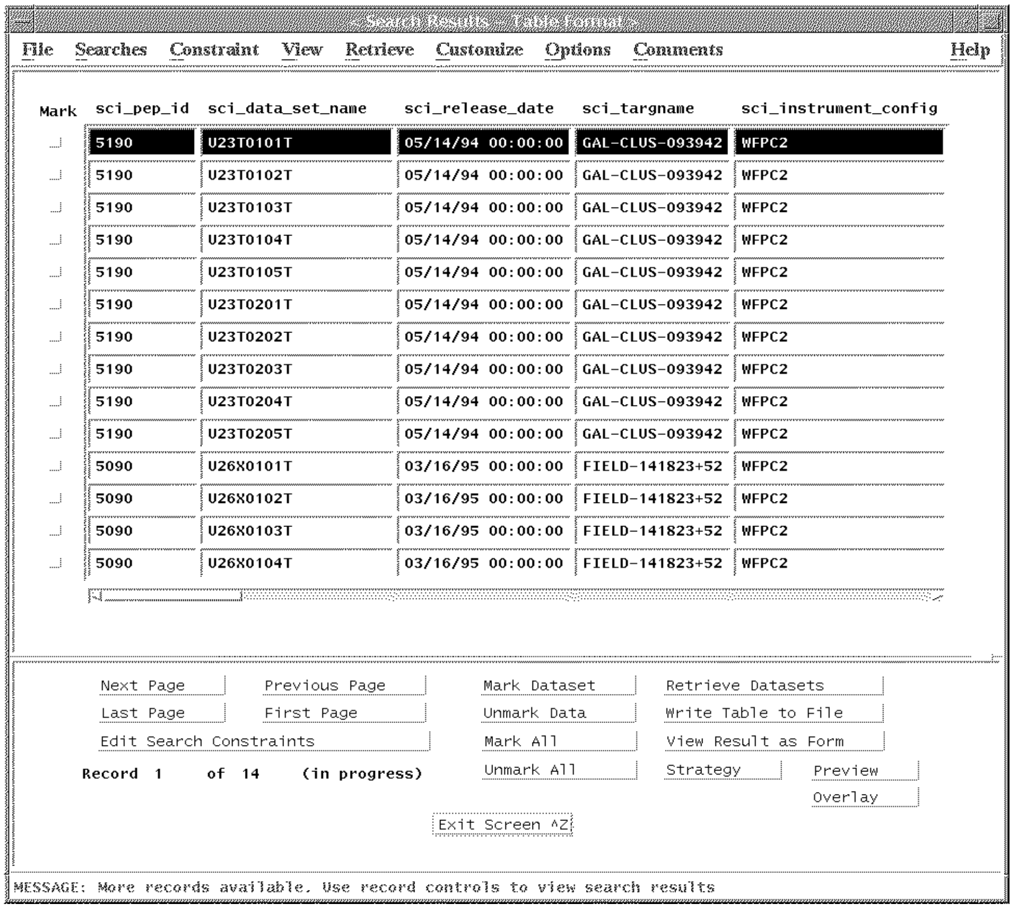
View your completed search results in a table with StarView's <Table Format> screen. Press **[Scan Forward]** to complete the query. Click **[View Result as Table]** to see a page of catalog records at the same time (see Figure 4.8). Select**[View Result as Form]** to return to the single-record screen format.



Mark	sci_pep_id	sci_data_set_name	sci_release_date	sci_targname	sci_instrument_config
	5190	U23T0101T	05/14/94 00:00:00	GAL-CLUS-093942	WFPC2

Figure 4.8: Quick Search Results Displayed on the Table Format Screen

Preview

The **[Preview]** button brings up a quick look at the data. Preview displays compressed HST images (not suitable for science analysis), as well as spectra. Most public data are available with previews[1]. Figure 4.9 shows an example of two datasets—one from a spectrograph, the other from the WFPC2 camera—viewed with the **[Preview]** command; spectra and images are displayed differently, so the figure shows both an FOS spectrum and a WFPC2 image. Images are displayed using SAOimage. Spectra are plotted using ACE/gr. These programs are publicly available and included in the distributed version of StarView .

1. The Canadian Astronomy Data Center is responsible for the production of data previews.

Previewing spectral data (sample is FOS data)

Previewing image data (sample is WFPC2 data)

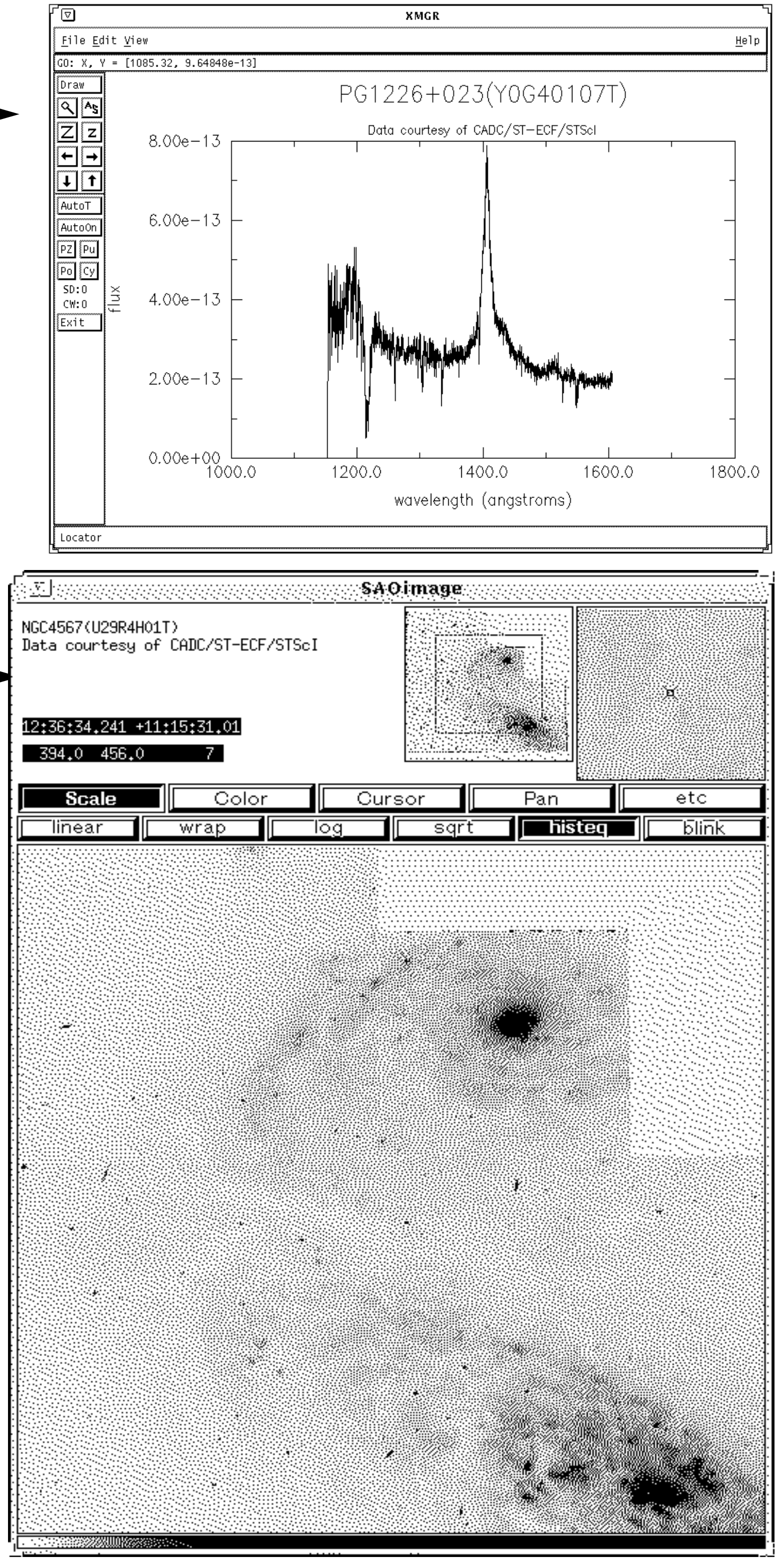

Figure 4.9: Previewing a Dataset

SAOimage will display the full intensity range of the previewed image, which in the case of WFPC/2 images includes substantial numbers of high intensity cosmic ray hits. To see low surface brightness features, you may find a log or sqrt scaling useful. For more information see the SAOimage help.

Saving Search Results to a File

You can save the values of any fields on the screen to an ASCII text file. To save a tabular version of results to a file:

1. Press **[Scan Forward]** to make sure that the query is complete.
2. Click on the **[View Result as Table]** button to see a table of all the cataloged records. The tables are usually larger than the screen. You can use the vertical and horizontal scrollbars to view the entire table.
3. Customize your output file in two ways:

A.••Click on the **[Write Table to File]** button. This will display the <Table Export> screen, shown in Figure 4.10. By clicking on **[Select Output Columns]**, you can write out data from selected fields only (Figure 4.11) with their *default widths*. This option has the advantage that you can save the attribute list, and retrieve that list rather than individually select the columns every time you make a table.

B.••Alternatively, clicking the *right mouse button* on a table column brings up a pull-down menu to delete or resize the column. The *middle mouse button* is used for reordering columns by clicking on the label of the column to be moved, dragging it to the desired column position (staying in the label area), and releasing it. When done, select **[Write Table to File]**. When the <Table Export> screen appears, do NOT click on **[Select Output Columns]** or you will remove all restrictions and settings you inserted with the mouse commands!

3. Check the optional settings, then click **[OK]**.
4. Specify the name of the file in which results are to be stored on the File Selector screen (Figure 4.12).
5. Click **[OK]**.

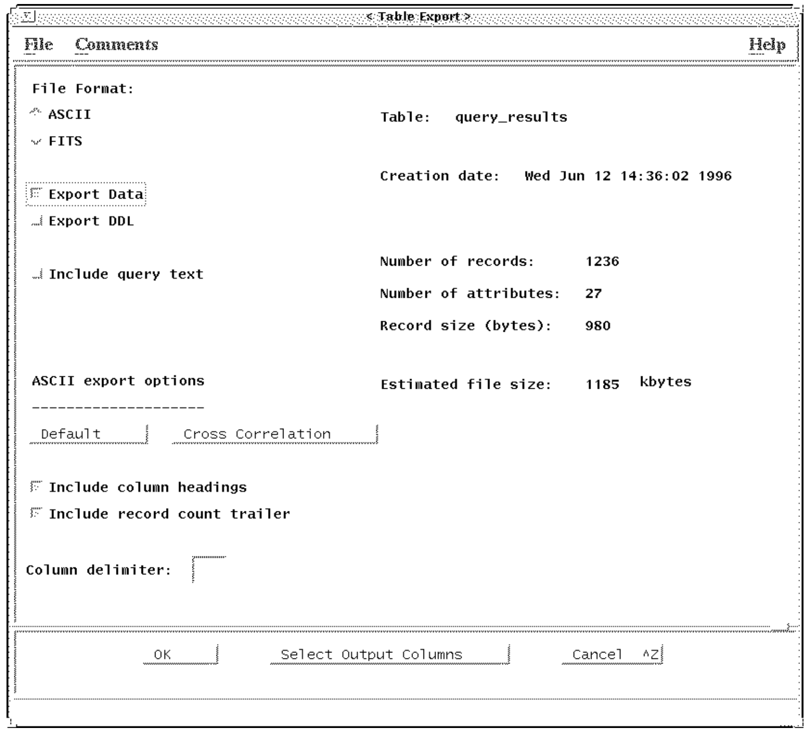

Figure 4.10: Options on Table Export Screen

In the <Table Export Attribute Selection> screen (Figure 4.11), you can select only a few fields to be saved to your output table. To select a field, click on its name; the attribute will be moved from the "Available Attributes" column to the "Selected Attributes" column. For example, you may want to see only the target name, position, dataset name, and operating mode. You can save and retrieve your table column preferences in an attribute file.

WARNING: Do NOT press the button **[Select Output Columns]** if you have already selected and resized columns in the <Search Results - Table Format> screen, because doing so will wipe out your careful work.

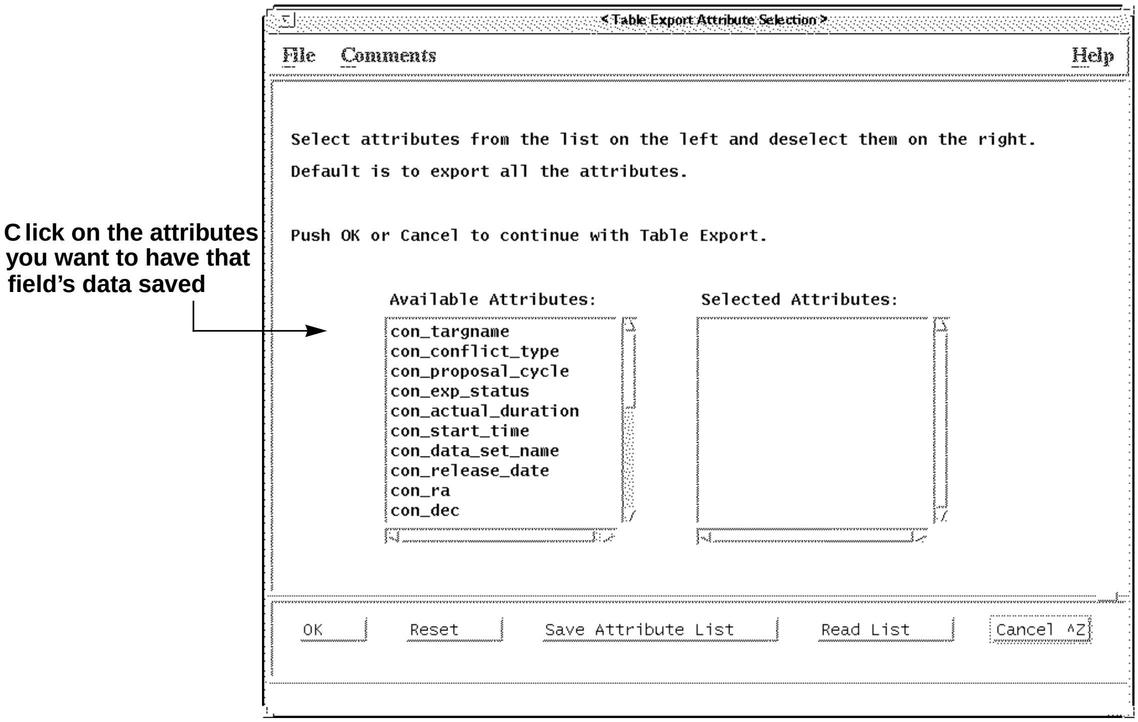

Figure 4.11: Selecting Attributes (Fields)

The File Selector screen shows the names of all files and directories matching the template given on the "Filter" line. To change directories, alter the "Filter" line and then click the **[Filter]** button. To change the name of the file to be saved, edit the "Selection" line.

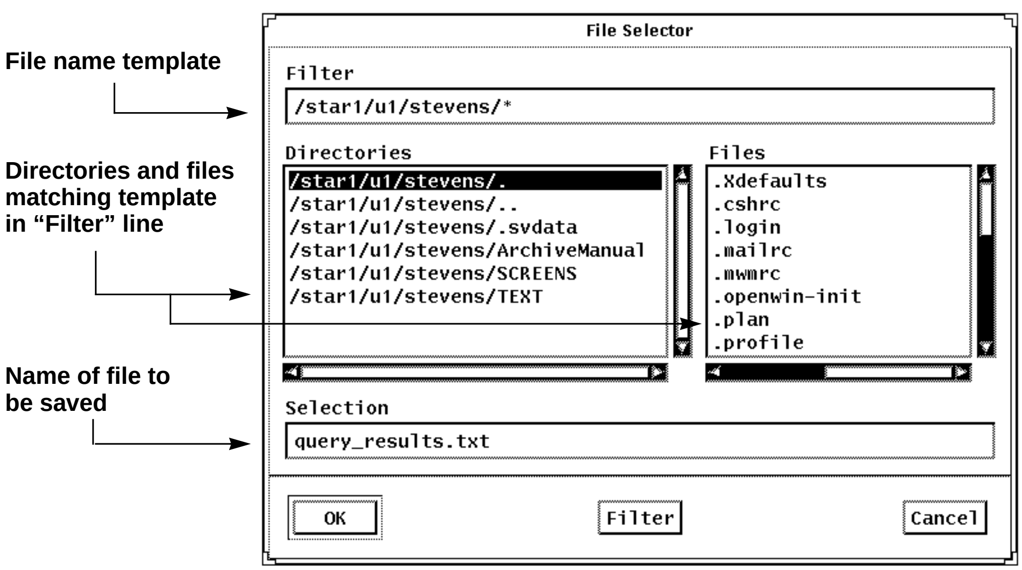

Figure 4.12: Specifying a Filename and Directory

Retrieving Datasets From the Archive

We now want to retrieve the datasets (see Chapter 9, Table 9.1 for how datasets are defined) that the catalog has identified. To do this, you will mark the data for retrieval and then do the retrieval. There are several steps in this process:

1. Mark the observations that you want to retrieve; you can mark them either individually or as a group.
2. Display and review the list of datasets to be retrieved.
3. Specify the file formats and media to be used in the retrieval process.
4. Submit the request. DADS will send you e-mail when the request is accepted for processing. (See “Getting Your Data” on page 11).
5. Check the request status, if desired. (You must wait until you receive the e-mail from DADS before checking a request.)

If you do not have an archive account, then you will not be able to retrieve data until you have registered with STScI. For information about how to register, see page 10.

Marking Observations for Retrieval

To mark for retrieval the dataset displayed on the screen, click the **[Mark Dataset]** button. This action will be confirmed by a message at the bottom of the screen. Also, the “Marked” field, in the upper right corner of the screen, will display “T” (True) indicating that the dataset has been marked for retrieval.

You can mark datasets for retrieval in either the table-row format display screen, in which case the highlighted record is marked, or on the <Quick Search Results> screen with the record displayed.

If you want to mark for retrieval *all* of the records matching your search criteria, click on the **[Mark All]** button. This could be a large volume of data. As of May 1, 1999, the complete set of datasets found for “clusters of galaxies” total 5,030 WFPC2 images, about 130 GBytes of data! Alternatively, step through your search results records by clicking on the **[Step Forward]** button and only click on the **[Mark Dataset]** button for a few of the observations.

Reviewing the Retrieval Request

Once you have marked records for retrieval, you begin the retrieval process by displaying and reviewing a list of datasets to be retrieved. To do this:

1. Click on the **[Retrieve Marked Data]** button to exit the <Quick Search Results> screen and to begin the retrieval process by bringing up the <Archive Retrieval> screen.
2. Review the list of datasets.

The <Archive Retrieval> screen lists all of the datasets that you have marked for retrieval. In this case, you would see something like Figure 4.13.

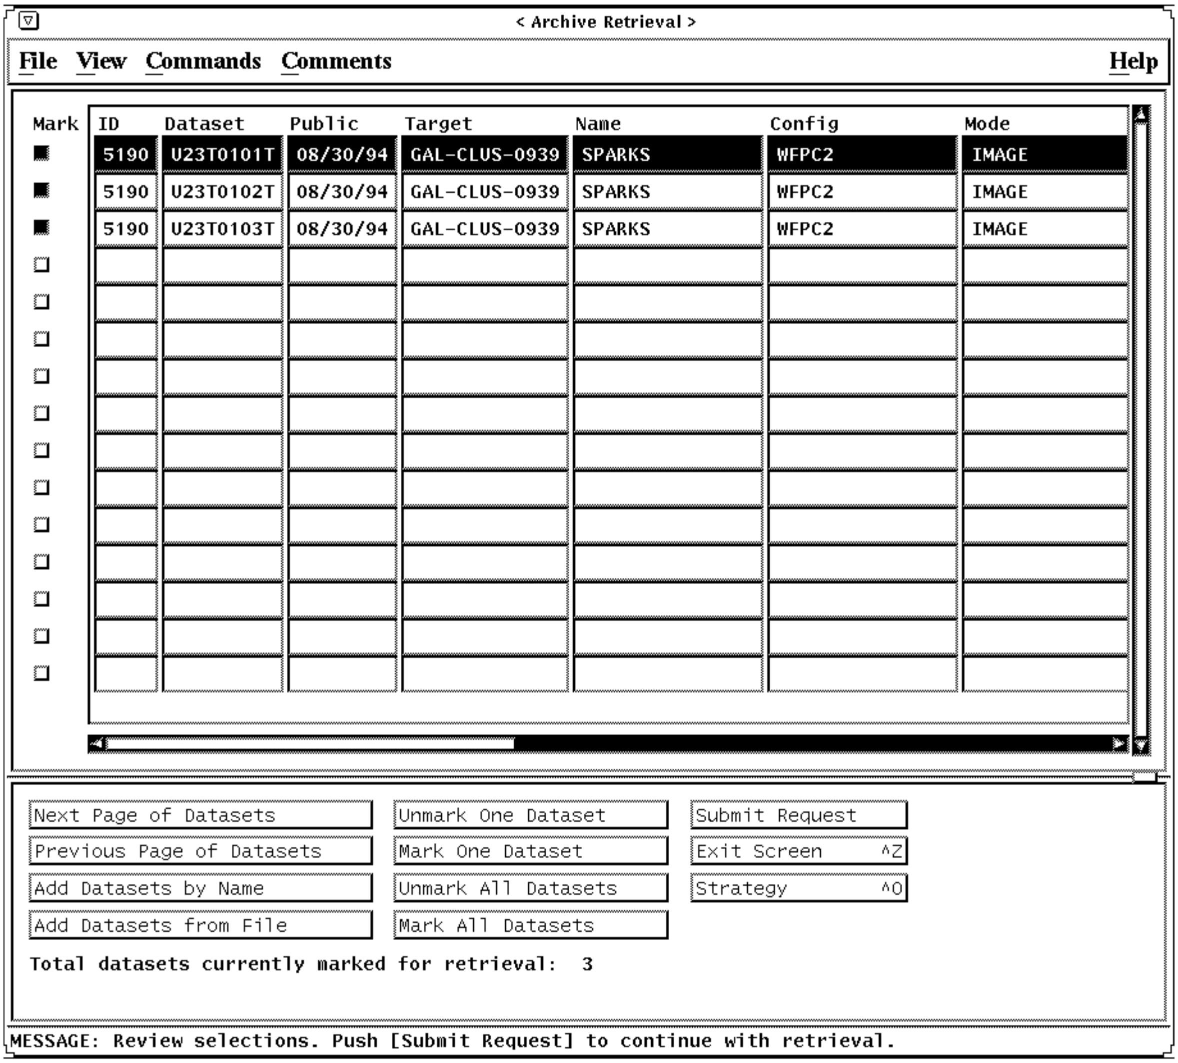

Figure 4.13: Archive Retrieval Screen (with 3 Datasets Selected)

Review the list of datasets that you have marked for retrieval. If you have marked several datasets, you may need to click on the **[Next Page of Datasets]** button to see additional screens of marked records. The total number of datasets that you have marked for retrieval is shown near the bottom of the screen.

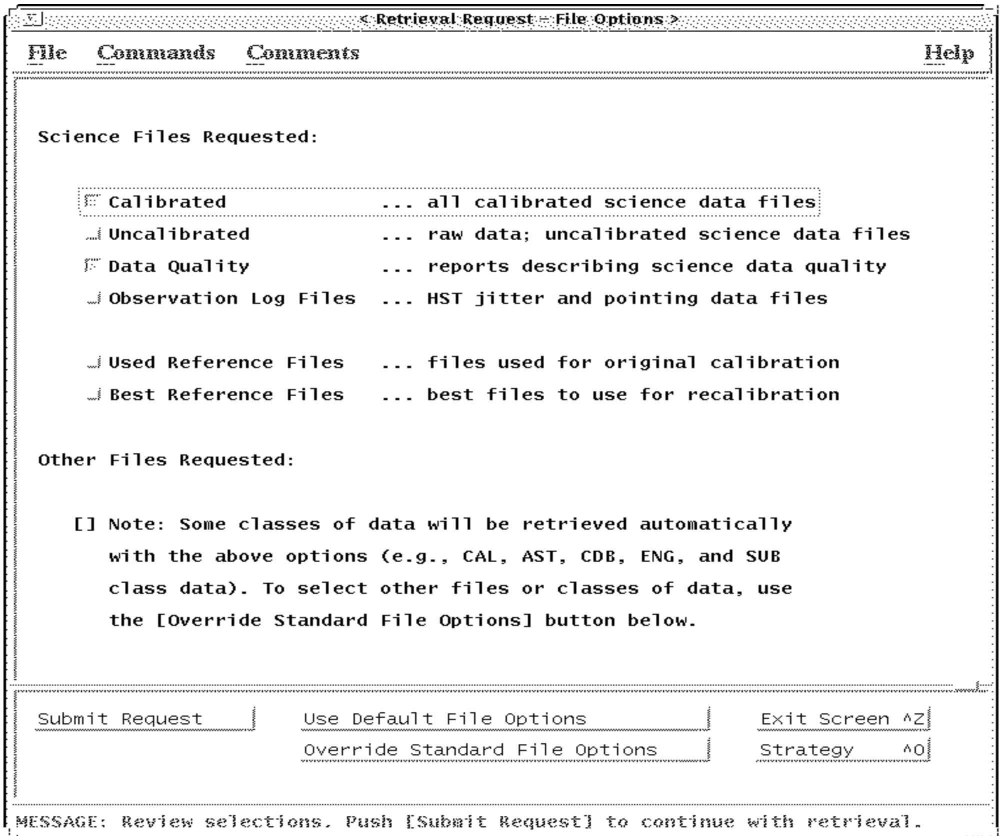

Figure 4.14: Retrieval Request - File Options Screen

Specifying Formats and Media

1. Continue with the data retrieval process by clicking the **[Submit Request]** button.
2. Specify the files that you want to retrieve.
3. When you click the **[Submit Request]** button, the <Retrieval Request - File Options> screen is displayed (Figure 4.14).

The <Retrieval Request - File Options> screen[2] indicates the kinds of files that will be retrieved, in this case the calibrated science data files and the data quality report files will be retrieved. These defaults are acceptable.[3] Click the **[Submit Request]** button to continue with the retrieval process. To help you determine the amount of data that you are requesting, Table 4.3 lists typical file and dataset sizes for calibrated data from each instrument.

---

2. With the external release of On-The-Fly Calibration (OTFC), the <Retrieval Request - File Options> screen will be as described on page 186.

---

3. You can override the defaults and provide your own file extension selection by using the **[Override Standard File Options]** button.

You may also request the calibration files that were used for the original calibration (the archived version in most cases) or the currently recommended “best-ref” calibration files for the most recent versions of the calibrations. The calibration files can be used to calibrate uncalibrated data with standard STSDAS tasks.

Instrument	Mode/File	CAL Class Size
FOC	normal 512 x 512	~4 MB
	zoom 1024 x 512	8–10 MB
FOS	normal	<500 KB
	rapid readout	>10 MB
GHRS	normal	< 500 KB
	rapid readout	>10 MB
HSP	normal	~500 KB
	occasional	>1 GB
NICMOS	CAL file	~ 1 MB
	IMA file	~ 0.75 MB/readout
STIS	CCD/MAMA image	> 10 MB
	CCD/MAMA spectrum	> 14 MB
WFPC, WFPC2	normal (full mode)	26 MB
	area mode	7 MB

Table 4.3: Average Calibrated Data File Size per Instrument

The <Retrieval Request - Media Options> screen is then displayed (Figure 4.15). You will need to enter your archive user name and password, pressing Return after each entry.

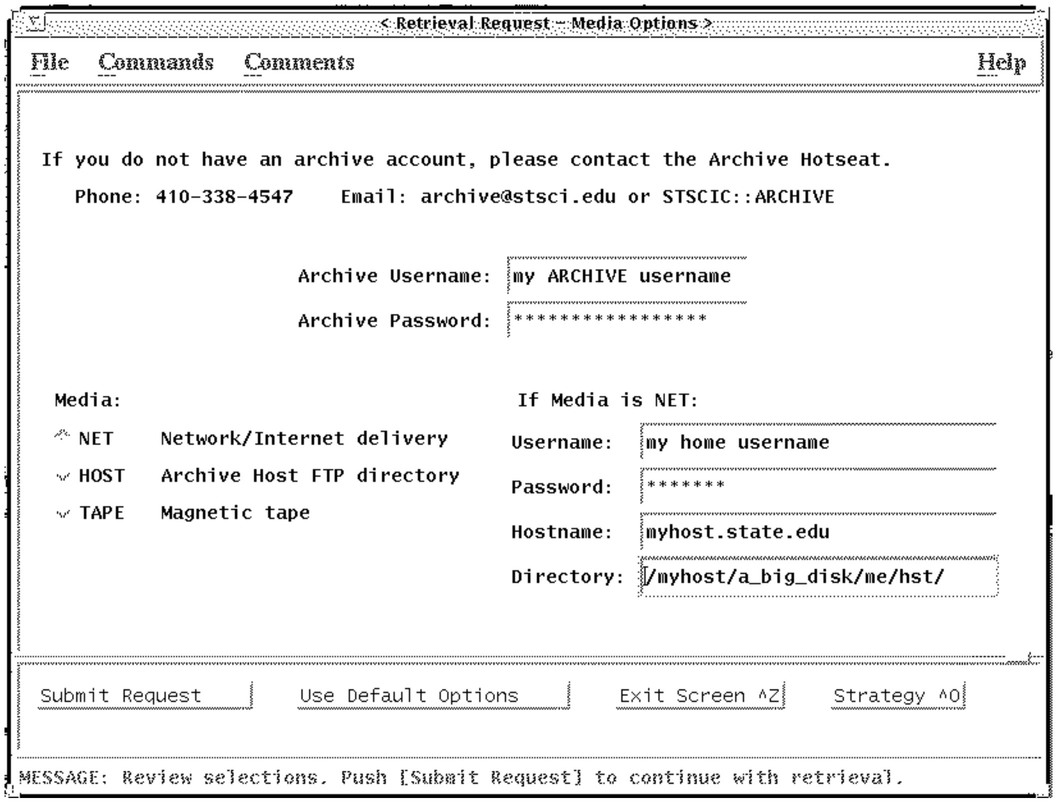

Figure 4.15: Retrieval Request- Media Options Screen

You may need to select the media option (the default will be NET). When HOST is the retrieval media, the data will be placed on the archive host staging area from which you can retrieve using FTP. You can also select the TAPE option. In this case, an 8mm tape will be mailed to you. Selection of the NET option (Network/Internet delivery) will require you to enter your home username, password, full host name (including your workstation name, e.g. nemesis.stsci.edu) and the full pathname of the directory where you want to receive the data. Make sure that you have room in this disk or the retrieval will fail.

After you select the appropriate options, click the **[Submit Request]** button to begin the data retrieval process. StarView will check to make sure that your archive username and password are correct and will then submit your request. A copy of the request file will be placed in the directory `.svdata` (as specified in the environment variable SV_DATA_DIR) on Unix systems or `[$HOME.svdata]` on VMS systems, where `$HOME` is your home directory. The file name is of the form *date_time*.req, for example, `940901_122510.req` is a file created on September 1, 1994 at 12:25 pm.

Checking Request Status

To check the status of your retrieval request do this:

1. Click on the **[Retrieval Status]** button from within the **|Retrieve|** menu on most StarView search screens, or click on the **|Commands|** menu from the <Welcome> screen.
2. You will be asked to enter your request ID (as displayed in the previous steps). Type the request ID.
3. Press [Return] to continue with your StarView session. Figure 4.16 shows a sample retrieval status screen.

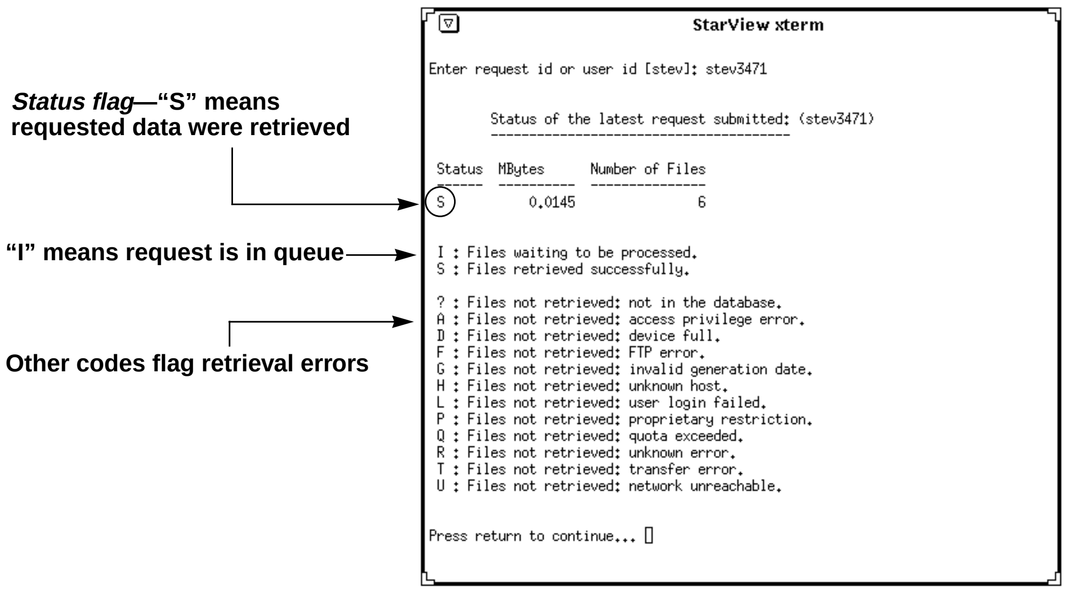

Figure 4.16: Sample Retrieval Status Screen

Note that until you receive e-mail from ST-DADS saying that your request is queued, the <Retrieval Status> screen contains no information about the status of your request.

Exiting StarView

Press [Control]-[X] to exit StarView. A dialog box will appear asking you to confirm that you really want to exit. Click on **[OK]** to exit.

Completion Notification

DADS will notify you by e-mail when it has finished processing your request. The notification will tell you the final status of your retrieval and the location of your data on the archive host's staging disk if you specified a HOST retrieval.

Getting Your Data

If you chose to have your files written to a disk on the archive host systems (the HOST option), you will need to log in using FTP and copy the files to your local machine. A directory containing your files will have been created; this directory will be a subdirectory of the `data` directory. Figure 4.17 shows an FTP session (you can ftp to either archive.stsci.edu or stdatu.stsci.edu, because they are the same machine.)

Connect to archive host using anonymous ftp

Figure 4.17: Retrieving Files Using FTP

You are now ready to begin analyzing your dataset. Remember, if you have any problems or questions, contact the archive hotseat at `archive@stsci.edu`, or phone (410) 338-4547.

Tutorial: Retrieving Calibration Reference Files

Often, archive researchers would like to re-calibrate their HST data. For several of the instruments, improved calibrations are possible with newer calibration files. See the HST Data Handbook for more information about processing the data. You can retrieve the calibration files necessary to calibrate the raw data via several means: simultaneously request them with the raw data, find and request them via the instrument screens, and request them by dataset name.

Note that with the external release of On-The-Fly Calibration (see page 135) the user will have the option of retrieving data calibrated ‘‘on the fly’’ with the best available reference files, at least for STIS and WFPC-2 data. The OTFC screens are described on page 187 (STIS) and 188 (WFPC-2).

Retrieving Calibration Files Simultaneously with the Science Files

The easiest way to retrieve calibration files for archival data is to retrieve them at the same time you retrieve the raw, uncalibrated science data. All of the relevant calibration files can be downloaded in concert with the raw science data if you select the option “Best Reference Files” or “Used Reference Files”. See Figure 4.14: on page 47 for a figure of the screen.

Retrieving Calibration Files via the Calibration Reference Screens

StarView provides calibration reference file screens for each instrument. These screens let you see which calibration files and tables were used to calibrate a given dataset by the OPUS pipeline and which files and tables are currently recommended. You can mark either the used or the recommended reference files and tables for retrieval and retrieve them through StarView.

In this example, we use a StarView reference file screen to retrieve both the *used* and *recommended* calibration files for a 3C273 dataset.

1. Start StarView as described in “Tutorial: Running Starview” on page 30. This will bring up the <Welcome> screen (Figure 4.6).
2. Click the **[Other Searches]** button. (We want to find the appropriate search screen for calibration reference files.) The <Other Searches> screen will be displayed (Figure 4.4), with the cursor highlighting “Quick Search”.
3. Click the [**HST Instrument Searches**] button. The <HST Instrument Searches> will be displayed (Figure 4.18)[4].

---

4. With the external release of On-The-Fly Calibration (OTFC), the <HST Instrument Searches> screen will include two additional OTFC buttons, one for STIS, the other for WFPC-2.

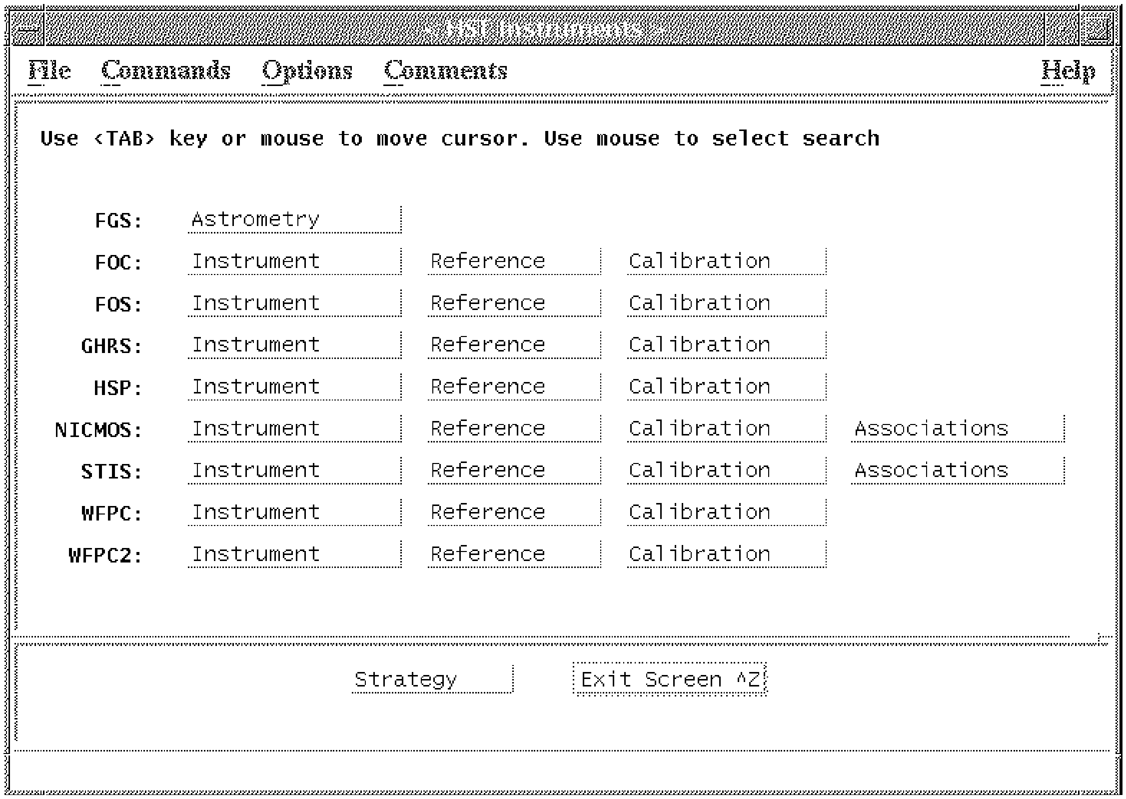

Figure 4.18: HST Instrument Searches Screen

4. Click on the WFPC [**Reference**] button because we will retrieve calibration files for a WF/PC observation. The <WFPC Reference Files - Search Specification> screen will be displayed. (Note that if you had just completed a search using another screen and had a list of datasets in front of you, the opening of this screen will close all other search screens, along with their results!)

5. Specify criteria. We want to specify a particular dataset, so press the arrow keys until the cursor moves to the “Dataset Name” field, and then type the dataset name for the observation whose calibration files will be retrieved. For example, enter `W19C0101T` (see Figure 4.19).

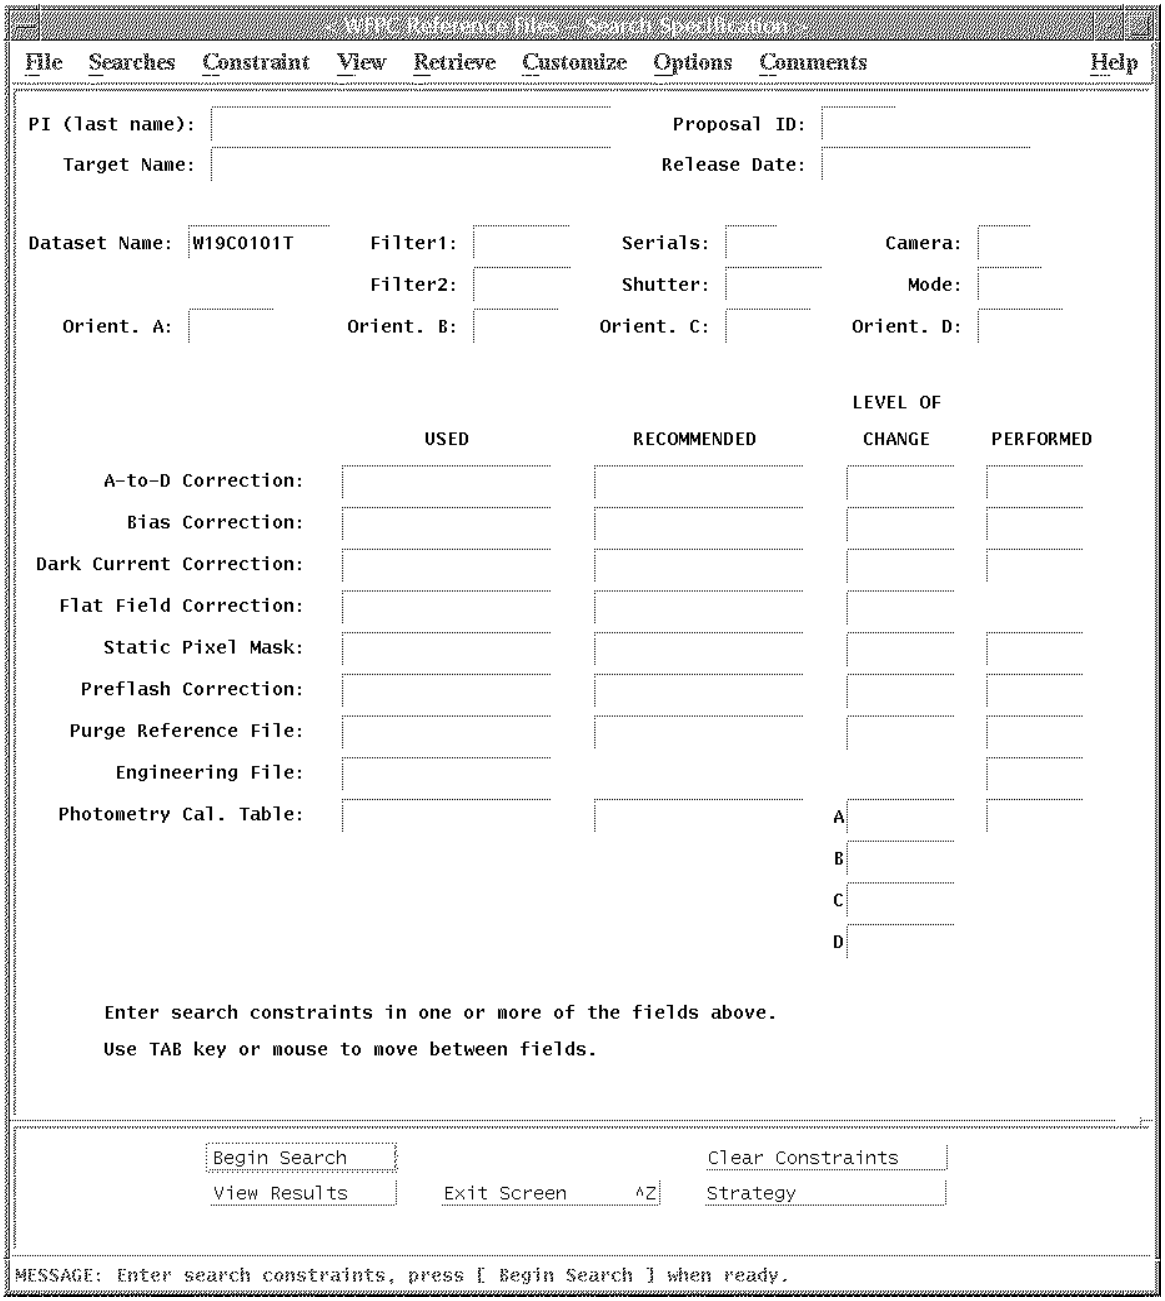

Figure 4.19: WFPC Reference Files - Search Specification Screen (Constrained)

6. Click on the **[Begin Search]** button to submit your catalog search request. The <WFPC Reference Files - Search Results> screen will be displayed for the observation that you specified (Figure 4.20). This screen will contain a scrollable view of the list of calibration sets for each dataset.

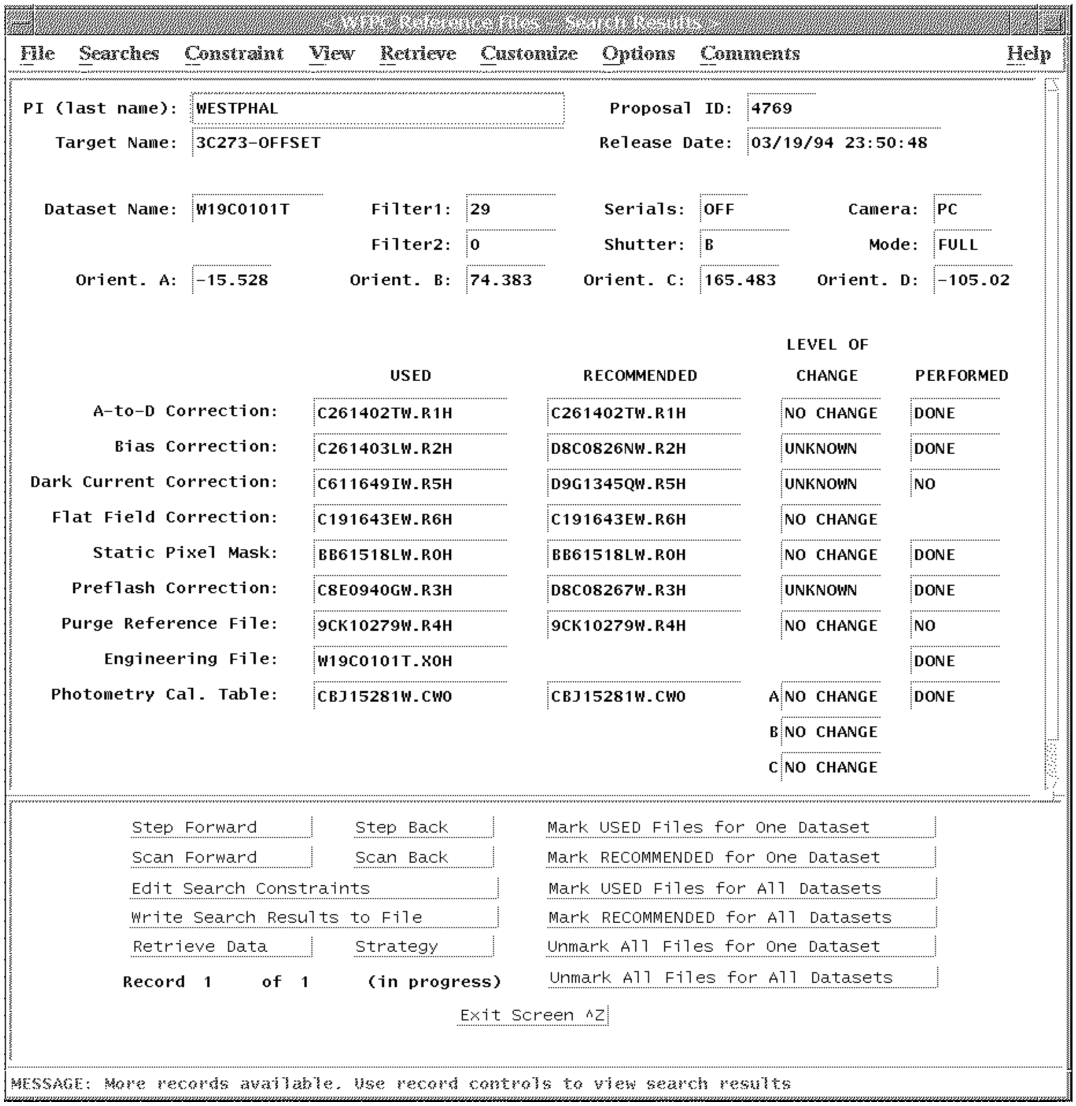

Figure 4.20: WFPC Reference Files - Search Results Screen (With Results Displayed)

7. Click **[Mark USED Files for One Dataset]** to mark for retrieval those calibration files actually used to calibrate the dataset. If the files listed in the RECOMMENDED column differ from those in the USED column, then you can click on **[Mark RECOMMENDED for One Dataset]** to retrieve the calibration files that are now recommended for calibrating the data.

8. Click the **[Retrieve Data]** button to begin the retrieval process for the marked reference files. Continue with the data retrieval procedures as outlined in “Retrieving Datasets From the Archive” on page 45.

The defaults on the <Retrieval Request-File Option> screen, i.e., calibrated, will return the correct files for the specified calibration reference files and tables. You do not need to specify an extension.

Retrieving a File By Name

If you already know the name of a file or dataset that you wish to retrieve from the archives, you can retrieve it directly using the **[Add Datasets by Name]** button from the <Archive Retrieval> screen. To get to this screen from the <Welcome> screen, pull down the **|Commands|** menu in the menu bar (see Figure 4.3) and choose the “Retrieve Marked Datasets” option. This will place you in the <Archive Retrieval> screen.

Click on the **[Add Datasets by Name]** button from the <Archive Retrieval> screen (or use **[Add Datasets from File]** if you have a list of dataset names). Enter the rootname (*no extension*) of the calibration reference file or science file you wish to retrieve. When you have added all the rootnames for the files you wish to retrieve, click on **[Submit Request]** and proceed with the retrieval process as described on page 45.

Another way of retrieving individual datasets is to use the <Dataset Name Search Specification> screen (see page 190).

5 Archive Search Strategies with StarView

In This Chapter...

This chapter describes the type of information that you can find on StarView screens and offers some approaches that you can use to find information and datasets in the Hubble Space Telescope (HST) Archive. Refer to Chapter 8 for a complete presentation of the available StarView screens.

Choosing the Right StarView Screen

StarView includes many predefined screens with which to query the HST catalog. StarView screens are organized in groups that provide a particular type of information. Each screen was designed to facilitate a certain kind of inquiry, spanning a range of customers from engineers and instrument scientists to general observers. These screens do not list the only kinds of searches that can be done on the archive. Advanced users may wish to construct customized queries. The archive hotseat will accept suggestions for modifications to current screens or suggestions for new ones. Below, a brief outline of the different screen groupings and a brief description of their contents are presented. A description of the <Quick Search> screen is also provided here, since this screen will typically be the starting point for most archival searches. Refer also to Chapter 8 for a more in-depth description of each screen.

The following screens and screen groupings are described below:

- <Quick Search> screen
- Planned observation screens (information on planned exposures)
- Science data screens (primarily containing exposure-level information)
- Instrument screens
- Association screens
- Calibration (reference file) screens
- On-The-Fly Calibration screens
- Archived files and engineering and timeline screens
- Data Files screens
- Observatory Monitoring Screens

The descriptions below should help you plan your catalog search strategy and in determining which StarView screens you should use to obtain the catalog information that you seek.

<Quick Search> Screen

The <Quick Search> screen is the most basic search screen for archival research. It is usually the best screen for a new user to begin with when searching for archival data. This screen provides you with a view of both exposure-level and proposal-level information in the HST catalog. You can use the <Quick Search> screen to search for HST observations at a given position in the sky (using the "RA" and "Dec" fields), in a particular region of the sky (using the "RA," "Dec," and "Search radius" fields), for a specific target (using the "Target name" field), or for a given type of source (using the "Target description" field). You can also use the <Quick Search> screen to search for observations taken with a given instrument or with particular proprietary release dates.

After a search request has been submitted from this screen, the <Quick Search Results> screen is displayed. The <Quick Search Results> screen provides additional exposure-level information, such as the archived dataset name, the exposure start time and duration, detailed instrument parameters (e.g., optical configuration, operating mode, filters, gratings, and apertures), the moving target flag, the exposure flag, and the Post Observation Data Processing System (PODPS, now known as OPUS[1]) Data

1. In order to streamline operations and software development, OSS (Observing Support Systems) and PODPS (Post Observation Data Processing System) were merged into OPUS (OSS/PODPS Unified System) on December 5, 1995.

Quality (PDQ) comments (see page 75). You can use this information to judge the usefulness of the exposure for a given line of research. See also “Assessing Data Quality” on page 74.

The date on which the dataset became or will become public (i.e., available for archival research) is also displayed on the <Quick Search> screen in the “Release date” field.

<General Search> Screen

The <General Search> screen is similar to the <Quick Search> screen, except it includes more exposure- and instrument-specific parameters. Using the <General Search> screen requires more familiarity on the part of the user with the Hubble Space Telescope and its data conventions. However, there are some searches which are quicker to do with the <General Search> screen than with the <Quick Search> screen. Searching by “Dataset name” is quicker than searching by “Instrument” because of the way the science table is indexed. If you know how the dataset names are coded for instrument, you can use the prefix plus the wildcard character * to constrain a query to search for only certain instrument outputs. (See Table 9.1 on page 215 for a list of conventions.)

Planned Observations

StarView contains a set of screens that provide users access to information about exposures and planned exposures. This information is derived from the Phase II proposals submitted for each program.

The <Planned Exposure>, screen provides users with information on future fixed target (non-solar system) exposures. This screen is updated with further information after exposures are completed; however, if you are only interested in images already taken, the <General Search> screen will usually prove more useful. The <Solar System> screen provides users with Phase II planning information on moving targets.

The <Proposal Abstract> screen contains the scientific abstract of the proposal and may provide insight into the planning of the observations. The abstract is now searchable as one, continuous text field. Use wildcards to embed all of your text searches; the commercial SQL software in use attempts to make perfect matches otherwise. The <Proposal> screen contains administrative information that is likely to be of interest mainly to STScI staff.

Science Data Screens

StarView provides a few screens that display a variety of exposure-level information about executed HST observations. The <Quick Search> screen (described above) is one of the screens in this group. The others are the

<General>, <Exposure Search>, and <Target Search Specification> screens.

StarView's exposure-level observation screens provide the main mechanism for learning about the actual executed parameters of each HST exposure. In addition to the searches described above for the <Quick Search> screen, you can use the observation screens to obtain specific information about various exposure parameters for HST observations, to search for observations that used a specific set of instrument parameters, to search for observations of specific targets or classes of targets, to search for observations within a specified range of proprietary release dates, or to obtain observation parameters for specific datasets. If you need to know some of the more particular instrument parameters for the exposures, you should use one of the specific instrument screens (described below).

You can use the <Exposure Search> screen not only to obtain the usual exposure parameters (e.g., target name and position, exposure start time and duration) for HST observations, but also to find the various Sun-Earth-Moon angles pertaining to the observations and to find the proposal line numbers and mission scheduling unit numbers corresponding to the displayed dataset records. Archival researchers can use these parameters to find scientifically complete sets of observations that were obtained at nearly the same time, often with essentially the same instrument setup.

Instrument Screens

StarView provides a set of screens that include more complete information about the instrumental parameters used in HST observations. There is one screen for each scientific instrument on the HST. Each such screen displays information specific to the exposures taken with that instrument, including the instrumental setup and readout parameters used for the observations.

You can use these screens to determine precise instrumental parameters for a preselected observation (e.g., readout format, wavelength ranges, preflash times, acquisition modes) or to search the HST catalog for all observations in the archive that have observing parameters similar to those used in the observations that you are specifically interested in analyzing. The latter is useful if you want to compare your data with similarly acquired data, or if you simply want to find out how many observations used similar instrument parameters. For example, you may want to determine if an instrument configuration was rarely or commonly used. Commonly used instrument configurations are probably better calibrated and better understood.

Association Screens

StarView provides a set of screens that allow the user to search the Archive for detailed information about the association status of NICMOS and STIS observations. For STIS and NICMOS, in fact, the combination of data from two or more exposures is often necessary to create a scientifically useful data product. Associations simplify the use of HST data by identifying a set of exposures that belong together and depend upon one another. By default, complete associations of data are retrieved via the <General> or <Quick Search> screens. The association screens, on the other hand, permit exposures to be retrieved individually rather than as a set of observations.

Calibration Screens

StarView provides a set of screens that let you identify and retrieve the calibration tables and files that are recommended to calibrate specific HST observations. There is one screen for each scientific instrument on the HST (except the FGS). Each such screen displays the calibration information specific to the exposures taken with that instrument. These screens will help you in determining whether a dataset needs to be recalibrated. In particular, you can use one of these screens to list, on a per-dataset basis, the files that were used to calibrate a given dataset (the USED list) and, at the same time, to list the files that are now considered to be the best files to use in calibrating that dataset (the RECOMMENDED list).

A dataset’s recommended calibration files may change if, in retrospect, a more appropriate file could have been used than the one which was originally used. Commonly, the best calibration data is taken contemporaneously with the science data, and has not been processed into calibration sets until several weeks after the science data has been archived. However, even if this is true, recalibration is not always necessary. Whether or not you recalibrate depends on which file or table was changed and whether that kind of correction is likely to affect your analysis. The *HST Data Handbook* explains the different calibration corrections and the files or tables that each type of correction uses (see page 14).

These screens are not necessary if you plan to retrieve the calibration reference files at the same time you retrieve the science data.

On-The-Fly Calibration Screens

The On-The-Fly Calibration (OTFC) system will allow users to retrieve the most recent version of calibrated HST data. OTFC screens go beyond the Calibration Screens described above and allow users to view which reference files will be used by the OTFC service and the settings of various switches that govern the calibration software to retrieve science data.

The OTFC service should be released externally to STScI by Fall 1999. The OTFC Pipeline accepts raw datasets from DADS and returns updated raw and calibrated datasets. OTFC updates the headers of the raw data files, then processes them through the current OPUS software. Users do not have to go through these screens to request OTFC service - that option will be available on the <Retrieval Request - File Options> screen. These screens allow the user a view into the OTFC process. Currently only WFPC-2 and STIS data will be processed in the OTFC pipeline. Eventually OTFC will be applied to NICMOS and future instruments data

Data Files Screens

StarView provides screens that display accounting information about the datasets and files stored on the optical disks that comprise the HST data archive. They include the <Dataset Name>, <Files>, and <Engineering> screens. In general, archival researchers should not need to access the any of these screens unless they want to know if a particular type of file has been created for a given dataset, want to retrieve a specific individual file for a given dataset, or need to determine the size of a given file. The <Engineering Timeline> screen searches for ephemeris data, engineering and engineering subset data as well as mission schedules and mission timelines. Typically, you will wish to find a specific type of data corresponding to a typical time period.

Observatory Monitoring Search

The Observatory Monitoring Search Screen facilitates searches based on telescope configuration, such as Roll Angle, Earth Limb Angle, and Sun Angle. It also allows queries on jitter limits. If you are interested in characterizing how an instrument behaved when the telescope was in certain angles, or if you would like to know the telescope alignment during a specific observation, this is the screen for you.

Search Strategies

Two frequent types of archival searches are:

- Searching for HST observations of a specific source (e.g, 30-Doradus or the jet of M87)
- Searching for observations of a given class of source (e.g, all observations of SNR or O stars)

Suggested strategies for carrying out such searches are described below.

Searching for Specific Sources

There are two ways to search for observations of a specific source:

- Search on positional coincidence
- Search on the basis of source name

The source or target name is generally an observer-entered designation. Therefore, for fixed targets, searches based on positional coincidence are much more reliable than searches based on source name. With the growing number of parallel observations with no specified targets, searching by coordinates is the only way to check for conflicts and duplications.

Positional Searches: The Best Way

There are three ways to search for positional coincidences with observations in the HST catalog using StarView. You can constrain the target RA and Dec, specifying a range of permissible values. This defines a search rectangle. You can also specify an RA, Dec, and search radius on either the <Quick Search> or <General> screen. You can also specify a common name for the target and let SIMBAD or NED provide the target position and search radius (see page 35).

Searching on Source Name

Most of the StarView screens have a field for the target name. In addition, the <Target Search Specification> screen contains both the target name and alternate names or aliases. The archival researcher can constrain and search on the basis of source name using these fields. When using the <Target Search Specification> screen to search for a given source name, you must perform two separate searches:

1. First, constrain the target name. Then, press **[Begin Search]**.
2. Next, clear the search constraints for target name and constrain only on the alias. Then, press **[Begin Search]** again.

When constraining, the source name should always be embedded in wild card delimiters (e.g., `*MARS*` or `*NGC1068*`) because the name will frequently be embedded in additional text (see below).

Since an astronomical source typically has many names, to understand how best to constrain the target name and alias fields, it is useful to know how target names and aliases are assigned. Target names are used to provide unique designations for targets within a given proposal. They are entered by the observer during Phase II of the proposal process. There are three different classes of targets—fixed targets, solar system targets, and generic targets. Observers are encouraged to use a specific convention when naming fixed and solar system targets.[2] The next three pages provide a brief summary of the

---

2. Refer to the *Phase II Proposal Instructions* (accessible from `http://www.stsci.edu/observing/observing.html)` for a detailed list of these conventions, including the conventions for naming uncataloged targets.

conventions for each class of target, which should help you design search strategies based on source name.

- **Fixed Targets**. When providing a target name for a fixed target, the observer must specify one catalog name that will become the target name (e.g., `HD124897`). The observer is encouraged to provide one or two common names that will become the target aliases (e.g., `ALPHA-BOO` or `ARCTURUS`). The preferred order for catalogs to be used to designate the target name is summarized in Table 5.1 below. Observers may also append a qualifier to the catalog name to indicate the location in the source where the observation is centered (e.g., `NGC4486-JET`, `LMC-R136A`, or `NGC224-004012+40548`, where the name of the parent body is followed by rounded J2000 coordinates). Finally, a code designating the target purpose must be appended to the target name when a target is observed specifically to be used as an external calibrator (`-CALIB`), as an astrometric reference star (`-REF`), or as an offset for target acquisition (`-OFFSET`). For example:

```
BD+284D4211-CALIB, 3C273-OFFSET
```

Object Type	**Preferred Catalog Order**
Stars	*Henry Draper Catalog* (e.g., `HD140283`) *Durchmusterung* (BD, CD, or CPD) (e.g., `BD+30D3639`) *General Catalog of Variable Stars* (e.g., `RR-LYR`)
Star Clusters and Nebulae	*New General Catalog* (e.g., `NGC6396`) *Index Catalog* (e.g., `IC418`) Perek-Kohoutek designation (e.g., `PK208+33D1`) Sharpless catalog number (e.g., `S106`)
Galaxies and Clusters of Galaxies	*New General Catalog* (e.g., `NGC4536`) *Index Catalog* (e.g., `IC724`) *Uppsala Catalog* (e.g., `UGC11810`) *Abell Catalog* (e.g., `ABELL2029`)
Quasars and Active Galaxies	See Veron-Cetty and Veron, *ESO Report No. 18*, 1998 (e.g., `3C273`)

Table 5.1: Preferred Catalogs for Object Classification

- For targets with common catalog names, it is usually best to use StarView's NED- or SIMBAD-assisted search feature (see page 35) to find all instances of that target in the HST catalog.

- **Solar System Targets**. The target name for solar system targets can either be chosen from the standard list of solar system targets reproduced in Table 5.2, or the observer can define a name. As with fixed targets, qualifiers can also be appended to the name (e.g., `MARS-FEATURE1`). Therefore, to find all observations of Mars, one must embed Mars in wild card delimiters: *MARS*.

- **Generic Targets.** Generic targets are usually given names by proposers that describe either the astronomical characteristics of the targets (e.g., SUPERNOVA or COMET) or the general location of the targets on the sky (e.g., HIGH-LATITUDE). Though observations of specific targets are the final outcome of such proposals, the proposed observations themselves do not include specific target names or specific target coordinates. Targets of Opportunity and Parallel target observations are typical examples of generic targets. It is therefore not generally useful to search for observations of generic targets in the HST catalog using specific target names. It is better to search for such targets either by using the target category or target description keywords (see the next section) or by searching for observations in an area of the sky that is likely to contain HST targets of interest to you (see "Search Strategies" on page 62).

Level 1 Objects	Level 2 Objects		
Sun	Moon	Adrastea (1979J1)	Janus (1980S1)
Mercury	Phobos	Thebe (1979J2)	Epimetheus (1980S3)
Venus	Deimos	Metis (1979J3)	Helene (1980S6)
Earth	Io	Thethys	Telesto (1980S13)
Mars	Europa	Dione	Calypso (1980S25)
Jupiter	Ganymede	Rhea	Pandora (1980S26)
Saturn	Callisto	Titan	Prometheus (1980S27)
Uranus	Amalthea	Hyperion	Atlas (1980S28)
Neptune	Himalia	Iapetus	Cordelia (1986U7)
Pluto	Elara	Phoebe	Ophelia (1986U8)
	Pasiphae	Ariel	Bianca (1986U9)
	Sinope	Umbriel	Cressidea (1986U3)
	Lysithea	Titania	Desdemona (1986U6)
	Carme	Oberon	Juliet (1986U2)
	Ananke	Miranda	Portia (1986U1)
	Leda	Triton	Rosalind (1986U4)
	Mimas	Nereid	Belinda (1986U5)
	Enceladus	Naiad	Puck (1985U1)
	Pan	Thalassa	Despina
	Charon	Galatea	Larissa
	Proteus		

Table 5.2: Solar System Target Names

Searching for a Class of Objects

Archival researchers may be interested in finding all (or most) HST observations of a given class of objects (e.g., observations of elliptical galaxies or Wolf Rayet stars). There are several ways to carry out such searches:

- Search on the target description.
- Search on proposal title, proposal keywords, or proposal abstract.

- Cross-correlate the contents of the HST catalog with a catalog or personally created list of sources on the basis of position. See "ASCII Catalogs" on page 79.

StarView may not execute text searches in the manner to which you may be accustomed in other text search algorithms. The fields, for example, the target description or the abstract, are saved in a database as one continuous text string, not word by word. In general, text searches for a single keyword should be embedded in wild card delimiters. A list of keywords, e.g. *STAR*,*CEPHEID*, should individually be embedded. This list is treated as STAR OR CEPHEID. If you would like a search to reveal abstracts where *both* those keywords appear, you would enter STAR & CEPHEID. Where the database is all capitals, StarView will automatically convert your input to upper case. Text searches are case insensitive.

Searching on Target Description

Searches can be done on descriptions entered by the original observers during the Phase II (planning) process. These fields allow an archival researcher to search for HST observations of classes of objects. The target description and target categories appear on the <Target Search Specification> screen. The target description is the target category with additional descriptive words appended, so the target category is somewhat redundant.

If you wanted to search for all observations of nova stars within our galaxy, one could use the <Target Search Specification> screen, constrain "Target category" as `star`, and constrain "Target description" as `*nova*`. Note the use of the wild card delimiters (*), since the word "nova" will likely be embedded in a longer text. Alternatively, since the target description in StarView is the Phase II target category plus the Phase II target description—in that order—one could simply use the <Quick Search> and <General Search> screens and constrain the "Target description" field to `*star*nova*` or `star & nova`.

The observer assigns the target description as part of the Phase II proposal process, using the guidelines in the *Phase II Proposal Instructions*.[3] Each target must be assigned a single primary category followed by at least one descriptive keyword. Observers are encouraged to use as many as five descriptive keywords per category and are allowed to assign up to two categories.

The categories and corresponding keywords that the observer can use to describe fixed targets are presented in Table 5.3 through Table 5.11. For solar system targets, the descriptive keyword convention is presented in Table 5.12. Obviously, searches based on target description will be most successful if archival researchers use the same terminology used by observers to describe

3. Although Cycle 0 and 1 observations were not initially described using this set of guidelines, target descriptions for all Cycle 0 and Cycle 1 GO and GTO observations were redefined in the HST catalog to comply with the most recent *Phase II Proposal Instructions*, ensuring that a consistent set of terms are used to describe the archived observations.

the targets. Keep in mind that assigning target descriptions is an inherently subjective process. There are many ways to describe the same target, and different observers will inevitably describe the same target in different ways. You may, therefore, want to apply broad criteria when first constraining a target description. If you are looking for a complete list of all HST observations of a given type of source, you are encouraged to search also on the proposal title, abstract, and abstract keywords and to cross-correlate positional lists of sources with the archive. Furthermore, parallel observations usually are not well described by such keywords.

In Table 5.3 through Table 5.11, information in parentheses next to the keyword is explanatory only and is not part of the catalog. For example,Table 5.4 has a keyword identified as “LMXB (Low Mass X-Ray Binary).” “LMXB” is the keyword that appears in the target descriptor. The text is explanatory only.

Category Keyword	Contents
STAR	Galactic stellar object
EXT-STAR	Star in an external galaxy
STELLAR-CLUSTER	Galactic star cluster, group, or association
EXT-CLUSTER	Star cluster in an external galaxy
GALAXY	Galaxy or AGN
CLUSTER OF GALAXIES	Galaxy groupings, clusters, or large-scale structure
ISM	Interstellar medium of the galaxy
EXT-MEDIUM	Interstellar medium of an external galaxy
UNIDENTIFIED	Unidentified object
CALIBRATION	Calibration observations

Table 5.3: Keyword Categories

Descriptive Keywords for Stars (STAR or EXT-STAR)			
Wolf Rayet (WC)	Wolf Rayet (WN)	Main Sequence O	Giant O
Supergiant O	OE	OF	SDO
WDO	BO-B2 V-IV	B3-B5 V-IV	B6-B9.5 V-IV
B0-B2 III-I	B3-B5 III-I	B6-B9.5 III-I	BE
BP	SDB	DB	DA

Discrete Features of Objects			
Corona	Ring	Ansae	Protoplanetary Disk
Wind	Accretion Disk	Jet	Lobe
Hotspot	Nucleus	Halo	Disk
Bulge	Polar Ring	Dust Lane	Spiral Arm
Shell	Tidal Tail	Bar	Multiple Nuclei
Cooling Flow	Emission Line Nebula	BLR (Broad Line Region)	NLR (Narrow Line Region)
Filament	Ejecta	Knot	Star Forming Region
Shock Front	Ionization Front	Conduction Front	Undesignated

Table 5.11: Discrete Features and Keyword Descriptors for All Categories

Keyword	Comments
PLANET	If observation is centered on planet, may be followed by planet name, e.g., PLANET JUPITER
SATELLITE	If observation is centered on object, may be followed by name of object, e.g., SATELLITE GANYMEDE
COMET	If object is centered on comet's nucleus, may be followed by name or catalog designation, e.g., COMET 1979X
ASTEROID	If target is asteroid center, may be followed by common name or catalog number, e.g., ASTEROID CERES
FEATURE	Surface features are followed by the name of the parent body, e.g., FEATURE IO
OFFSET	May be followed by name of parent body, e.g., OFFSET COMET HALLEY
RING	Will be followed by name of parent body, e.g., RING SATURN
TORUS	Will be followed by name of parent body, e.g., TORUS SATURN
OTHER	May be followed by description of observation type, e.g., ASTROMETRIC REFERENCE or ZODIACAL LIGHT

Table 5.12: Solar System Keywords

Searching on Proposal Title and Abstract

Besides searching for individual HST observations of a given source class based on the target description, you may want to search for HST observing proposals that concentrate on, or include, observations of a certain class of source. Refer to our text search strategy at the beginning of this section (page 66). The <Duplication Abstract> or <Proposal Abstract> screens contains a summary of information about each accepted proposal, including the proposal title and the keywords from the proposal abstract, as well as the proposal abstract itself. To find, for example, proposals for observations of Seyfert galaxies, constrain proposal title as `*seyfert*`. To expand the search to proposals that pertain to Seyfert galaxies, repeat the search, clearing constraints for proposal title, and constraining the abstract text as `*seyfert*`. Having identified and recorded specific proposal numbers of interest, you can then return to the <Quick Search> or <General> screens, list the relevant proposal numbers separated by commas, and bring up all observations that were taken for such proposals.

Assessing Data Quality

The quality of data in the HST Archive varies greatly. While it is difficult to assess the quality of the data in a given HST exposure from the keyword information alone (i.e., without actually obtaining and analyzing the data), there are several keywords that are written to the HST catalog and displayed by StarView screens that can help you to get a feel for the quality of the data in a given dataset. Among these are the following (each of which are described in the following sections):

- The PDQ keywords and comments
- The exposure flag (expflag)
- The fine guidance system lock used to track the target (fgslock)
- Previewing images
- Observation log files for data taken after October 20, 1994

When interpreting the relevance of these parameters for a given observation, bear in mind that the importance of these parameters to data quality is relative. It depends both on the characteristics of the source being observed and the purpose to which you will put the data.

In addition to the complete science data set, the archive contains compressed versions of all public data sets. These compressed versions can be viewed with StarView (and the WWW interface) and thus allow the user to gain an idea of the quality of an image or spectrum by direct inspection. A detailed discussion of the preview capability can be found in Chapters 3 (WWW interface) and 4 (StarView).

In addition to the above methods of assessing data quality, for data taken after October 20, 1994, you can also obtain observation logs for a given dataset. The observation log files contain detailed pointing information (including jitter information) as well as the information on the spacecraft position and attitude. This information is provided at high time resolution, and should be particularly useful in many cases for investigating problems that are revealed by an inspection of the data or data quality comments. The Observation Logs can be retrieved using Starview by first marking the science dataset in StarView (say on the <Quick Search > or <General Search> screens) and then selecting the "Observation Log Files" option on the archive retrieval screen.You can inspect some of this information with the <Observatory Monitoring Search> Screen.

Procedural Data Quality Keyword and Comments

Each science dataset is displayed and evaluated for data quality after it has been calibrated by OPUS. OPUS assigns a parameterized PDQ keyword to the dataset and writes an optional PDQ comment. The PDQ quality keyword and comments are written to the HST catalog and can be displayed in StarView using the <Quick Search> or <General> screen (which displays the PDQ comments). When you are interpreting the relevance of the PDQ keyword and comments, bear in mind that:

- Data quality parameterization is inherently subjective
- The relevance of the keyword and comments depends on the nature of the target of the observations

Care must be taken to combine a knowledge of the characteristics of the target with the PDQ keyword and comments when evaluating data quality. For example, while an evaluation of `no-source` for an observation where the target was a bright star and the integration time sufficient that a clear detection was expected may well indicate poor data quality, the same evaluation for an observation where the target was a distant, faint cluster of galaxies (for which co-adding of many exposures is required) indicates little about the quality of these data.

As described above, the PDQ evaluation is composed of a parameterized keyword and a comment. The comment describing the data is fully at the discretion of the operations astronomer. Table 5.13 lists possible values that the operators can assign to the parameterized PDQ keyword and a brief explanation of their meaning. This list of permissible keyword values was officially adopted as of February 1, 1992. Data processed prior to that date were described with a similar set of values. However, some of the original values were found not to be useful and were dropped from the current list, while other values were added. Most of the values on the list have been used since shortly after launch. Note that while several of the allowed values may apply to a given observation, the operator can assign only one value to the keyword for each observation. Also note that when data is reprocessed, it is not re-evaluated for data quality. So, some of the older, obsolete keyword values remain for some observations.

Keyword	Meaning
BADCHAN	Quality significantly compromised by dead CCD column(s) or bad diode(s)
COSRAY	Compromised by cosmic-ray contamination
DATA-DROP	More than about 2% missing, or data missing from probable area of interest
EDGEPSF	Got only an edge of the point-spread function
INCOMPLETE	Got only some of the expected data groups
NO-COUNTS	Zero-level data
NO-EVAL	Inadequate time or resources for data evaluation
NO-SOURCE	No sources visible in image
NOISY	High background, low signal-to-noise ratio
OK	No apparent problems
POOR	Other problems affecting probable scientific utility (used when no other keyword applies)
SATURATED	Target saturated; counts rolled over, etc.
TRAILED	Observation taken on gyros, trailed sources, but otherwise OK
UNDEREXP	Observation seems underexposed
UNKNOWN	Uncertain of usefulness or quality of data

Table 5.13: PDQ Keywords

The PDQ Files

The complete OPUS data quality report can be retrieved from the archive. Every PDQ file is archived as ancillary data (class ASA) with the same root name as the observation and an extension of `_pdq.fits`. In addition to the data quality keyword and comments, the complete PDQ file contains predicted as well as actual observation parameters extracted from the standard header and science header files. To obtain the PDQ files associated with particular datasets, be sure that the **[Data Quality]** button is selected on the <Retrieval Request - File Options> screen.

OPUS Observer Comment Files

Observer comment files may help an archive user determine the quality of an HST observation. OPUS also monitors the health of the telescope and provides observers with a real-time interface.

Observer comment files contain updated mission information obtained at the time the observation was executed. OPUS personnel put comments into this ASCII text file. However, these files are not created for every observation executed. The data quality files, like the PDQ files, can be retrieved using the **[Data Quality]** button on the <Retrieval Request - File Options> screen.

Exposure Flag

The exposure flag keyword (`expflag`) serves as a comment to the exposure time keyword (`exptime`). It indicates whether the exposure completed successfully, without interruption, and whether the actual exposure time was different from the predicted exposure time. Note here the difference between predicted exposure time and proposed exposure time. The proposed exposure time includes setup time, while the predicted exposure time is only the predicted on-source integration time. The exposure flag can be useful in that it allows the archival researcher to determine whether the integration time obtained for a given observation is equal to the integration time the original observer expected for that exposure. The details of how the value of this keyword is set are complex and instrument-dependent. Table 5.14 gives a generic description of the possible values of this keyword and their meaning.

Fine Guidance System Lock

The tracking mode requested for each HST observation is given in the keyword `fgslock`, which is displayed on the <Exposure Search> screen and on the different instrument screens. There are currently three tracking modes available during HST observations: coarse and fine lock, which use the FGS's, and gyro stabilization. When the HST is stabilized with gyros, no guide star acquisition occurs, and the absolute error of positioning is ±30". The anticipated guiding accuracies for the three modes are 0.002"/sec drift rate for gyro hold, 0.015" RMS jitter for coarse track, and 0.005" RMS jitter for fine lock. Obviously, the guiding accuracy required by the archival researcher in a given observation depends on the purposes for which the data are to be used. For the three different tracking modes, the values of the `fgslock` keyword are GYROS, COARSE, and FINE.

Keyword	Meaning
NORMAL	EXPTIME was successfully calculated from telemetry information, is equal to the predicted exposure time, and there is no indication that the exposure was interrupted. EXPFLAG is also set to `NORMAL` when EXPTIME was successfully calculated and the predicted exposure time was not available.
INTERRUPTED	EXPTIME was successfully calculated from telemetry information, is equal to the predicted exposure time, but there is an indication that the exposure was interrupted.
INCOMPLETE	EXPTIME was successfully calculated from telemetry information and is less than the predicted exposure time.
EXTENDED	EXPTIME was successfully calculated from telemetry information and is greater than the predicted exposure time.
UNCERTAIN	The Shutter Log Overflow flag was set, which indicates that not all shutter open and close times are available. EXPTIME was calculated from the shutter open and close times that are available.
INDETERMINATE	EXPTIME could not be successfully calculated from the telemetry, and the predicted exposure time was not available.
PREDICTED	EXPTIME could not be successfully calculated from the telemetry, and EXPTIME was set to the predicted exposure time.

Table 5.14: Exposure Flag Keyword Values

Observation Log Files

Observation log files for each science dataset taken after October 20, 1994 have been produced in the pipeline and written to the HST archive. The observation log files contain a specialized set of pointing and engineering data associated with each science exposure (including the jitter information). You can retrieve these log files using StarView via the <Observatory Monitoring Search> screen. You can also retrieve these files by first marking the science dataset in StarView (say on the <Quick Search> or <General Search> screens) and then selecting the observation log files option on the archive retrieval screen. Remember, that the observation log files are only available for those data taken after October 20, 1994.

ASCII Catalogs

To assist in searching the HST Archive and in preparing proposals, ASCII catalogs are available which list completed and planned proposals and exposures.

Proposals

One catalog is available that summarize proposals which have been submitted.

- The Proposal Abstracts Catalog lists abstracts from completed and planned proposals. It is sorted by proposal ID. (See the file `proposal_abstracts.cat`.)

Exposures

Two catalogs have been created which provide a summary of completed and planned exposures. For each catalog, there are separate files for the entire catalog, sorted by RA and Dec, and for solar system targets only, sorted by target name.

- The Planned and Archived Exposures Catalog (PAEC) lists completed and planned exposures. For planned exposures, conflict types are indicated. The PAEC is appropriate for observers who are planning to submit proposals for HST. (See the files `paec.cat` and `paec_ss.cat`.)
- The Archived Exposures Catalog (AEC) lists exposures which have been completed and have been archived into the HST Archive. The AEC is useful for Archive researchers; more information about exposures in the HST Archive is available through StarView. (See the files `aec.cat` and `aec_ss.cat`.)

The easiest way to access these catalogs is through the World Wide Web at: `http://archive.stsci.edu/ascii_catalogs.html`

6

Advanced StarView Queries

In This Chapter...

StarView provides two powerful tools for specifying your own customized searches of the Hubble Space Telescope (HST) catalog: a custom query feature and a Structured Query Language (SQL) editor.

StarView's custom query feature lets you construct your own custom queries (i.e., searches) of the HST catalog. This query can have one catalog field or many fields (current limit is 112). Typically, you would use this feature when the predefined StarView screens do not have the information (i.e., the catalog fields) that you are interested in. With the custom query feature, you can choose to display a wide variety of catalog information on a single screen, picking and choosing from among all of the available fields and tables in the HST catalog. For example, you may want to display target names and proprietary data release dates (and nothing more) on a simple table format screen, or you may want to display some of the target flux information that is not provided on any of the predefined StarView screens. With the custom query feature, you control what information is displayed. A complete list of all StarView tables and attributes can be found in the *Data Description* supplement.

The SQL editor lets you make searches of the HST catalog that cannot be defined on any of the normal StarView search screens. With the <SQL Editor> screen, you can display and modify the SQL commands for the current query, display and modify a set of SQL commands copied from an external file, or enter your own SQL commands. Typically, you would do this when you want to make some specific queries of the HST catalog that involve SQL constructs that are not possible through the normal procedure of entering constraints on a predefined StarView search screen. For example, you would use the SQL editor if you wanted to list all unique values of a specific field in the catalog, or if you wanted to impose a logically complex combination of constraints on the catalog search.

Using the Custom Query Feature

StarView's predefined screens are designed to satisfy the needs of most archive users. However, only a small fraction of the fields in the database are contained on the predefined forms. StarView's custom query feature lets you select other fields in the database of interest and construct queries with these fields.

To build a custom query, you:

1. Select fields (attributes) from the database in which you are interested.
2. Constrain your search by placing limits on some of these fields.
3. Begin the search.
4. View the results.

You can also save the query to a file so that you do not have to repeat the setup process.

Selecting Fields From the Database

The first step in building a custom query is to select fields (attributes) from the database. A list of all possible attributes is presented on the <Custom Query> screen. You may optionally filter and sort this list to derive a subset of attributes from which to choose. Then you can select attributes from the list that will define your search. The procedures for selecting fields from the database are further explained below.

1. Display the <Custom Query> screen by selecting **|Build Custom Query|** from the |**Commands|** menu on the <Welcome> screen or from the **|Customize|** menu on other StarView screens.

   An example of what may be displayed is shown below:

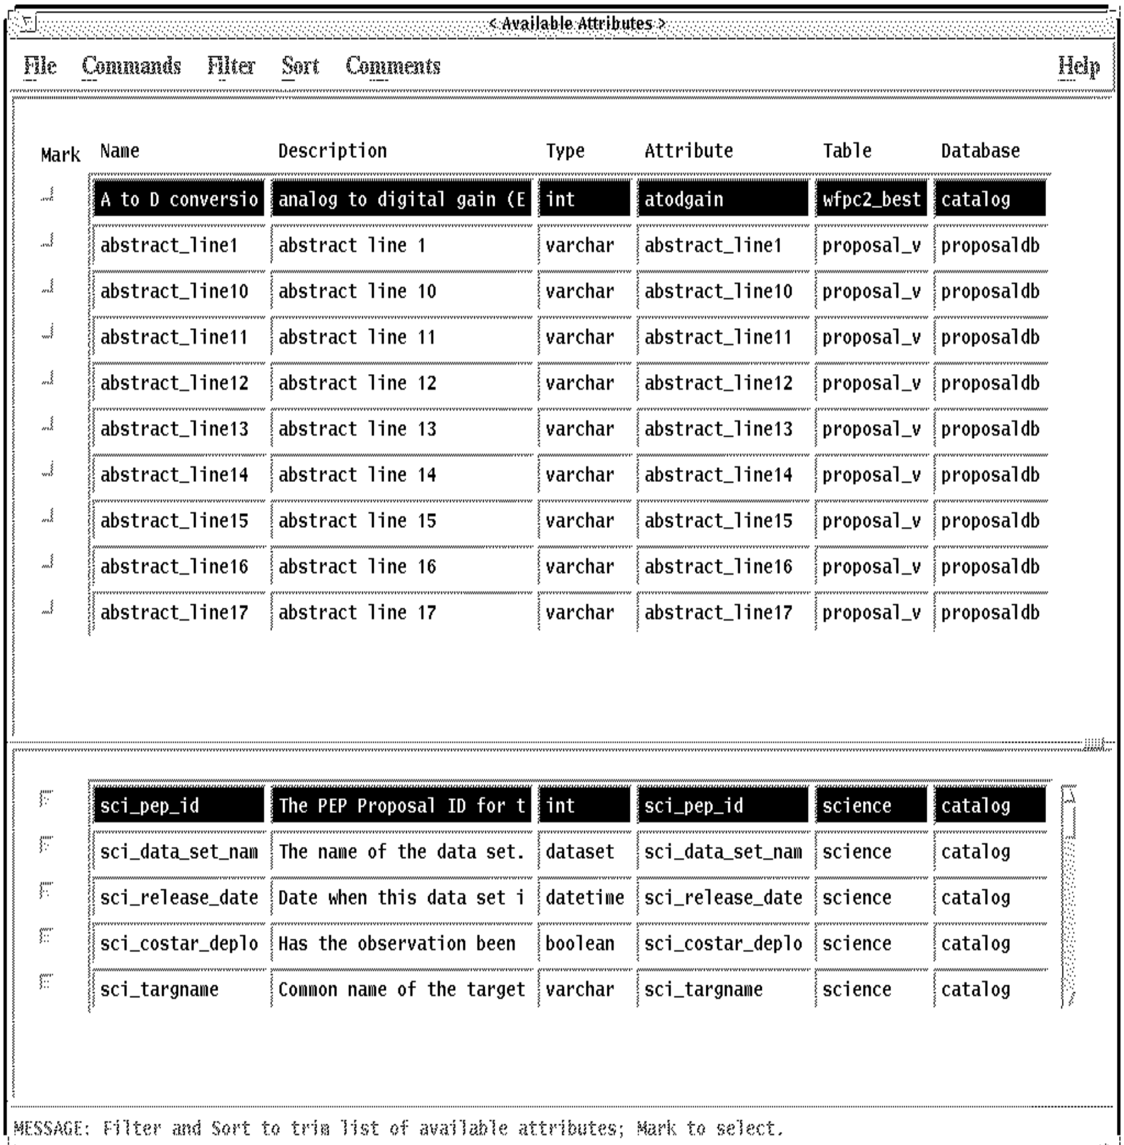

Figure 6.1: <Custom Query> Screen

If you display the <Custom Query> screen from the <Welcome> or <Table Format> screen immediately after you start up StarView, no attributes will be preselected (i.e., the bottom list will be empty). If you display the <Custom Query> screen from a search screen, attributes corresponding to the field labels on the search screen will be preselected and will appear in the lower list. Select **|New|** from the **|Commands|** menu of the <Custom Query> screen to remove all of the attributes in the select list and to begin a new search.

On the <Custom Query> screen, database attributes (fields) are displayed in two lists. The upper list displays the available database attributes. You can select attributes from this list that you wish to include in the current query.

Attributes that you select for inclusion will appear in the lower list. Attributes can be removed from the select list at any time.

Each attribute is defined by a row in the lists. Scroll up or down, with the arrow keys, to view additional or previous rows. Scroll right or left within a field (column) to view information that extends beyond the field boundaries.

Filtering Attributes

2. To filter your list of available attributes, select an item from the **|Filter|** menu.

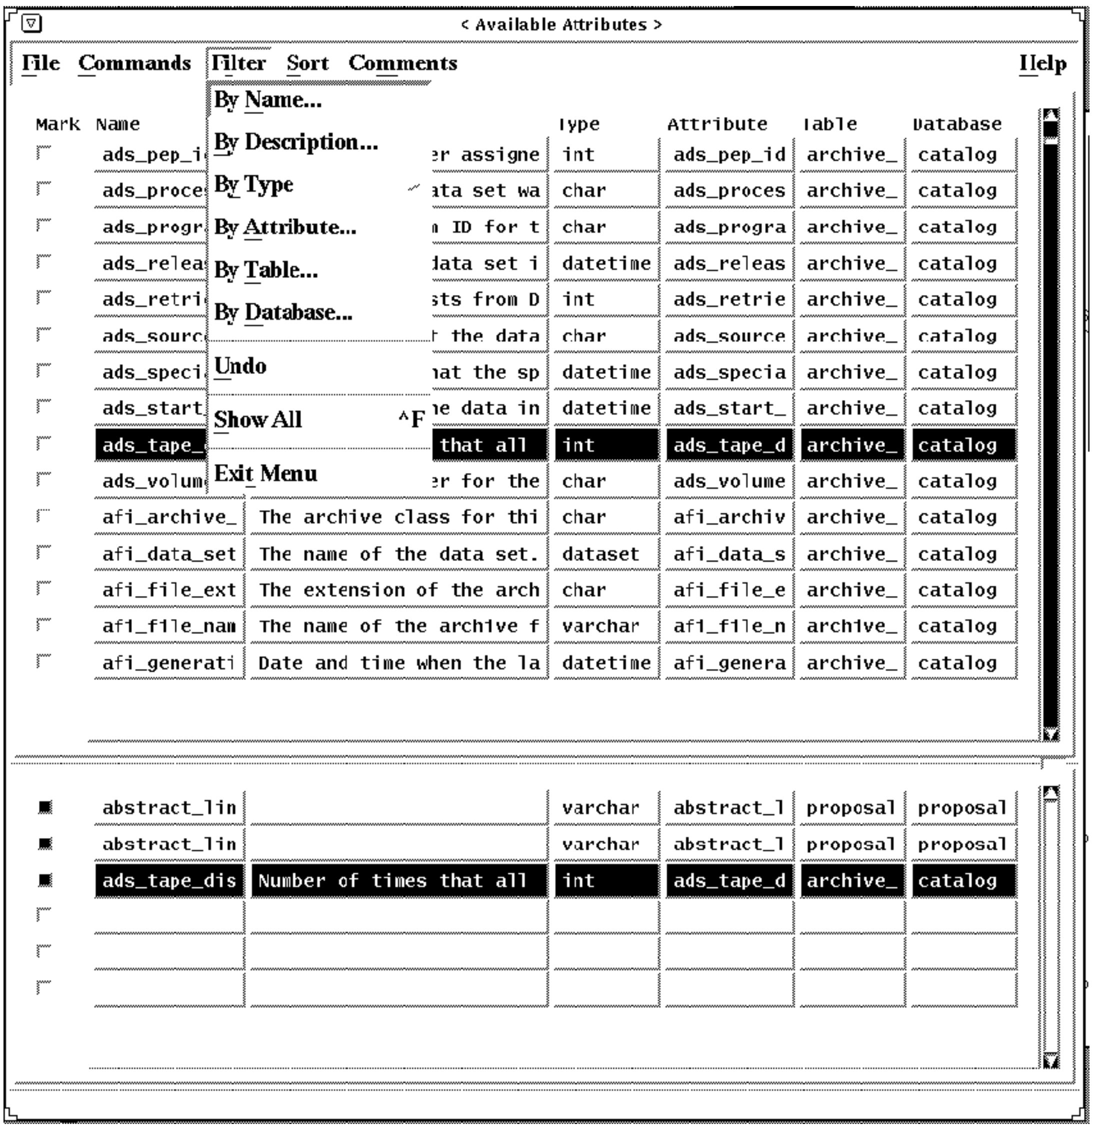

Figure 6.2: |Filter| Menu

Filtering limits the set of attributes that are displayed to a subset of the attributes in the database.

Each successive filtering further narrows the available attributes in the upper list. Select **|Undo|** to undo the last filter operation performed in the current session. Select **|Show All|** to restore the list of all available attributes.

If you select **|By Name|**, **|By Description|**, **|By Attribute|**, **|By Table**|, or **|By Database|**, a dialog box will appear, prompting you to type a name or description. Type a complete or a partial name or description. If you filter on a partial name or description, attributes with those characters in any position in their name or description will be displayed. If you select **|By Type|**, a submenu will appear.

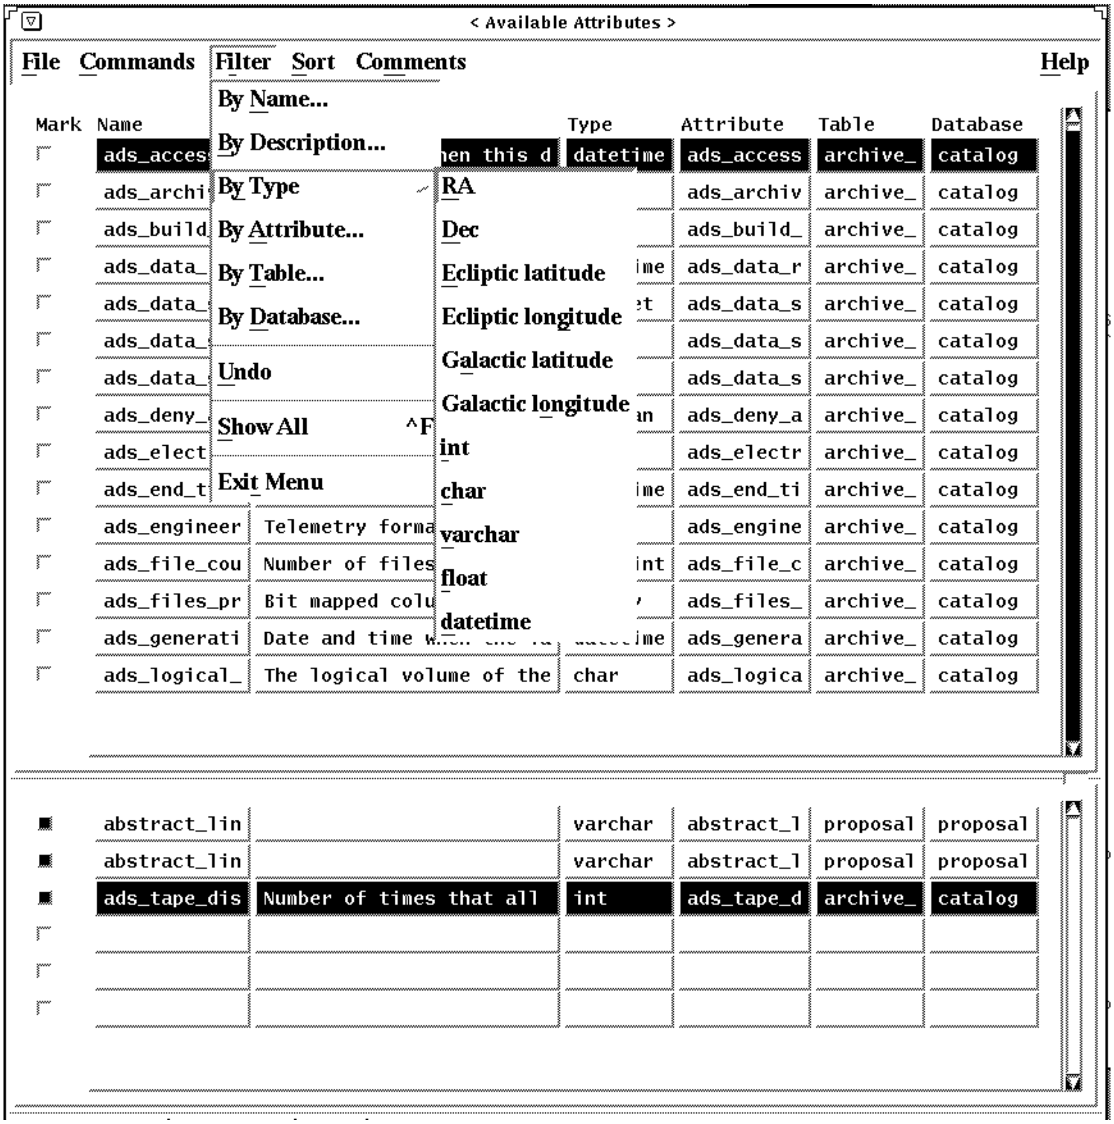

Figure 6.3: |By Type| Submenu

Choose a data type from the submenu.

Sorting Attributes

3. To sort your list of available attributes, select **|By Name|**, **|By Type|**, **|By Attribute|**, **|By Table|**, or **|By Database|** from the **|Sort|** menu.

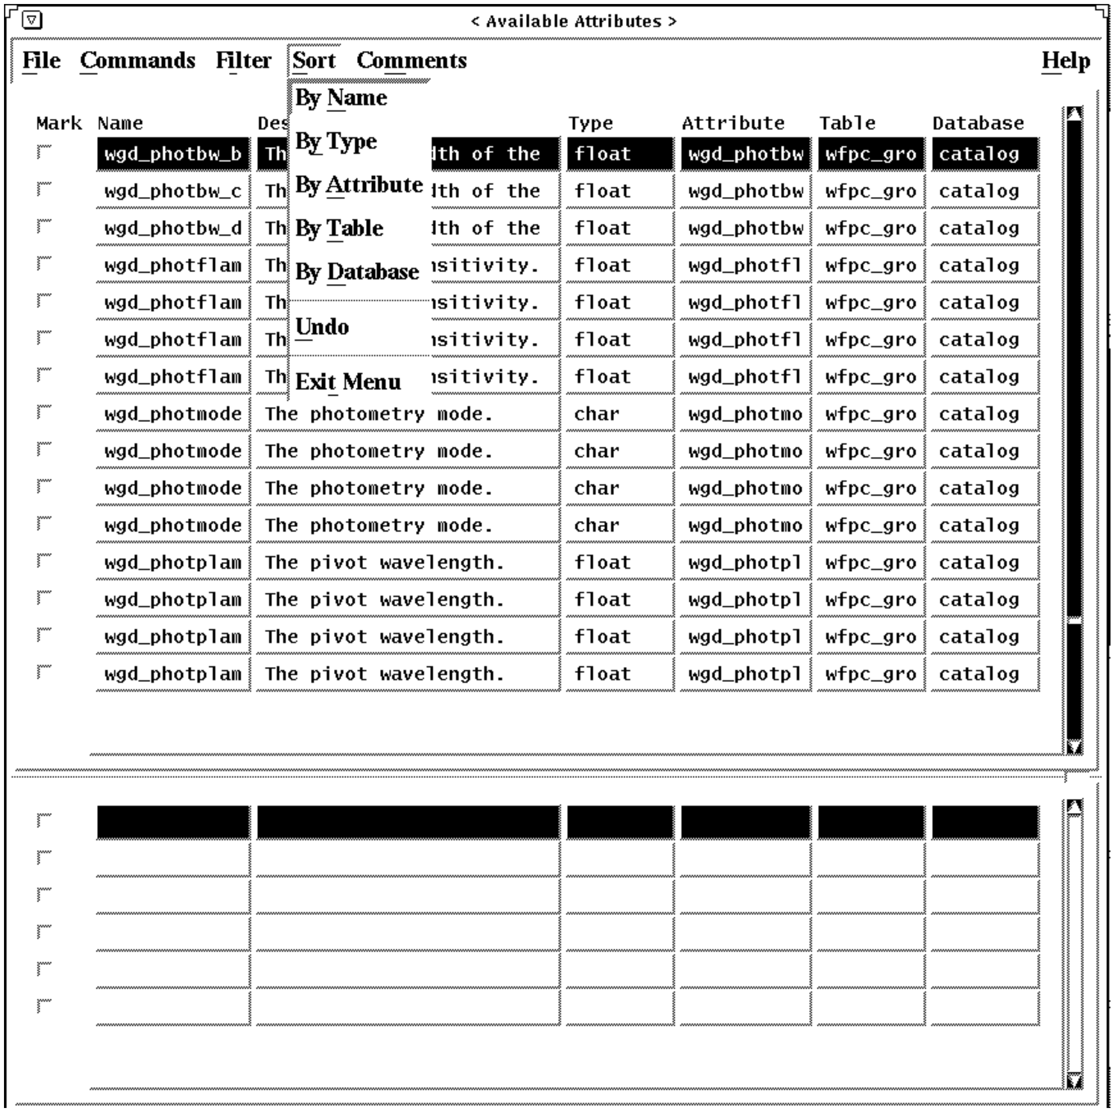

Figure 6.4: |Sort| Menu

Available attributes in the upper list will be sorted alphabetically by the menu item selected. Successive sorting operations are not cumulative. Select **|Undo|** from the **|Commands|** menu to undo the last sort operation for the current session.

Selecting Attributes

4. To select an attribute to include in the current query simply click the corresponding **[Mark]** button. (You could also highlight the attribute and choose "Select" from the **|Commands|** menu). The attribute will be displayed in the lower list of selected attributes with a tick mark next to the name (see Figure 6.5). You can select a maximum of 112 attributes to include in a query.

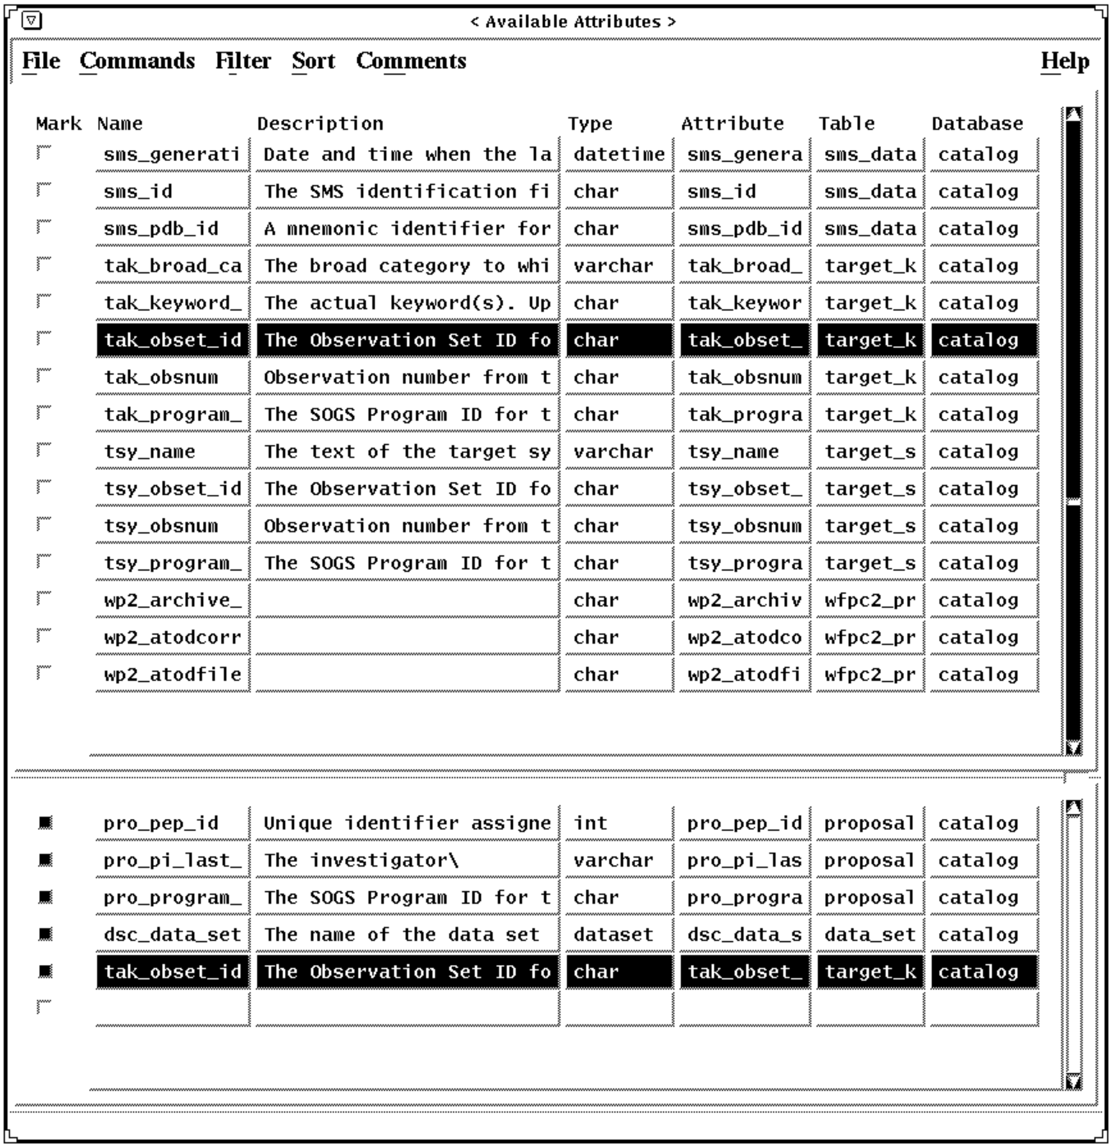

Figure 6.5: Selected Attributes on the <Custom Query> Screen

You can select all of the attributes displayed in the available list by choosing **|Select All|** from the **|Commands|** menu.

Removing Attributes

5. You can remove attributes from a query if you exceed the 112-attribute limit or otherwise don't want to include them in the query.

From the list of selected attributes (lower list), simply click on the **[Mark]** button. Alternatively, from the list of available attributes (upper list), you can either click on the **[Mark]** button or highlight a selected attribute and then choose “Deselect” from the **|Commands|** menu.

Either way, the tick mark will disappear, and the attribute will be removed from the lower list of selected attributes.

Completing the Selection

6. After compiling a list of selected attributes, choose **|Done|** from the **|Commands|** menu.

This will dismiss the <Custom Query> screen and let you constrain your query. Alternatively, selecting **|Exit Screen|** will abandon the custom query and return you to your previous StarView screen.

If you select **|Done|** to proceed with the custom query, you will invoke the <Table Format> screen.

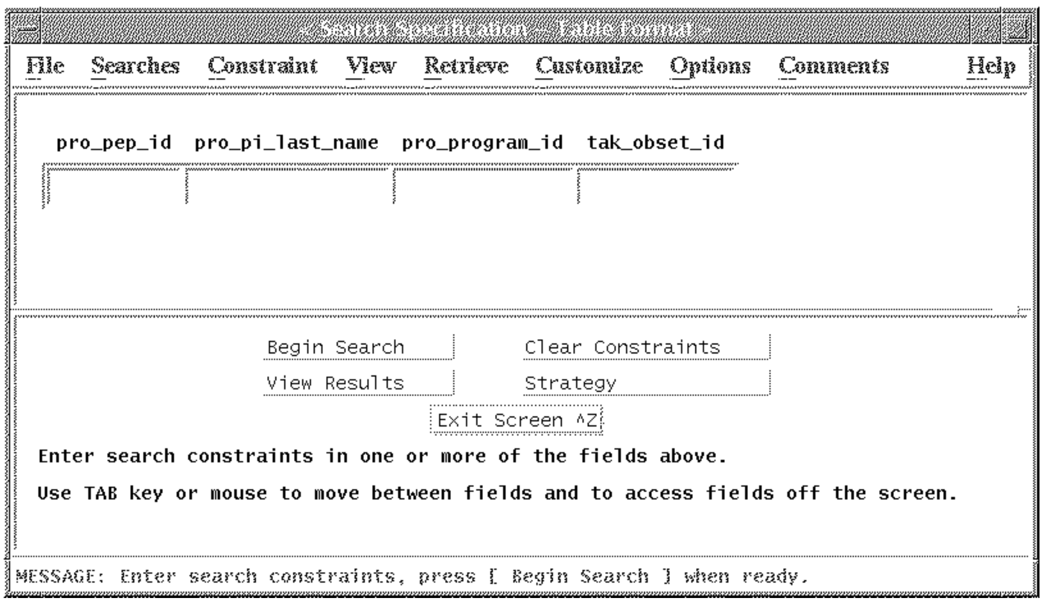

Figure 6.6: <Table Format> Screen

Your selected attributes will now appear as column headings on the <Table Format> screen in the order that they appear in the selected list on the <Custom Query> screen. You can constrain searches, view returned records, and save a query from the <Table Format> screen (see page 103).

Constraining Your Search

7. To constrain your search, move the cursor to one or more underlined fields in the first row of the <Table Format> screen and enter your search constraints.

StarView validates user input; therefore, search constraints must be correctly formatted. Constraints on the <Table Format> screen should be formatted the same as those on other search screens. For more information on validating user input and formatting search constraints, see page 37.

Initiating Your Custom Query Search

8. Initiate a custom query search from the <Table Format> screen by pressing **[Begin Search]**.

Viewing Returned Records

9. Your search results will be displayed on the <Table Format> screen (see below):

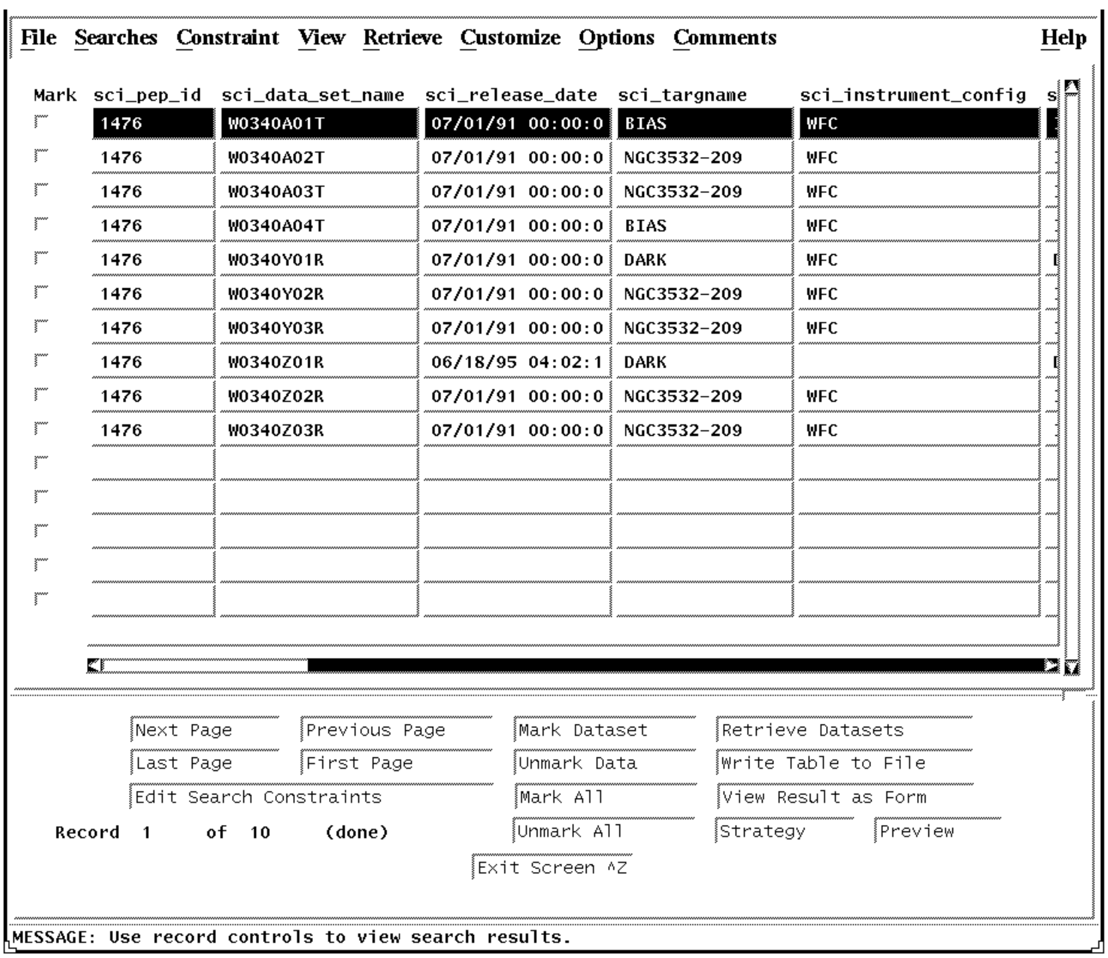

Figure 6.7: <Table Format> Screen With Search Results

For more information on using the <Table Format> screen, see page 105.

Cancelling A Custom Query

Press Control-C before the first record is returned to cancel a custom query. You may want to cancel a custom query if you built or qualified it incorrectly, or if the database search for matching records is taking too much time.

Modifying a Custom Query

You can modify the search constraints or the fields used in a custom query. If you modify fields (i.e., database attributes), a new query will be constructed, and you will lose the current search constraints, but not your choice of fields. To modify search constraints or database attributes, follow the instructions on page 104.

Saving a Custom Query

You can save a custom query in a file for later use. Follow the instructions for “Saving a Query” on page 103.

Restoring a Custom Query

You can restore a custom query that was previously saved to a file. Follow the instructions for “Restoring a Query” on page 103. Once you have restored a custom query, you can modify it or use it as is to browse the catalog.

Using the SQL Editor

StarView searches are automatically translated into SQL.[1] Through the <SQL Editor> screen, you can display SQL for the current query or from an external source, or enter your own SQL. You can also edit your SQL, submit it, and view results as you would with any other query. Procedures for using the <SQL Editor> are explained below.

---

1. SQL query generation is performed by a system called QUICK, which stands for “Quick is a Universal Interface With Conceptual Knowledge.” QUICK was developed by Dr. Ralph Semmel of the Johns Hopkins University Applied Physics Laboratory. It is written in CLOS and is integrated in StarView using the Lisp-to-C Translator™ from Chestnut Software, Inc.

What is SQL?

SQL is a language designed for relational database management systems. For example, StarView supports the Sybase database management system. In a relational database management system, data are presented as tables (also known as relations). Each row of the table is a record of a single entity. Each column describes a characteristic (attribute) of an entity.

Typically, StarView translates a user's catalog search request into SQL. The SQL is then used by the archive's database engine, Sybase, to provide the search results. This translation is automatic. It is based on the attributes selected from the <Custom Query> screen or on the fields displayed on the current search screen. This automatic translation into SQL is one of StarView's most powerful features. It allows you to access most of the fields in the HST catalog, without you having to be a database expert.

There are many special cases, however, that would require a knowledgeable user to query the database directly. It is primarily for these cases that the <SQL Editor> screen was provided. Through it, users are able to formulate directly arbitrary SQL statements for the database to process.

The general benefit of the <SQL Editor> screen for most StarView users is the ability to save queries (including your entered search constraints) for later reuse.

Displaying SQL for the Current Query

To display SQL for the current query, select **|Edit SQL|** from the **|Customize|** menu of a search screen. The <SQL Editor> screen will appear.

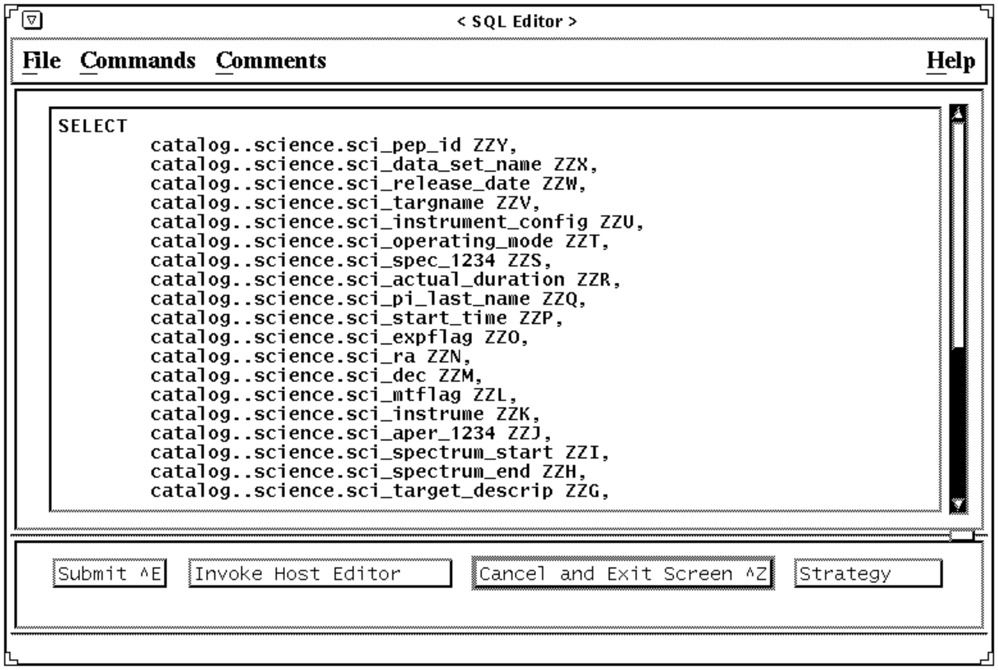

Figure 6.8: <SQL Editor> Screen

Scroll vertically with the arrow keys to view text on this screen that may extend beyond the screen's boundaries.

Displaying SQL From an External Source

Display SQL from an external source by selecting **|Restore Saved SQL From File|** from the **|File|** menu of the <SQL Editor> screen. The <File Selector> dialog box will appear.

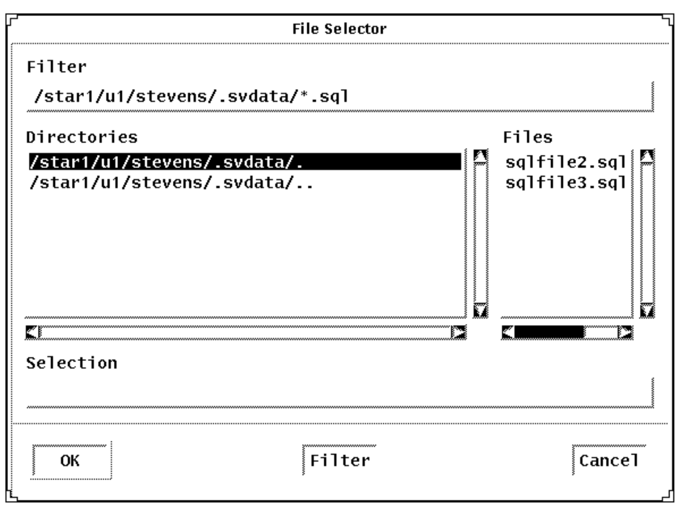

Figure 6.9: <File Selector> Dialog Box

For more information on the <File Selector> dialog box, see page 133. Select a file from this dialog box, then press **[OK]** to read the file and display the SQL. Press **[Cancel]** to dismiss the dialog box without opening a file.

Entering Your Own SQL

To enter your own SQL, display the <SQL Editor> screen from the <Welcome> screen or from a search screen. If displayed from the <Welcome> screen immediately after startup, the <SQL Editor> screen is initially blank, allowing you to formulate arbitrary SQL statements. If displayed from a search screen, this screen contains the SQL for the current query, even if this search has not been submitted for processing. Select **|Clear Screen/Enter New SQL|** from the **|File|** menu to delete the SQL and begin a new query. Consult the references listed on page 95 to find out how to construct SQL statements.

Editing SQL

You can edit SQL directly on the <SQL Editor> screen. See key help for key bindings that you can use on this screen.

Alternatively, you can use an external text editor (e.g., Emacs or EDT) to edit the SQL, as indicated below:

1. Save the SQL to a file by selecting **|Save Current SQL|** or **|Save Current SQL As|** from the **|File|** menu.
2. Temporarily exit StarView by selecting **|Escape to Operating System|** from the **|File|** menu.
3. Edit the SQL file.
4. Log out of the system shell to return to StarView.
5. Open the edited SQL file by selecting **|Restore Saved SQL From File|** from the **|File|** menu.

Submitting an SQL Query

To submit an SQL query, click on the **[Submit]** button or select **|Submit|** from the **|Commands|** menu.

Viewing Returned Records

Returned records are displayed on the <Table Format> screen. See page 105 for more information on using the <Table Format> screen.

Cancelling an SQL Query

Press Control-C before the first record is returned to cancel a query. You may want to cancel an SQL query if you entered or edited it incorrectly, or if the database search for matching records is taking too much time.

Saving an SQL Query

You can save an SQL query in a file for later use. Follow the instructions for “Saving a Query” on page 103.

Queries saved from the <SQL Editor> screen can be opened only on this same screen.

Restoring an SQL Query

You can restore an SQL query that was previously saved to a file. Follow the instructions for “Restoring a Query” on page 103. Once you have restored an SQL query, you can edit it or use it as is to browse the catalog.

Cross Correlation

If you are interested in finding out whether HST has observed a few individual sources, then you can simply search for matches between the HST catalog and those sources one at a time. However, if you have a list of sources whose RA and Dec you know, Starview provides a cross correlation capability that will search for matches between all members of your input list and the HST catalog.

The cross correlation capability is available on all StarView screens that have RA and Dec fields on the qualification form. It is easy to use. Simply click on the **[Cross Correlation]** button at the bottom of the screen. A dialog box will pop up requesting the name and location of the input list file. Your input list should contain multiple lines, each with a format of RA, Dec, and an optional comment, where the RA, Dec, and comment must be separated by commas or spaces. The RA and Dec must be in J2000 coordinates and can be written either as hh mm ss.s etc., or in decimal degrees. Declinations must include the +/- sign. Currently, the cross correlation facility supports input lists of 500 lines or less (depending on your system, larger input lists may be possible, but are not guaranteed).

To use the cross correlation feature in StarView:

1. Select pull-down menu item from the Constraint menu or select the **[Cross Correlation]** button.
2. A file selector dialog screen will pop up asking for the name of the cross correlation file. By default, it looks for the file `xcorrfile.lis` in your current directory.
3. The radius field will be given a default value of 10 if there is currently a value of 0 in the field. Otherwise, it maintains its original value.
4. Enter any additional constraints (e.g., qualify on instrument or exposure start time). You can also change the search radius at this time.
5. Click the **[Begin search]** button. This will search the database for values matching each line of the correlation file.
6. If a match is found the screen will switch to the view results screen. You can step through the returned records one at a time or switch to table row form. All of the normal functionality (e.g., preview) is available to you. On some screens (e.g., the <Duplication Check> screen) you will see information about the line from your input list displayed directly on the return screen (specifically the input line number, RA and Dec and comment). For screens where this information is not visible on the screen, the information is available in the table row format; it appears as the first 4 columns of the table row format, so you will have to scroll the screen to see most of the other values.

Your query will remain in cross correlation mode until you click on the **[Clear Constraints]** button on the qualifying screen, or until you exit the screen completely.

Users should be aware that a cross correlation facility is also available via the WWW interface at `http://archive.stsci.edu/search/` (see “Cross-Correlations” on page 22). The WWW interface also allows the cross-correlation of the HST and MAST catalogs with selected astronomical catalogs.

7 Additional StarView Topics

In This Chapter...

Once you are comfortable with the basic procedures for using StarView, you may want to try some of the additional features explained in this chapter.

Entering Data on a StarView Screen

StarView recognizes only certain data formats for search constraints. Table 7.1 provides examples of these data formats.

Data Type[a]	Examples of Allowable Formats
String	G190H, Y0ML0104T, PG0953+414, Stellar Cluster, FO*[b]
Boolean	Y, Yes, N, No, T, True, F, False, 1, 0
Integer	0, 13, 256
Float	1.5, 15.32, 153.26
Date/Time[c]	January 1 1990, January 1 90, Jan. 1 1990, Jan 1 1990, 1-Jan-1990, 1Jan1990, 1 Jan 90, 1/1/1990, 1-1-90, 1.1.90 12:24:32.4, 12 24 32 4, 12.24.32.4[d] January 1 1990 12:24:32.4[e]
Angle	See Table 7.2.

a. You can use relational operators (e.g., >, >=, =) with any data type except string. See Table 4.1 on page 37 for a list of relational operators that you can use in search constraints.
b. You can use wild cards only with the string data type.
c. Do not use commas in times and dates (example: May 1, 1990). The comma will be incorrectly interpreted as a list separator.
d. You may use 24-hour time with or without specifying AM or PM. You must specify AM or PM for 12-hour time.
e. When you specify both a date and a time for a constraint, type the date first, insert at least one blank space, then type the time.

Table 7.1: Allowable Data Formats

More on Formatting Search Constraints

The subsections below explain the rules for formatting search constraints. Specifically explained are:

- Using wild cards.
- Relating search constraints with “and” or “or”.
- Formatting positional values.
- Using spaces in search constraints.

You can also enter constraints with relational operators. For information on the relational operators that StarView supports, see page 37.

Using Wild Cards

You can (and often should) include wild cards in character fields. Note that date and time fields are numerical fields. Specify a wild card by typing the star symbol (*).

Wild cards let you specify multiple selections with related names, without having to specify each selection by its full, unique name. Use the wild card symbol to match zero or more characters. You can use more than one wild card in each item. For example:

```
Target: NGC*
```

The “*” is StarView’s wild card symbol. StarView converts this symbol to the equivalent symbol that the database management system, Sybase, needs for searching the catalog. See also the note on page 102.

See “Text Searches” on page 38.

Relating Search Constraints With “And” or “Or”

StarView lets you constrain multiple fields in a single search. Multiple search constraints are related by “and” by default. For example:

```
Proposal ID: >1000
Target: NGC4473-WFPOS-CNTR
```

This will return all records where the proposal ID is greater than 1000, and the target is NGC4473-WFPOS-CNTR. To relate search constraints by “or,” you must use the Structured Query Language (SQL) editor.

```
SELECT

proposaldb..proposal_info.pep_id ZZY,
proposaldb..proposal_info.continuation_id ZZX,
proposaldb..proposal_info.prop_type ZZW,
proposaldb..proposal_info.sci_category ZZV,
proposaldb..proposal_info.proposal_cycle ZZU,
proposaldb..proposal_info.pi_lastname ZZT,
proposaldb..proposal_info.proposal_title ZZI

FROM
proposaldb..proposal_info

WHERE
(proposaldb..proposal_info.sci_category LIKE "%GALAX%"
OR
proposaldb..proposal_info.proposal_title LIKE
"%GALAX%")
```

(The purpose of this search is to find all observing programs that are either in the Galaxies & Clusters category or which may be in another science category, yet contain the words “Galaxy” or “Galaxies” in their proposal title.)

The “%” is the wild card symbol for StarView’s database management system, Sybase. When you enter SQL directly on the SQL Editor screen, you must use this wild card symbol. See also the note on page 101.

Formatting Positional Values

Positional values are RA, longitude, Dec, and latitude. When constraining searches, format RA and longitude as 00h 00m 00.0s and Dec and latitude as 000d 00m 00.0s. You can also format search constraints for these items as shown in Table 7.2.

RA and Longitude		Dec and Latitude	
You enter:	**StarView assumes:**	**You enter:**	**StarView assumes:**
000:00:00.0	hms	000:00:00.0	dms
000 00 00.0	hms	000 00 00.0	dms
0000000.0	hms	0000000.0	dms
000.0	deg	000.0	deg
000d 00m 00.0s	dms	000d 00m 00.0s	dms
000d 00' 00.0"	dms	000d 00' 00.0"	dms

00.000h	hr		

Table 7.2: Formatting Positional Values

Using Spaces

Leading and trailing spaces are ignored. Multiple spaces in a row are treated as one space. Spaces are significant in fields where you enter dates, times, or positions (RA and Dec). For example:

```
Observation date: 23 03 92
Observation time: 07 02 17
```

Using a Previous Query

If you routinely perform the same basic search, you may want to save it (including the search constraints) for future use. You can later restore and even modify it for reuse. The sections below explain these functions.

Saving a Query

If you want to search the catalog at a future time with a particularly defined query, save it to a file by selecting **|Save Current SQL|** or **|Save Current SQL As|** from the **|File|** menu of the <SQL Editor> screen, or **|Save Current Query|** or **|Save Current Query As|** from the **|File|** menu of the <Table Format> screen. The save function overwrites any existing file of the same name. If you have not yet saved the current query, the <File Selector> dialog box will appear, prompting you to name the file that will contain the current query. For more information on the <File Selector> dialog box, see page 133.

StarView also automatically saves the current query in a file once a search begins. Therefore, you can use this file (`previousquery.sql` for queries saved from the <SQL Editor> screen and `previousquery.qry` for queries saved from the <Table Format> screen) to restore the previous search (see below).

You can externally edit any of these query files to modify the search request. When you restore an edited file, the modified query is used.

Restoring a Query

To search the catalog with a previously defined query:

1. Select **|Restore Saved SQL From File|** from the **|File|** menu of the <SQL Editor> screen or **|Restore a Saved Query|** from the **|File|** menu of the <Table Format> screen.

The <File Selector> dialog box will appear and will display a list of saved files. For more information on the <File Selector> dialog box, see page 133.

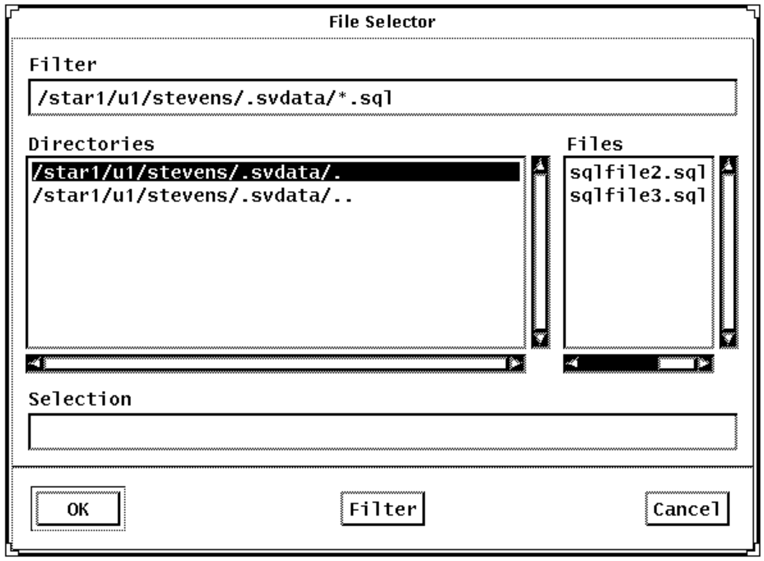

Figure 7.1: Saved Files Displayed on the <File Selector> Dialog Box

2. Select the file named `previousquery.sql` or `previousquery.qry` (whichever one is displayed) to restore the previous search, or select another saved query file.

   By default, query file names have a `.SQL` or `.QRY` extension.

Once you have restored a search, you can modify it or use it as is to browse the catalog.

Modifying a Query

You can modify the constraints or the fields used in a search. If you modify fields (i.e., database attributes), the constraints from the previous query are cleared. If desired, you can enter new constraints.

Modifying Search Constraints

To modify search constraints:

1. Display a query on a search screen or on the <Table Format> screen. Do this after you restore a query from a file, by pressing **[Submit]** on the <SQL Editor> screen.
2. Change, add, or delete search constraints.
3. Optionally, save the query.
4. Search the catalog by pressing **[Begin Search]**.

Modifying Database Attributes (Fields)

To modify the fields used in a search:

1. Open a query by selecting a predefined StarView search screen or by restoring a query file.
2. Display the <Custom Query> screen by selecting **|Build Custom Query|** from the **|Customize|** menu.

   For procedures on using this screen, see "Using the Custom Query Feature" on page 82.
3. Add or delete attributes in the selected attributes list (i.e., the lower list).
4. Select **|Done|** from the **|Commands|** menu to continue the modifications on the <Table Format> screen.
5. Optionally, constrain your search.
6. Optionally, save the query.
7. Search the catalog.

More on Viewing Records

This section explains how to view multiple records with the <Table Format> screen and how to write search results to a file. For basic procedures for viewing records, see Chapter 4.

Viewing Multiple Records With the <Table Format> Screen

The typical StarView results screen presents one record of catalog information at a time. As you know by now, you can display multiple records in a single table. Figure 7.2 shows a sample search results screen in table format.

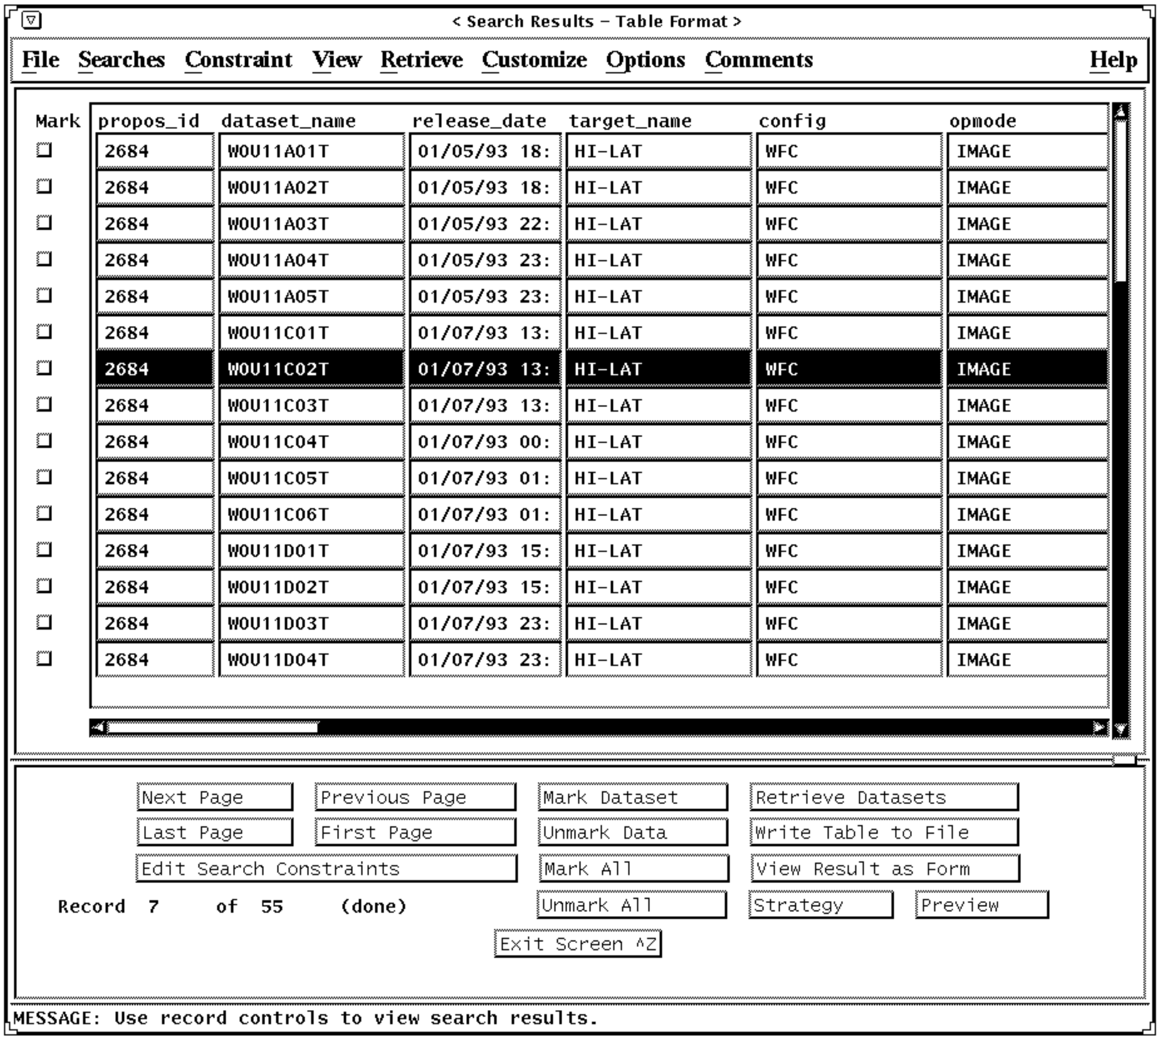

Figure 7.2: <Search Results - Table Format> Screen

The <Table Format> screen displays several records at one time for a limited number of fields (represented by the columns in the table). Scroll bars at the right and bottom of the screen allow you to modify the columns and rows displayed. Scroll the table left or right to view columns hidden off the sides. Moving left from the leftmost column will cause the next column hidden off the screen to be displayed. Likewise, moving right from the rightmost column will expose the next hidden column to the right.

StarView takes advantage of a larger screen. If you change the size of the table width by grabbing the corner with your mouse, StarView will adjust to the increased available space. You can change the column widths, delete, and rearrange columns with mouse commands and "click-and-drag" techniques. (See "Saving Search Results to a File" on page 42.) These changes will be reflected in the saved ASCII table if you do not then select the

[Select Output Columns], which enables you to quickly select a few columns, but wipes out any formatting you may have specified with mouse commands previously.

If you entered the <Table Format> screen from one of StarView's predefined search screens, then you can return to the corresponding single-record results screen by clicking the **[Exit Screen]** button.

You can begin another search on the corresponding search specification screen by pressing **[Edit Search Constraints]**. You can also enter search constraints directly in the table format (see below) immediately after pressing **[Edit Search Constraints]**.

The table format results screen has a search specification companion screen, also displayed in a tabular format. This is essentially the same search screen that appears whenever a custom query is generated (see page 82 and Figure 7.3). You can use this screen to conduct a search that constrains any of the available fields, in any combination. Enter search constraints in this way:

1. Enter the data area if necessary.
2. Click on a field that you want to be constrained.
3. Enter the constraint for that field.
4. Repeat steps 2 and 3 to constrain additional fields (see Table 7.2).

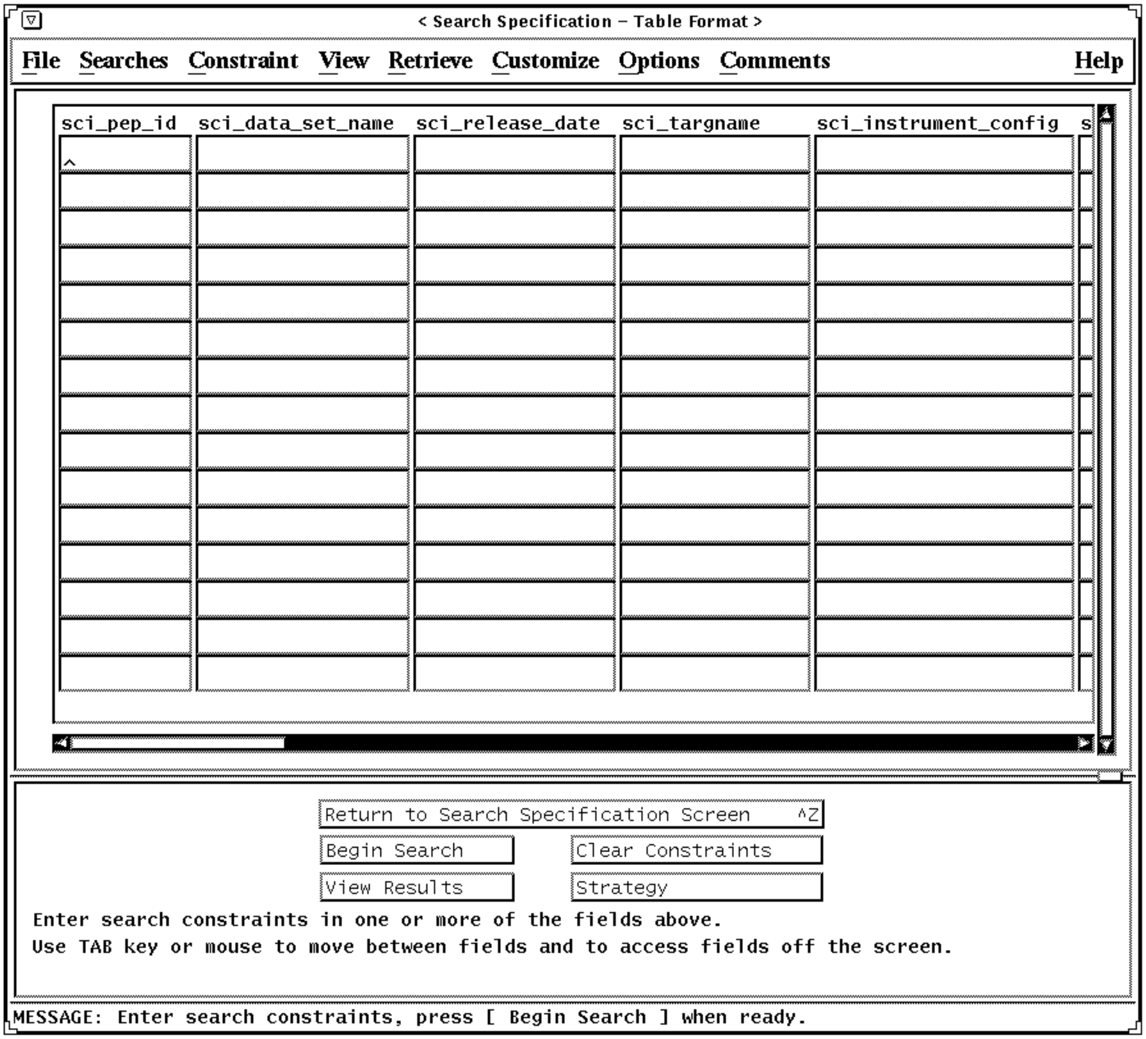

Figure 7.3: <Search Specification - Table Format> Screen

The catalog search is then initiated in the usual way by pressing **[Begin Search]**. The results of your search request will finally be returned on the corresponding <Search Results - Table Format> screen. As with any StarView results screen, you can write your search results to a file for later review by pressing **[Write Table to File]** (see page 109).

If you wish to retrieve the data associated with the datasets shown on the screen, press **[Mark All]** to retrieve all of the datasets corresponding to your search request. Press **[Mark Dataset]** to retrieve only the current dataset. On most user displays, the “current” dataset in the table format is the highlighted record (or the one appearing in bold type). As on other screens, the marking commands can be reversed, by pressing either **[Unmark Data]** or **[Unmark All]**.

[Unmark Data] operates only on the record that is currently highlighted in bold type.

The first column in a table format results screen has column heading “Mark.” This is the column in which marked datasets are identified. This column will have a “tick mark” value in the data area of the screen if the dataset has been marked for retrieval, and the column will be blank if the dataset has not been marked for retrieval.

You can write your search results to a file by pressing **[Write Table to File]** (see below). Before doing this, you may notice that there are some records that you are not interested in seeing. For example, a search for all observations of Jupiter may yield a number of satellite observations. You can therefore delete single or multiple records from your results table by selecting **|Delete One Record|** or **|Delete Range of Records|**, respectively, from the **|View|** menu.

Writing Search Results to a File

You can save your search results to a file for later use with other programs or analysis tools. To save your results:

1. Press **[Write Result to File]** on a search results screen or **[Write Table to File**] on the <Table Format> screen.

   The <Table Export> screen will appear.

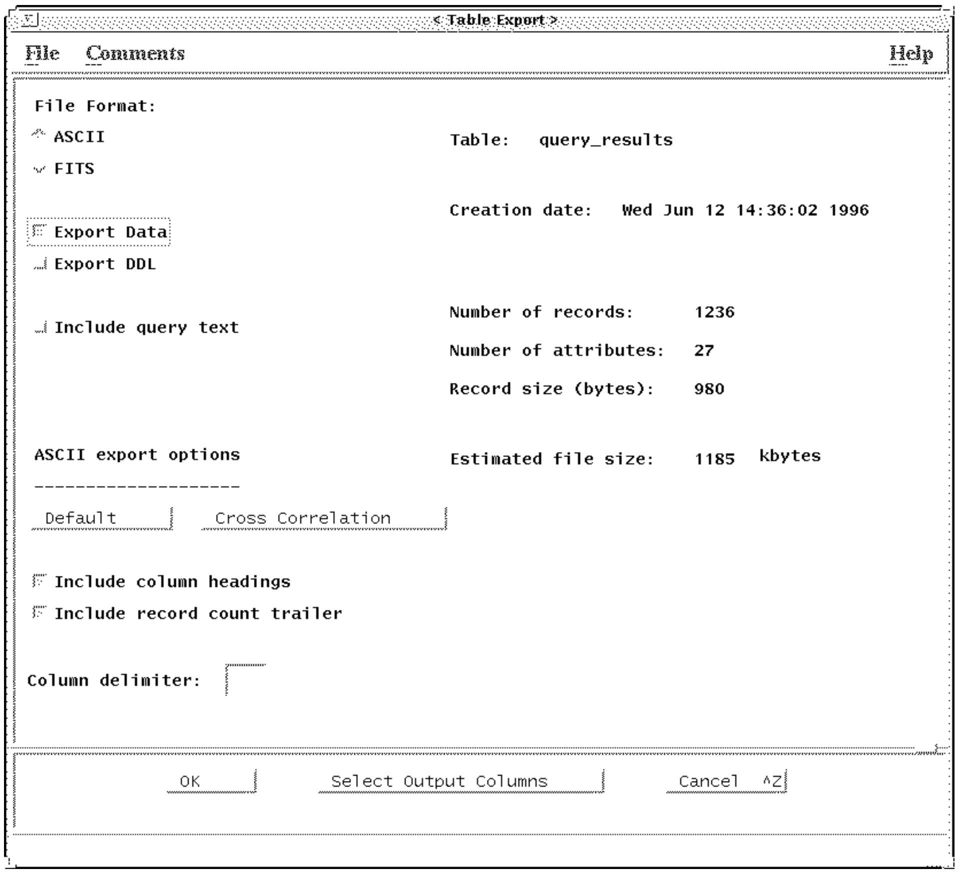

Figure 7.4: <Table Export> Screen

2. On the <Table Export> screen, choose output options from among the items listed on the left. Table 7.3 presents descriptions of these fields. (For more information about saving files, see "Retrieving Datasets From the Archive" on page 45.)

Choose this option:	Purpose
File Format[a]	
– ASCII	Format the exported table as an ASCII text file (default).
– FITS	Format the exported table as a standard FITS file, using the ASCII Tables Extension.
Export Data	Write the data table to the exported file (default).
Export Data Definition Language (DDL)	Generate an additional file describing the table structure (for example, field names, data types).
Include query text	Include, in the exported file, the Structured Query Language (SQL) statement that produced the data.
ASCII Export Options:	
– Include column headings	Include the database column headings in the file (default).
– Include record count trailer	Include, at the end of the file, the number of records in the table (default).
– Column delimiter	Override the character (a space) that StarView uses to separate the columns in the exported table. You can specify any ASCII character (or string) as the separator

a. Choose FITS if you plan to work much with the file. ASCII text wraps at the end of lines.

Table 7.3: Options on the <Table Export> Screen

3. Press **[OK]** to begin writing the search results to a file.

The <File Selector> dialog box will appear.

4. In the <File Selector> dialog box (see page 133 for information on how to use this dialog box):

- Specify the file to which the list will be written. Be careful to specify a new file name, unless you want to overwrite an existing file.
- Press **[OK]** to write the results to the file and to dismiss the <File Selector> dialog box. A large file may take several seconds to write.

Once the search results have been written, a dialog box will appear, requesting that you acknowledge the export.

5. Press **[OK]** to dismiss the dialog box and return to the search results screen.

More on Retrieving Data

This section explains how to specify datasets for retrieval both on the <Archive Retrieval> screen and directly using StarView's retrieval utility. For basic retrieval procedures, see Chapter 4.

Specifying Datasets on the <Archive Retrieval> Screen

You can use the <Archive Retrieval> screen directly to specify datasets for retrieval, in addition to any that you may have marked on the results screens. You can add datasets one at a time by name or add several dataset names at once from a file. If necessary, you can also unmark datasets on the <Archive Retrieval> screen or write the list of marked datasets to a file (for later use or for your records).

Adding Datasets by Name

To add a specific dataset to your archive retrieval list, do the following:

1. Press **[Add Datasets by Name]**.
2. Type a dataset name in the dialog box that appears.

   You can use uppercase, lowercase, or mixed case letters.
3. Press Return after typing the dataset name or **[OK]** to add the dataset name to the retrieval list.

   The added dataset will be displayed on the <Archive Retrieval> screen and will automatically be marked for retrieval. After the dataset is added, the "add dataset" dialog box will reappear.
4. Add another dataset, or press **[Cancel]** to dismiss the dialog box.

Adding Datasets From a File

To add several datasets to your archive retrieval list, using a file that contains a list of the dataset names, do the following:

1. Outside of StarView, create a file that contains a list of the desired dataset names.

   Place each dataset name on a separate line in the file. You can use uppercase, lowercase, or mixed case letters.
2. Within StarView, press **[Add Datasets from File]** on the <Archive Retrieval> screen.

The <File Selector> dialog box will appear. See page 133 for information on how to use this dialog box.

3. In the <File Selector> dialog box:

   - Select the file that contains the list of dataset names, or type the file name in the "Selection" field.
   - Press **[OK]** to read the file, to add the dataset names to the retrieval list, and to dismiss the <File Selector> dialog box.

   The added datasets will be displayed on the <Archive Retrieval> screen and will automatically be marked for retrieval.

Unmarking Datasets

Only marked datasets will be retrieved. Each of the datasets that initially appears when you enter the <Archive Retrieval> screen is already marked. You can unmark any of these if you decide not to retrieve it. Press **[Unmark One Dataset]** to unmark the current dataset (printed in bold type on the retrieval screen), or press **[Unmark All Datasets]** to unmark every item in the retrieval list. You can undo these actions and restore the original markings by pressing **[Mark One Dataset]** or **[Mark All Datasets]**, respectively.

Writing a Dataset List to a File

The list of datasets appearing on the <Archive Retrieval> screen can be written to a file. As described above, you can use this file (or an edited version) to add these datasets to a future archive retrieval list. To write the dataset list to a file, do the following:

1. Select **|Write Dataset List to a File|** from the **|View|** menu.

   The <File Selector> dialog box will appear. See page 133 for information on how to use this dialog box.

2. In the <File Selector> dialog box:

   - The filter is set in your home directory. If you wish to change directories, move the file.
   - Specify the name of the file that will contain the list. If you do not wish to overwrite an existing file, be sure to specify a new file name.
   - Press **[OK]** to write the dataset list to the file and to dismiss the <File Selector> dialog box.

Retrieving Data Directly

If you already have a list of datasets to retrieve and want to bypass searching and marking, you can use StarView's retrieve utility directly. But you will first need to initialize your system. On unix systems, type:

```
% source $starview_path/svinit.csh
```

On VMS system, type:

```
$ @STARVIEW:[STARVIEW.DIR]SVINIT
```

where the paths to `svinit` will vary from system to system and will depend on the location within your system of the StarView installation. If you have problems with this, see your system administrator.

Once you have your paths defined, you can retrieve using the following command syntax:

```
$ sv_dads_retrieve <dataset_list_file> [username password]
```

For example:

```
$ sv_dads_retrieve myfile.dat [Doe mypassword]
```

The *<dataset_list_file>* contains various options and datasets listed, one per line. For example,

```
BEGIN HEADER
     media NET
     host_computer kayak.stsci.edu
     host_directory /kayak/u1/jay/svdata
     data_calibrated TRUE
     data_uncalibrated FALSE
     data_oms FALSE
     data_usedref FALSE
     data_bestref FALSE
     classes
     extensions
     version 0# get the latest version (default)
END HEADER

V0ZF0102T
W12W0104T
X0XA0101T
Y0X30301T
Z0XZ0107T

END LIST
```

The “[ ]” symbol indicates that user name and password are optional. If you do not include them in the command, you will be prompted for them.

After typing the retrieve command, press Return. At this point, retrieval processing will be the same as if you had retrieved through StarView. Data will be written to a subdirectory of the `data` disk.

Modifying Your StarView Environment

StarView provides several screens that let you modify your StarView environment. Specifically, you can modify user defaults, archive retrieval defaults, output coordinates, and date and time formats.

To modify your environment:

1. Select a screen from the **|Options|** menu.

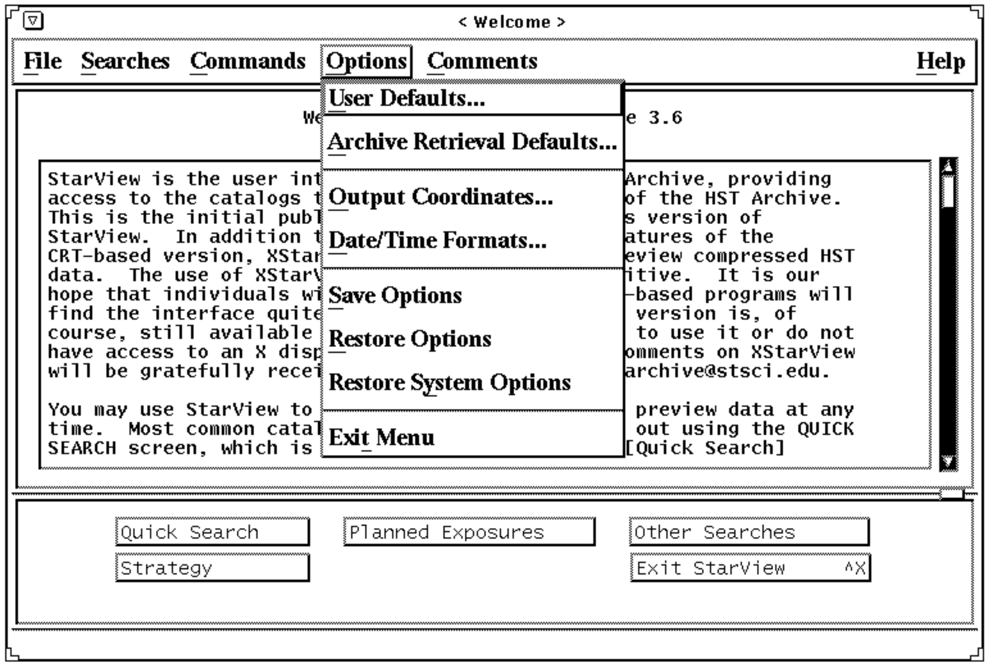

Figure 7.5: |Options| Menu

2. Choose new values for one or more fields on the screen.
3. Dismiss the screen and use the modifications for the current session by pressing **[OK]** or by selecting **|Exit Screen|** from the **|File|** menu.

You can use these new options for the current session only or save them for later reuse. On the **|Options|** menu:

Option	Purpose
|**Save Options**|	Save modifications for future sessions
|**Restore Options**|	Restore the startup values
|**Restore System Options**|	Restore StarView's default (original) values

Table 7.4: Commands in the |Options| Menu

You can modify particular components of your StarView environment by using the screens explained below.

User Defaults Screen

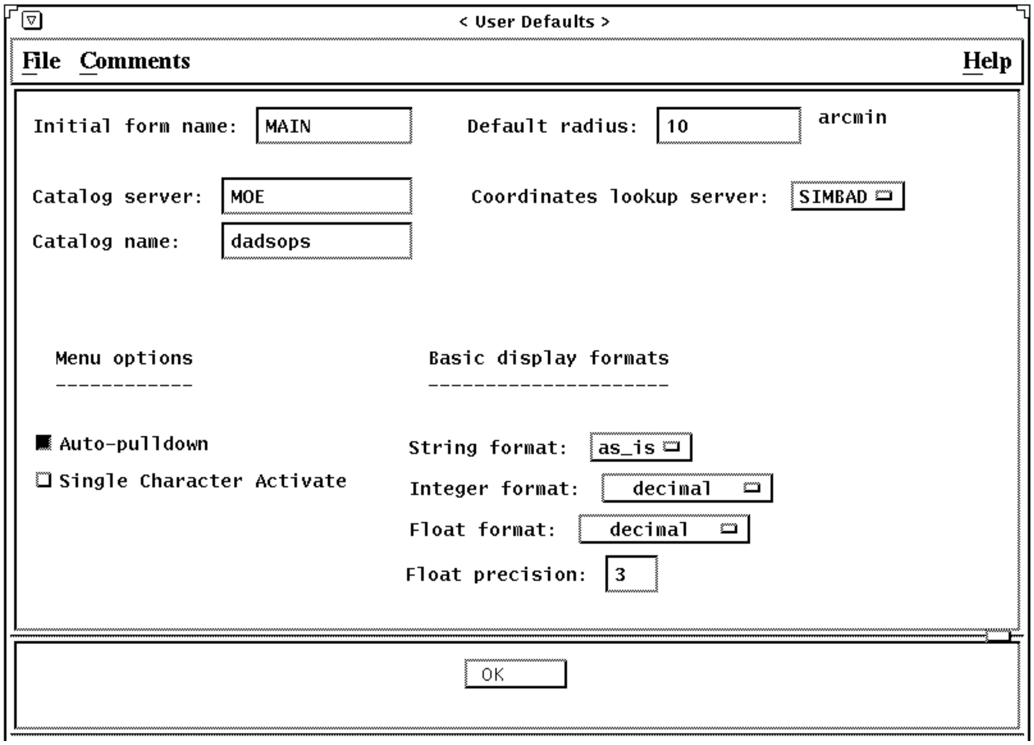

Figure 7.6: <User Defaults> Screen

This screen lets you modify the initial screen name, default catalog, menu options, default radius for circular-area searches around specific target positions, and basic display formats.

Field	Options
Initial form name	Type in the name of the StarView form that you want initially displayed after StarView starts up.[a] Examples: other_searches, proposal_abstract_qualify, quick_search_qualify, foc_qualify, hsp_ref_qualify, archive_retrieval, custom_query
Default radius	Examples: 1, 2, 3, ...
Menu options	Toggle selection. Auto-pulldown automatically displays the complete menu when you select the menu title. Single Character Activate allows you to execute a menu function by selecting it. Usually, you have to select a menu item and then press Return to execute the menu function.
Basic display formats	For String format, Integer format, and Float format, select an option from the popup choice list that is displayed when you select one of these items. For Float precision, type in an integer (e.g., 1, 2, 3, ...).
Coordinates look up	Select either SIMBAD or NED coordinate resolver

a. Exception: Instead of “welcome” type “main.”

Table 7.5: User Default Fields

Archive Retrieval Defaults Screen

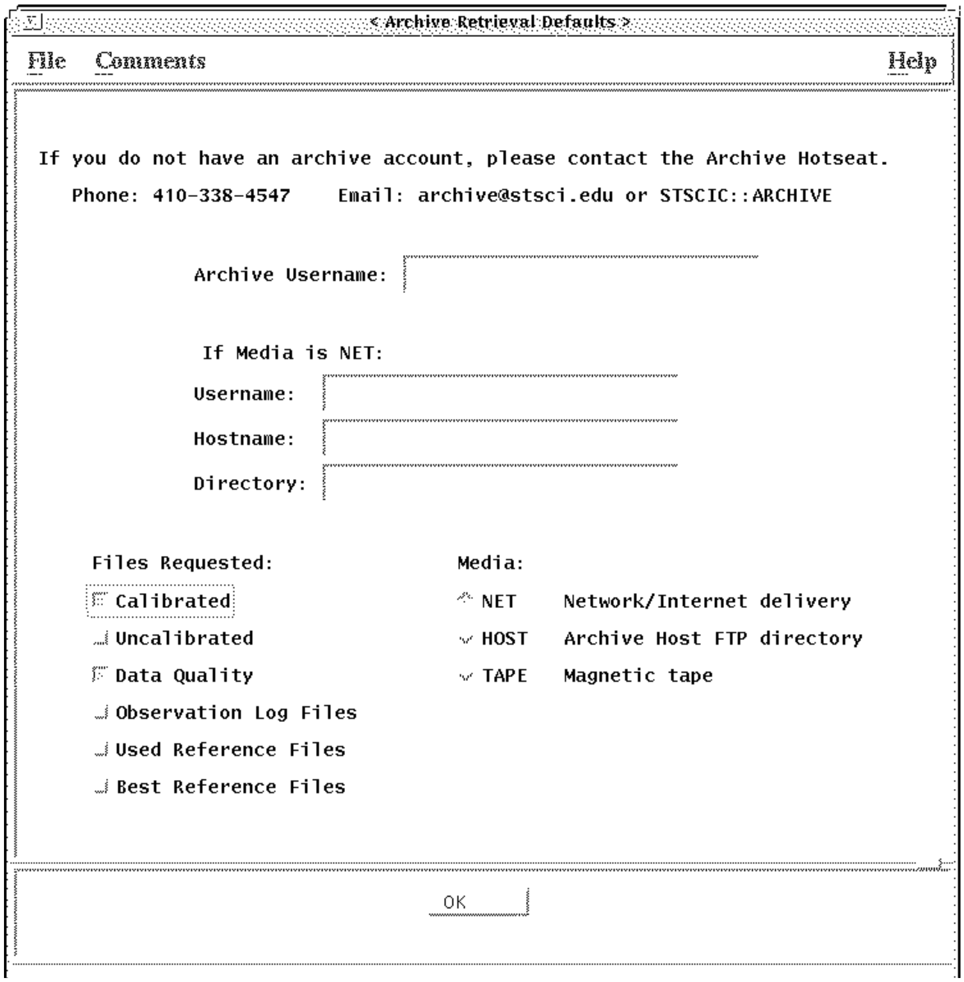

Figure 7.7: <Archive Retrieval Defaults> Screen

This screen lets you modify the defaults used in requesting datasets from the Hubble Space Telescope (HST) Archive.

Field	Options
Archive user name and password	Provide the user name and password that you were assigned when you registered as an archive user. See page 10 for registration procedures.
Files Requested	Toggle selection.
Media Format	Toggle selection. See “Specifying Formats and Media” on page 47.

Table 7.6: Archive Retrieval Options

Output Coordinates Screen

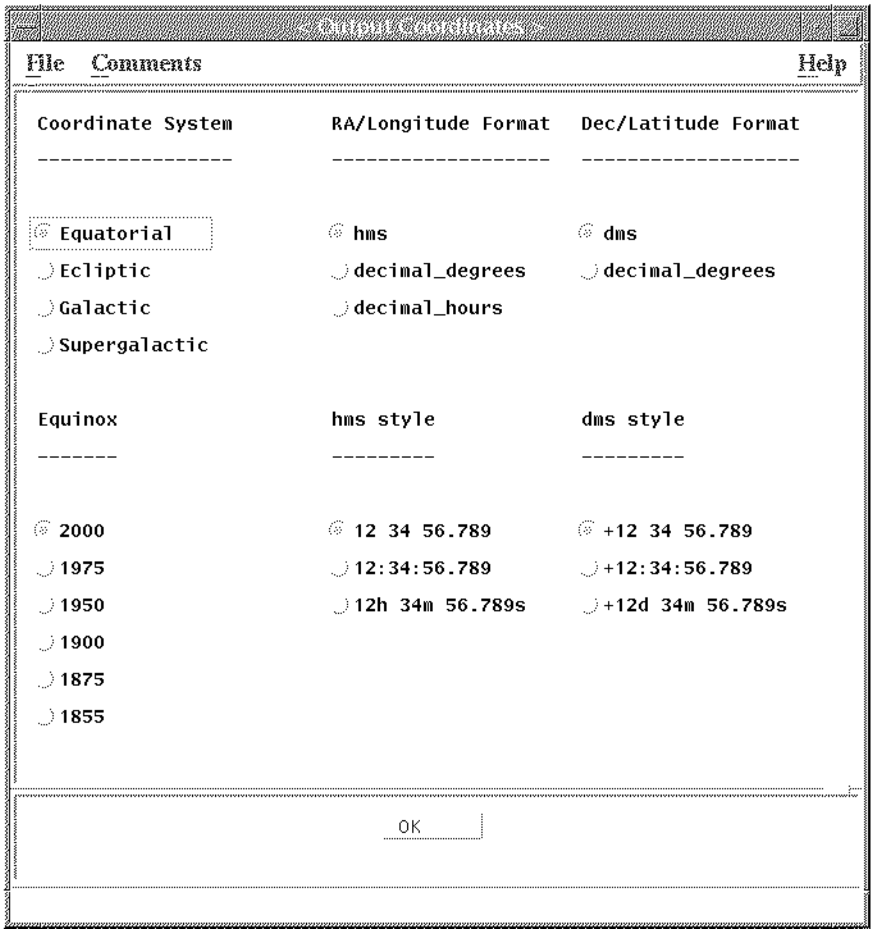

Figure 7.8: <Output Coordinates> Screen

This screen lets you modify the coordinate system, equinox, and format in which positional coordinates (RA, longitude, Dec, latitude) are displayed.

Field	Options
Coordinate System	Select Equatorial, Ecliptic, Galactic, or Supergalactic as the output coordinate system displayed on StarView's search results screens. This does not affect the input coordinates used on the search specification screens, which remain RA(2000) and Dec(2000).
Equinox	The coordinates will be precessed to the selected equinox before display. If you have selected Galactic as your coordinate system, the equinox is ignored.
RA/Longitude Format	You can select hours-minutes-seconds (hms), decimal degrees, or decimal hours as the format for RA and longitude fields.
Dec/Latitude Format	You can select degrees-minutes-seconds (dms) or decimal degrees as the format for Dec and latitude fields.

Table 7.7: Output Coordinates Options

The *input coordinates* on StarView's search specification screens (i.e., RA(2000) and Dec(2000)) are not affected by any of the above changes.

Date/Time Formats Screen

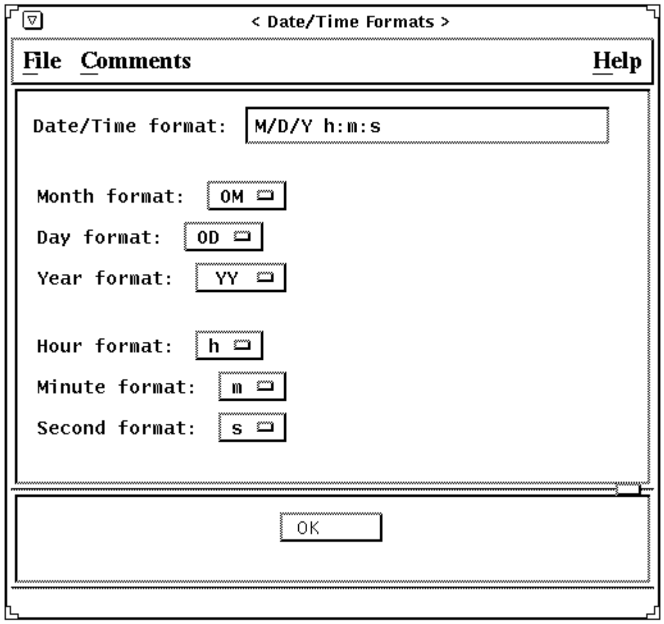

Figure 7.9: <Date/Time Formats> Screen

This screen lets you modify the format in which dates and times are displayed.

Field	Options
Date/Time format	Specify the order in which you would like the date and time components (e.g., month, year, hours) to be displayed.
Month format Day format Year format Hour format Minute format Second format	Select an option from the popup choice list that is displayed when you select one of these fields.

Table 7.8: Date and Time Format Options

Escaping to the Operating System

You can temporarily escape from StarView to the operating system to send e-mail, edit files, or do other non-StarView work. Follow the steps below.

1. Select **|Escape to OS|** from the **|File|** menu.

   A dialog box will appear, informing you that you are escaping to the operating system shell and that you must log out of the system shell to return to StarView.

2. Press **[OK]** on the dialog box.

   Your display will become blank, except for the system prompt.

3. Use the operating system to do your work.

4. Log out of the system shell to return to the current screen in StarView.

   Type `exit` on Unix systems, `logout` on VMS systems.

Working With the User Interface

This section explains various aspects of the StarView user interface: screens, menus, and fields. It also describes how to respond to StarView messages and how to save, open, and delete files.

StarView Screens

StarView screens let you search the HST catalog and request datasets from the HST archive. The following subsections describe the layout of StarView screens and explain how to move between items on a screen.

Understanding Screen Layout

StarView screens consist of several components. They are (explained below in order of appearance, from top to bottom):

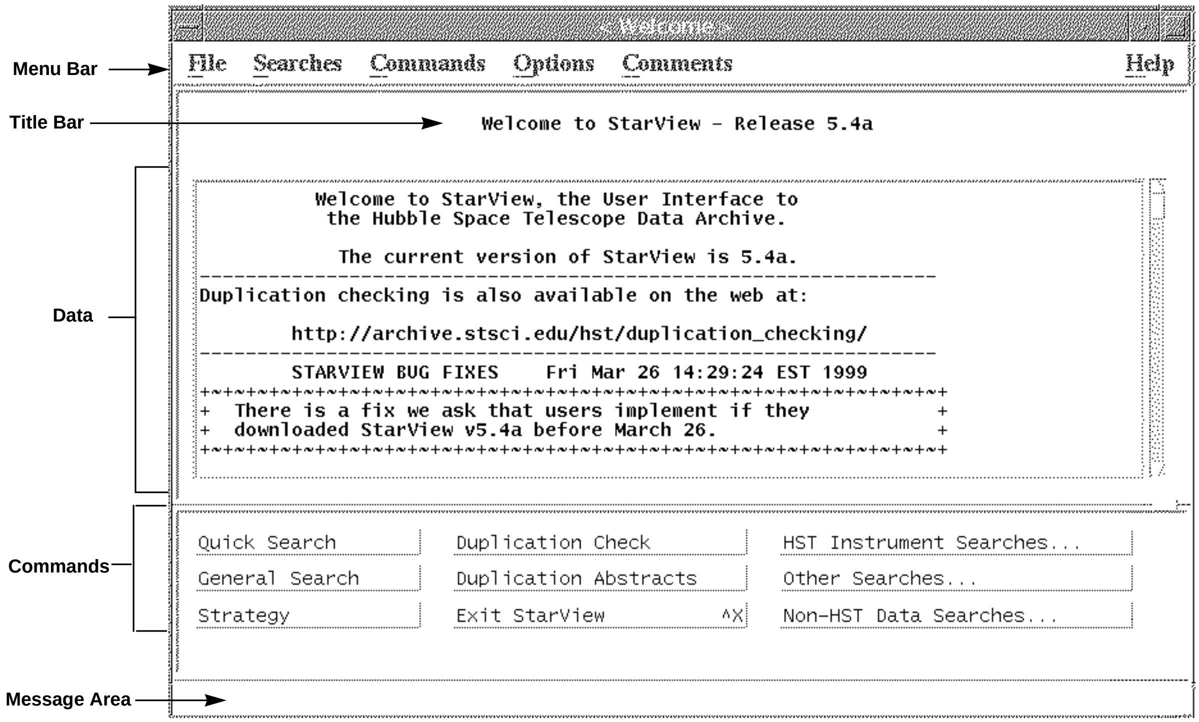

Figure 7.10: Screen Components

- Menu bar - contains the titles of the pulldown menus.
- Title bar - displays the title of a screen.
- Data area - normally, is the main display and user input area on a screen.
- Command area - is an optional area at the bottom of a screen that may contain pushbuttons for viewing search result records and for selecting major StarView functions. On search results screens, this area also displays the status of the current search.
- Message area - displays instructions and informative text.

More on Menus

For a basic explanation of StarView menus, see “Command Usage and Screen Interaction” on page 31. Menus display lists of functions for user selection. The menus and functions are screen-dependent. For example, the **|Constraint|** menu on a search screen lists functions for searching the HST catalog. The <Help> screen does not have a **|Constraint|** menu because you cannot search the catalog from this screen.

StarView has pulldown menus and submenus, which are explained below.

Pulldown Menus

The titles of pulldown menus appear across the top of a screen. Click on these names with the left mouse button to display the components of the menu, as shown in Figure 7.11.

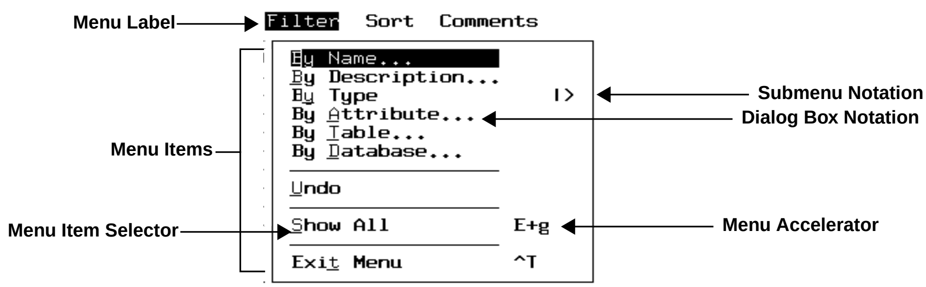

Figure 7.11: Menu Components

- Menu label - title of a menu.
- Menu items - functions that are displayed when a menu is selected.
- Menu item selector - single underlined letter in a menu item, used as a keyboard shortcut to move the cursor to that item.
- Menu accelerator - keyboard shortcut for executing a menu function, displayed to the right of some menu items.
- Dialog box notation - ellipsis (...) at the end of a menu item, indicating that a dialog box or another screen appears when the menu item is selected.
- Submenu notation - a bar and right angle bracket (| >) at the end of a menu item, indicating that a submenu appears when the menu item is selected.

To select an item with the mouse, click on the one you want. Selecting a menu item dismisses the pulldown menu, executes the desired function, and returns you to the current screen.

Submenus

Display a submenu by selecting a menu item with a " | >" symbol to the right of it. For example, selecting the **|Searches|** menu on the <Welcome> screen displays the following menu:

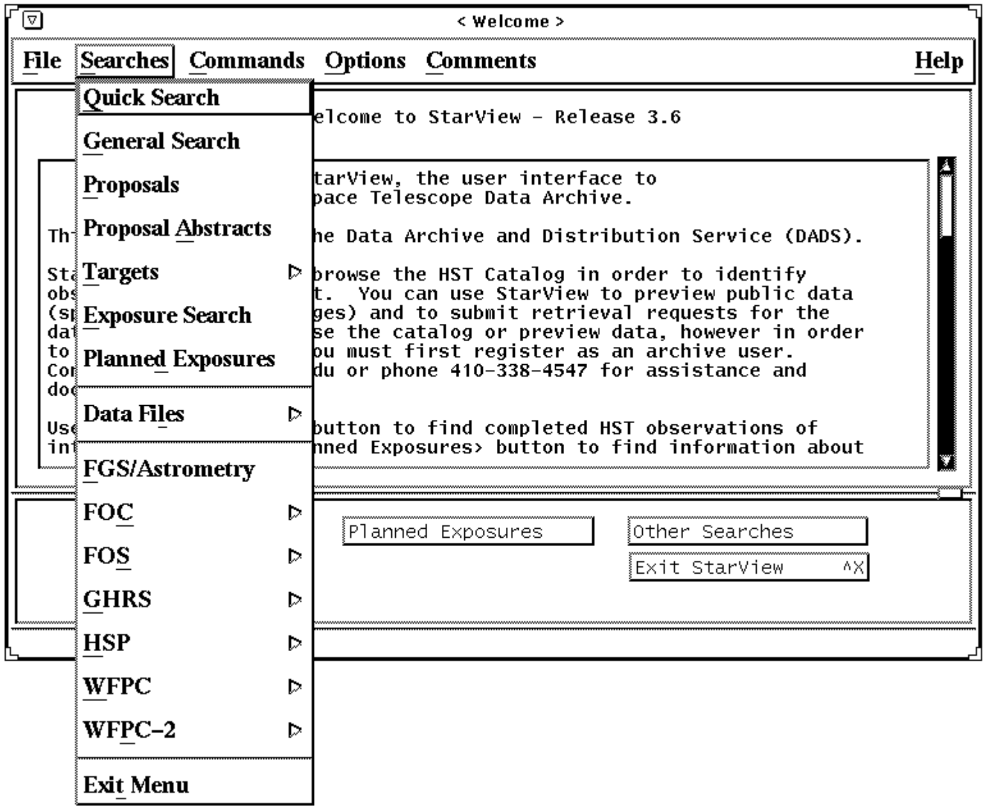

Figure 7.12: |Searches| Menu

Selecting **|Data Files|** on the **|Searches|** menu displays the following submenu:

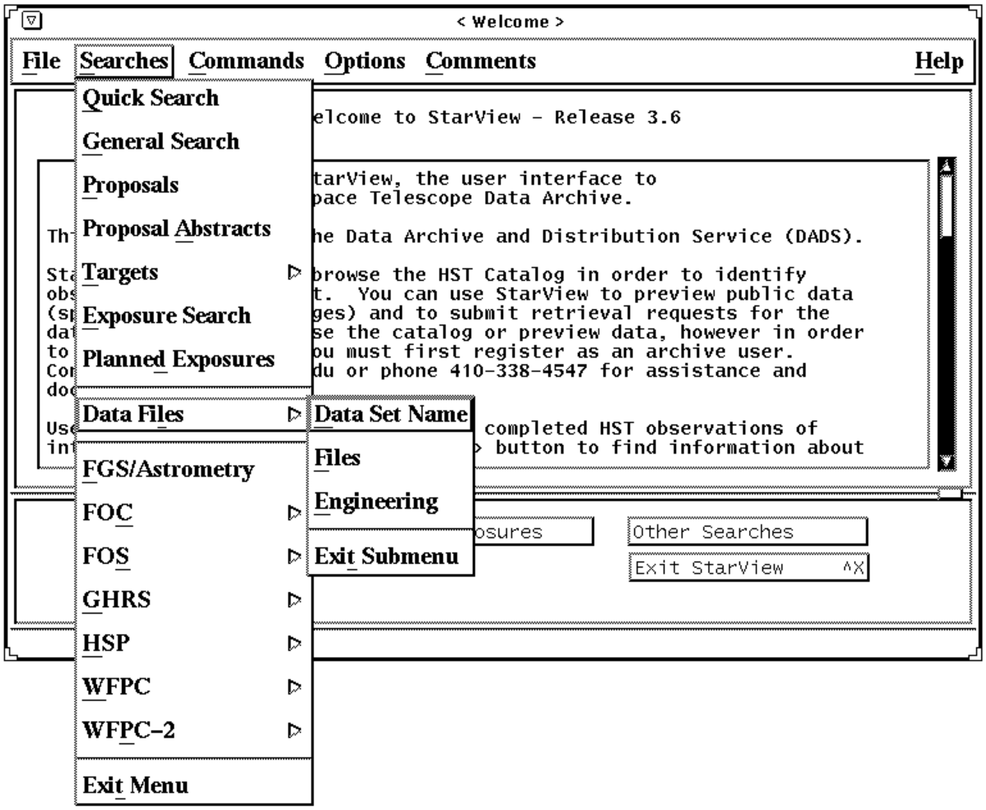

Figure 7.13: |Data Files| Submenu

Fields

Screens may contain fields in the data area and in the command area. Fields display text or let you enter values. Most fields have a field label, which characterizes the contents of the field. Field labels are mixed case, except labels that are ICD-19 keywords, such as “PXLCORR.”[1]

1. ICD-19 is the interface control document that the Space Telescope Science Institute (STScI) uses to correlate the contents of the HST catalog with the keywords in the data header files.

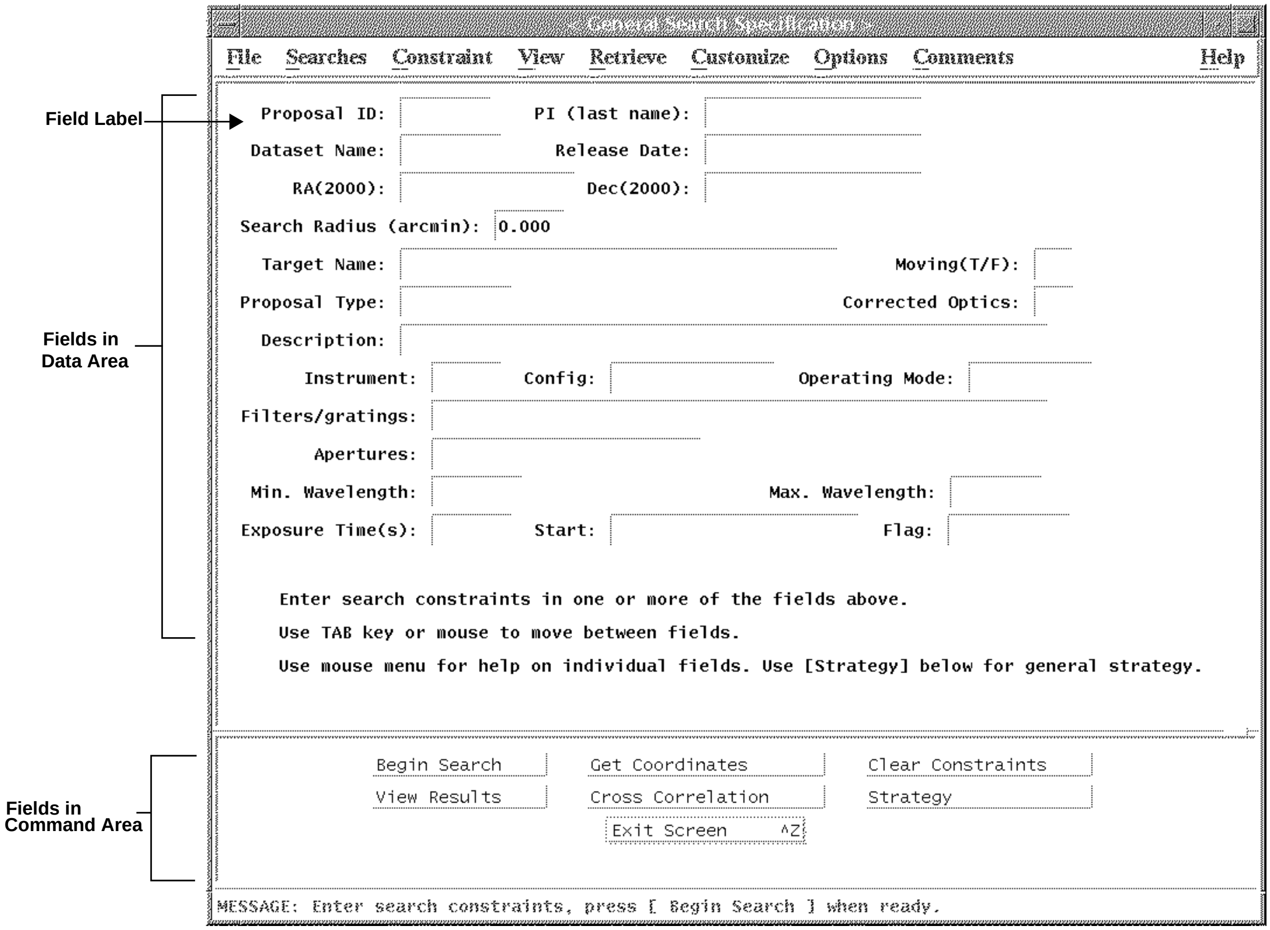

Figure 7.14: Types of Fields on a Screen

Fields can contain single or multiple lines of text. They can also display lists of values. Table fields appear on screens structured in a spreadsheet format, such as the <Table Format> screen.

StarView has three types of fields, as indicated in Table 7.9.

Type of Field	Characteristics	Restrictions	Example
Editable	Can be highlighted Can be modified Can be scrolled Can display help	None	Fields on a search specification screen in which you can enter values.)
Readonly	Can be highlighted Can be scrolled Can display help	Cannot be modified	Text area of the <Help> screen.
Unselectable	Can display status information	Cannot be highlighted Cannot be modified Cannot be scrolled Cannot display help	"Record m of n" field at the bottom of most search results screens

Table 7.9: Types of Fields

Using Special Fields

Screens may have special fields:

- Toggle fields
- Popup choice lists
- Radio fields

These fields are special because you enter values with minimal typing. They are used for data entry fields with a restricted selection of values.

Toggle Fields

Toggle fields simplify obtaining answers to questions with only two possible (Boolean) answers (for example, yes/no, true/false, or */blank).

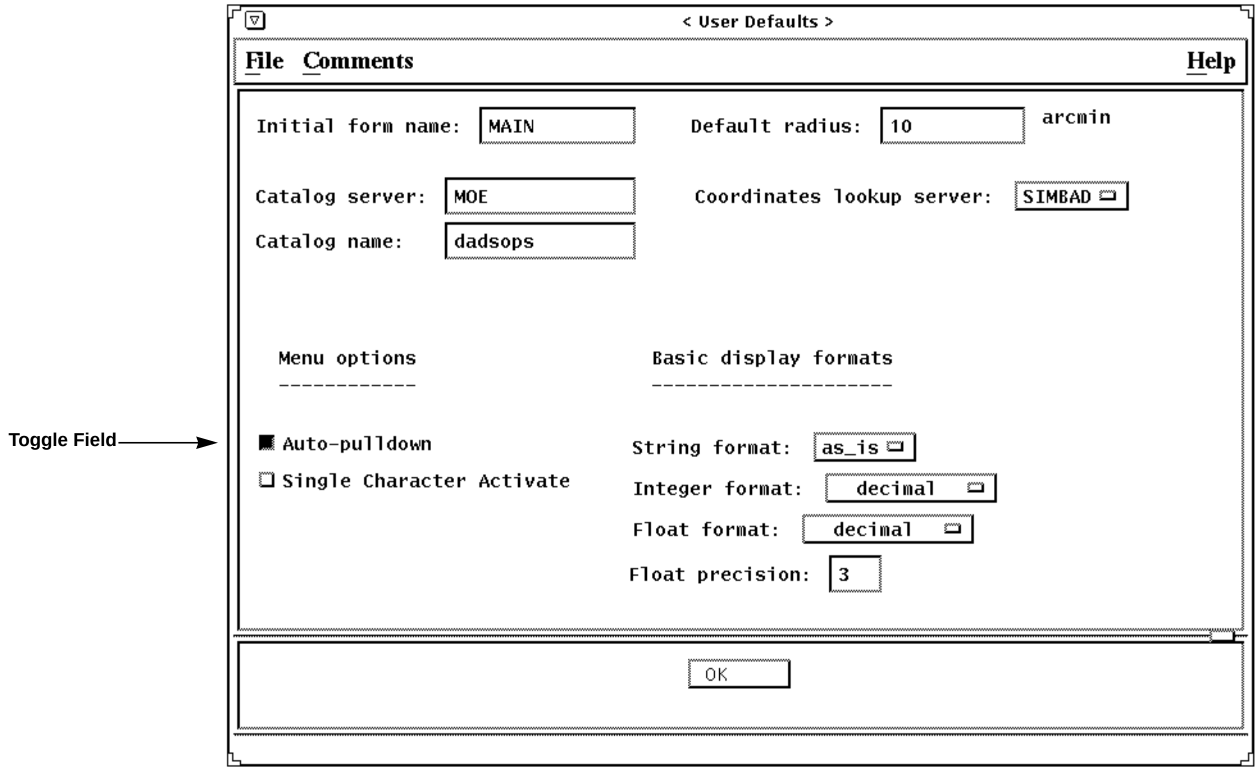

Figure 7.15: Toggle Field

Popup Choice Lists

Popup choice lists let you pick an item from a popup menu (choice list) that is then copied into the field. Therefore, you do not have to explicitly type a value in the field.

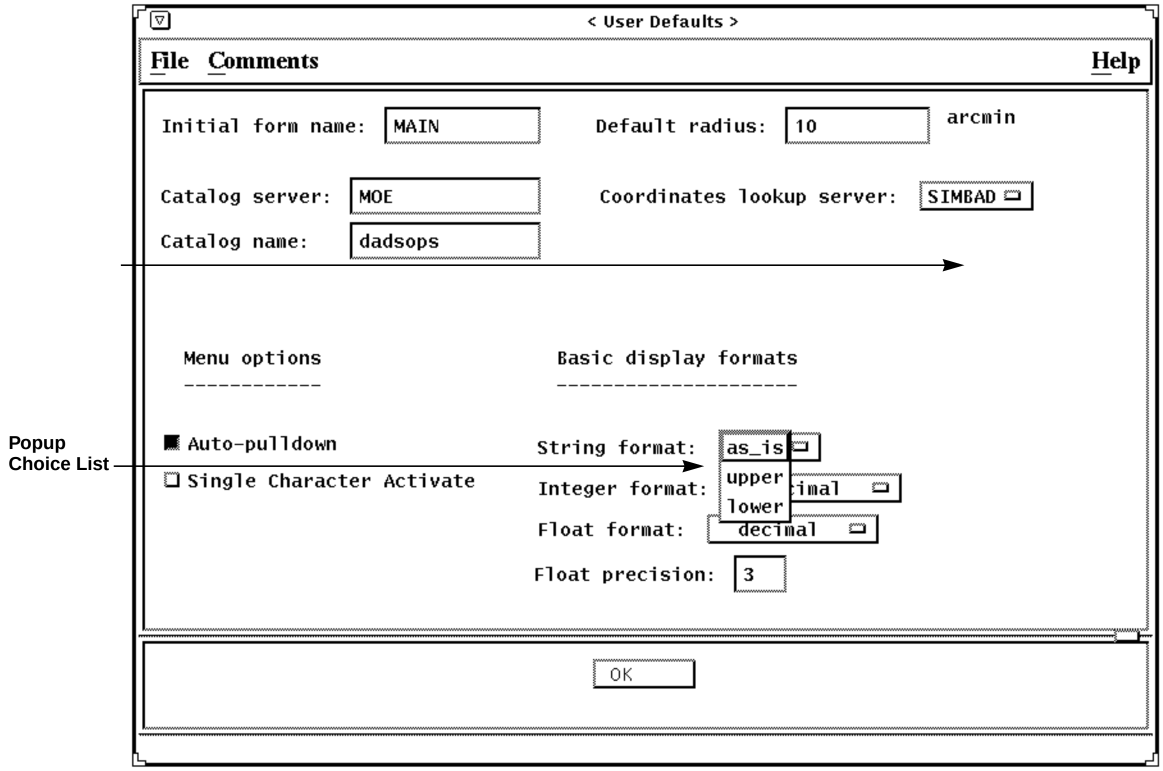

Figure 7.16: Popup Choice List

Radio Fields

Radio fields let you pick one of several mutually exclusive selections.

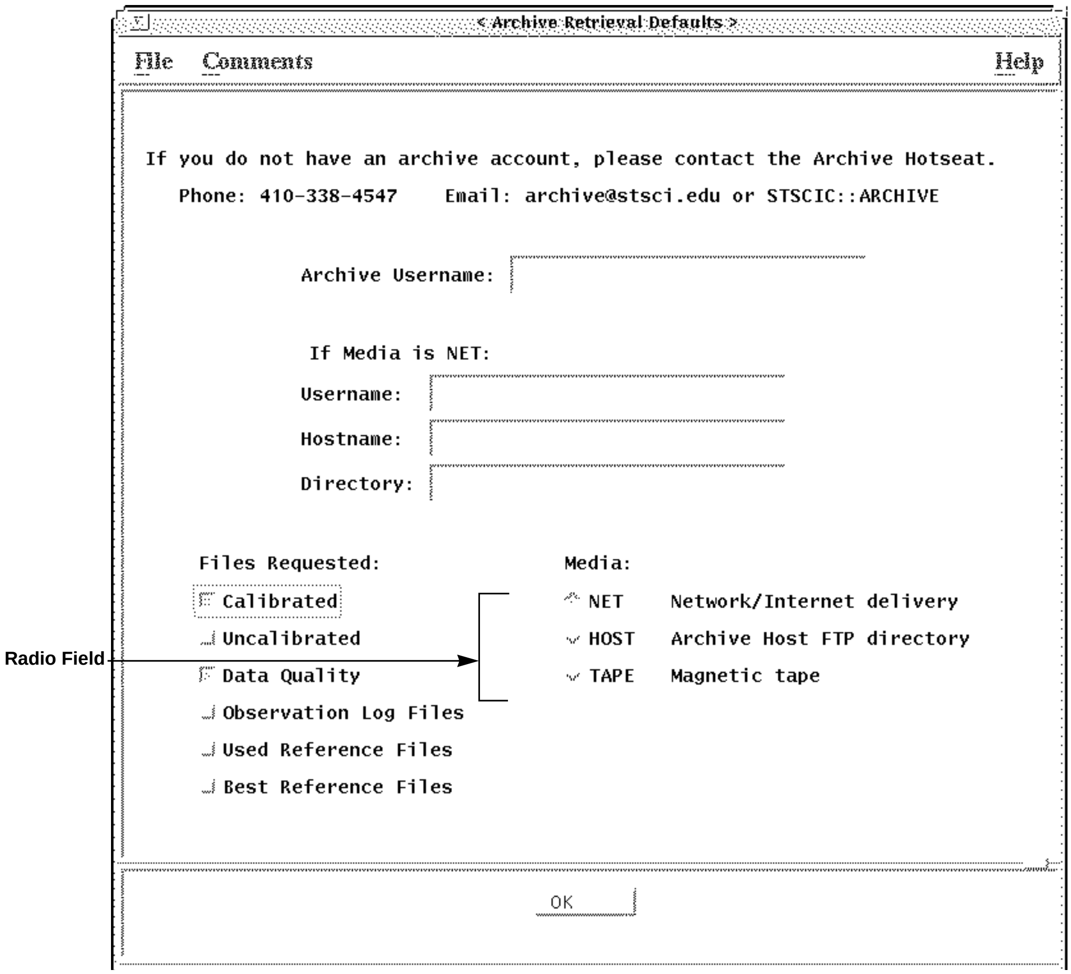

Figure 7.17: Radio Field

StarView Messages

While performing a task, you may accidentally enter an invalid value or attempt an inappropriate or invalid operation. Consequently, a message will appear either in the message area at the bottom of the screen or in a dialog box. The following subsections explain how to respond to messages in a dialog box.

Responding to Dialog Boxes

StarView has dialog boxes that display messages or request your input. Unlike screens, they do not contain menus. Instead, functions are executed using push buttons. You cannot proceed with an operation until you respond to a dialog box by choosing one of the displayed options by clicking on the appropriate button.

Some dialog boxes display a message that you need to read before continuing. After reading the message, press **[OK]**.

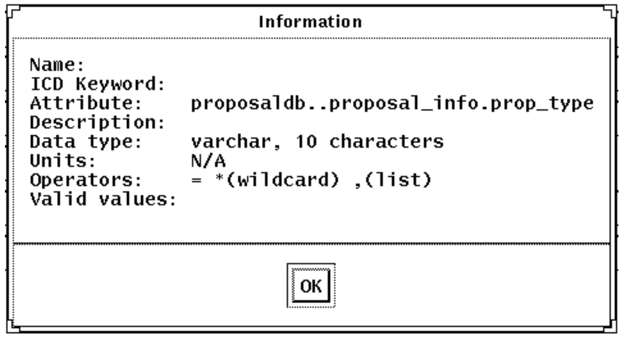

Figure 7.18: Informational Dialog Box

Some dialog boxes display questions. Respond to these dialog boxes by pressing **[Yes]** or **[No]**.

Some dialog boxes display messages that notify you of potential problems. Respond to these warnings by pressing **[OK]** or **[Cancel]**. Pressing **[OK]** continues a potentially destructive operation. Pressing **[Cancel]** instructs StarView to avoid (i.e., not perform) a potentially destructive operation.

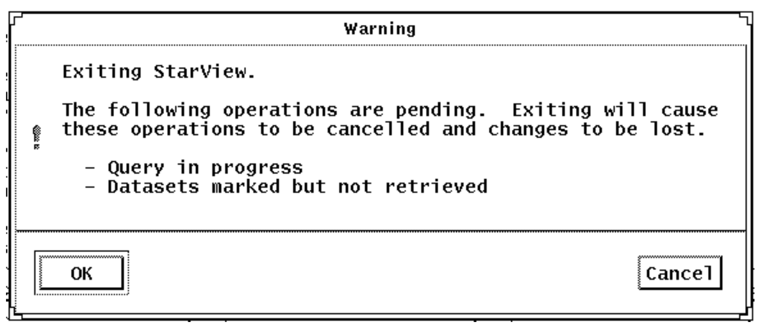

Figure 7.19: Warning Dialog Box

Some dialog boxes request your input. Respond to these messages by providing the input.

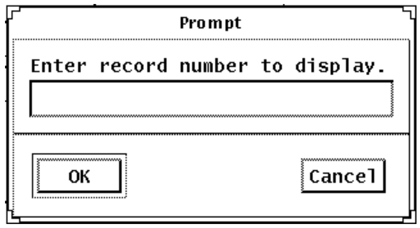

Figure 7.20: Prompt Dialog Box

Responding to the Error Dialog Box

The <Error> dialog box displays high-level error messages and additional, more detailed error messages in two vertically scrollable areas.

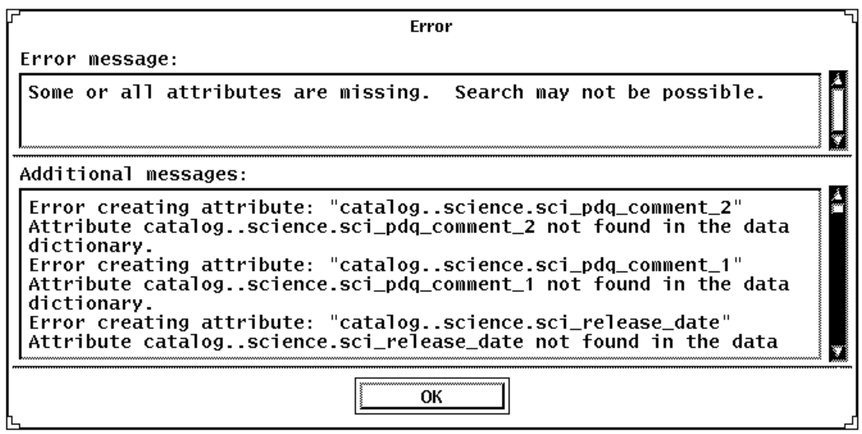

Figure 7.21: <Error> Dialog Box

Press **[OK]** to continue the current operation. If help is available for an error message, a **[Help]** pushbutton will appear on this dialog box.

Saving, Opening, and Deleting Files

While using StarView, you may want to save, open or delete query, retrieval request, or SQL files. The <File Selector> dialog box may be displayed while these functions are being performed.

Using the File Selector Dialog Box

The <File Selector> dialog box appears the first time that you save a file or when you open or delete a file. Use it to select a file. Press **[OK]** to execute the desired function.

If you have not previously saved a file, the <File Selector> dialog box will appear, prompting you for a file name. If you do not specify a file name extension, StarView will provide one. The default file name extensions are listed in Table 7.10.

.

Default Extension	File Type
`.db`	Table containing query result records
`.txt`	Exported ASCII table
`.fits`	Exported FITS (ASCII Tables Extension) table
`.qry`	Query
`.sql`	SQL

Table 7.10: Default File Name Extensions

The <File Selector> dialog box will not appear for subsequent saves of a file unless you decide to save a file under a new name. Instead, the existing file will be overwritten.

Filtering Files

You may want to filter files before selecting one. Filtering lets you display particular files in a particular directory. Directories and files are displayed in vertically scrollable fields. Scrolling lets you view items that are not visible.

To specify a directory:

- Move to a higher directory level by selecting the "../" symbol on Unix and "[-]" on VMS.
- Move to a lower level directory by selecting a directory.
- Rescan the current directory by selecting the "./" symbol on Unix and "[ ]" on VMS. Rescanning updates the directory list.

To filter the list of files:

1. Type a partial or complete file name in the "Filter" field. For partial file names, you may use the "*" wild card to match zero or more characters.

Wild cards let you filter multiple files with related names, without having to specify each file by its full, unique name. For example, if you type `.qry`, you will display all files with that extension.

2. Press Return.

Selecting a File

You can select a file either from the list of files or by typing a file name in the "Selection" field, or by clicking on the file name from the list of files displayed.

Dismissing the File Selector Dialog Box

Press **[OK]** to dismiss the <File Selector> dialog box, execute the desired function, and return to the current screen. Press **[Cancel]** to return to the current screen without executing a function.

On-The-Fly Calibration

The On-The-Fly Calibration (OTFC) service will provide archival researchers with the ‘‘best’’ calibrated data without requiring them to go through the complex recalibration process themselves. As described in “Tutorial: Retrieving Calibration Reference Files” on page 51, in fact, improved calibrations are possible with calibration files which are more recent than those used to calibrate the archived data in the first place. The OTFC Pipeline was constructed using the OPUS pipeline architecture and consists of a process that will accept raw datasets from DADS and return updated raw and calibrated datasets. Also, the OTFC system will update the headers of the raw data to reflect any changes in header keywords as well as updating calibration switches and reference file names. This new header information is used by the pipeline system to identify the appropriate calibration steps and reference files.

Currently only WFPC-2 and STIS data will be processed in the OTFC pipeline. Eventually OTFC will be applied to NICMOS and future instruments data.

OTFC requests can be made through a modified version of the standard <Retrieval Request - File Options> screen in StarView (page 186) or via the archive WWW interface, once OTFC is released externally (Fall 1999).

Dedicated StarView screens for each instrument, described in “On-The-Fly Calibration Screens” on page 185, can be used to extract more information about the recalibration, including the date the software was last changed and the latest date of any header keyword update for any dataset.

8 HST Catalog Screens

In This Chapter..

In this chapter you will find descriptions of all StarView screens: screens that are used to view the Hubble Space Telescope (HST) catalog, retrieve data, get help, navigate around StarView, and manipulate StarView operations. The screens are presented in groups, organized according to the general class of actions that you would take and to the information displayed on the screens in each group. The screens within each group are presented alphabetically by screen name.

Refer to Figure 8.1 for assistance in locating a particular screen description. Figure 8.1 presents a schematic view of the groups of StarView screens, in the order that they are presented in this chapter. Screen names are listed in each box.

The External Data Sets screens are not described here as they are self-explanatory. Note also that retrieval of IUE data can *only* be done via the MAST WWW interface (see page 25; FIRST and DSS retrievals can be done either way), so users are advised to use that interface to search the IUE archive.

Figure 8.1: StarView Screens

Proposal Screens

StarView provides several proposal screens that let you look at the pre-observation proposal-level data stored in the HST catalog. For example, the screens provide information about proposers, proposal titles, proposal abstracts, proposed targets (including a special screen just for solar system targets), and proposed observations (including instrument parameters and exposure times). The StarView proposal screens are presented and described in this section.

These screens primarily display proposal-level information; that is, information that was provided by the observer during Phases I and II of the proposal submission process, although some fields are updated when exposures are taken. The <Planned Exposure> and <Solar System Target> screens are particularly useful for obtaining information about HST observations that have been approved for execution, but that have not yet been taken. Obviously, you cannot retrieve data for an observation that has not yet been taken. Hence, the corresponding StarView results screens in this group do not include dataset names or dataset marking/retrieval capabilities.

The <Duplication Check> and <Duplication Abstract> screens were designed to help observers determine whether their proposed observations conflict with previously accepted GO or GTO programs.

<Proposal> Screen

You can use this screen to initiate searches of proposal-specific information in the HST catalog. This screen contains only very general proposal information, with only one catalog entry per proposal. Since this screen does not provide exposure-level information about HST observations, the corresponding results screen does not include dataset name or dataset marking/retrieval capabilities.

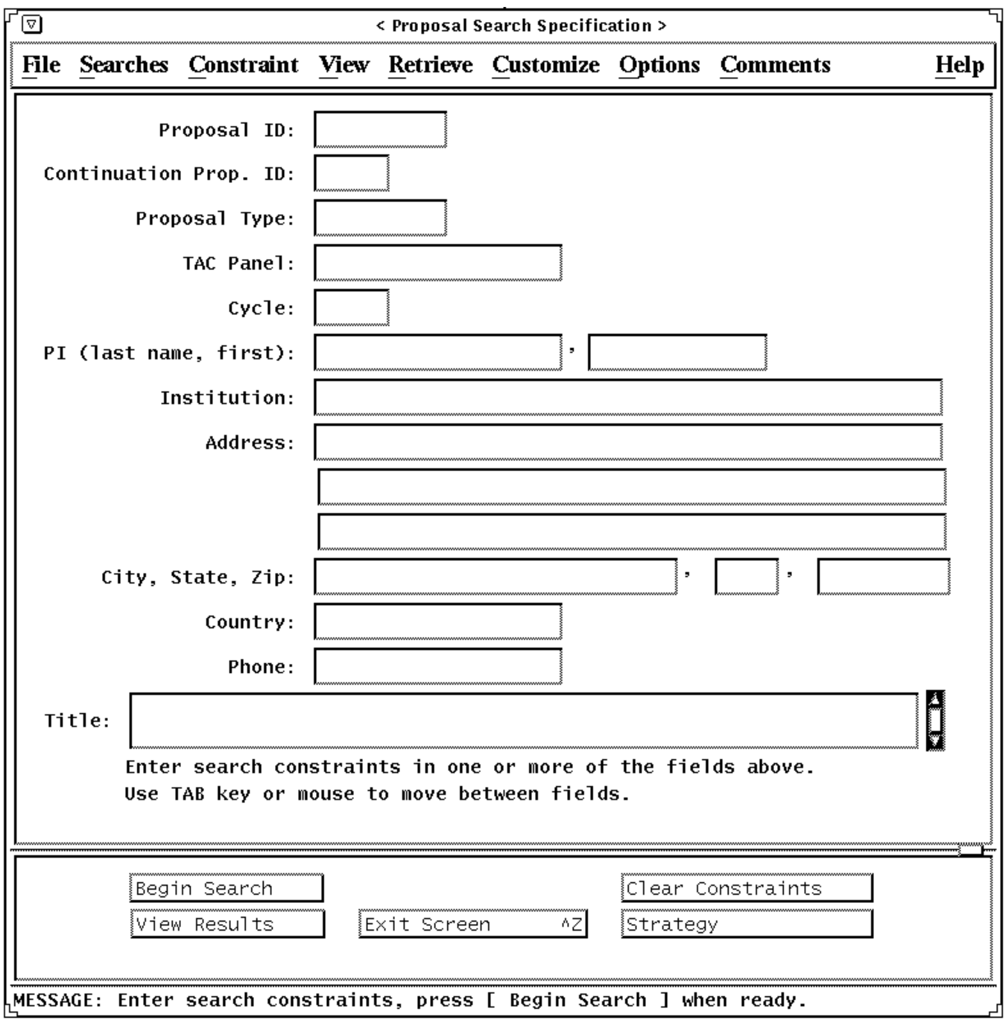

Figure 8.2: <Proposal> Screen

<Proposal Abstract> Screen

You can use this screen to initiate searches of proposal abstracts in the HST catalog. This screen contains only very general proposal information, with only one catalog entry per proposal. Since this screen does not provide exposure-level information about HST observations, the corresponding results screen does not include dataset name or dataset marking/retrieval capabilities.

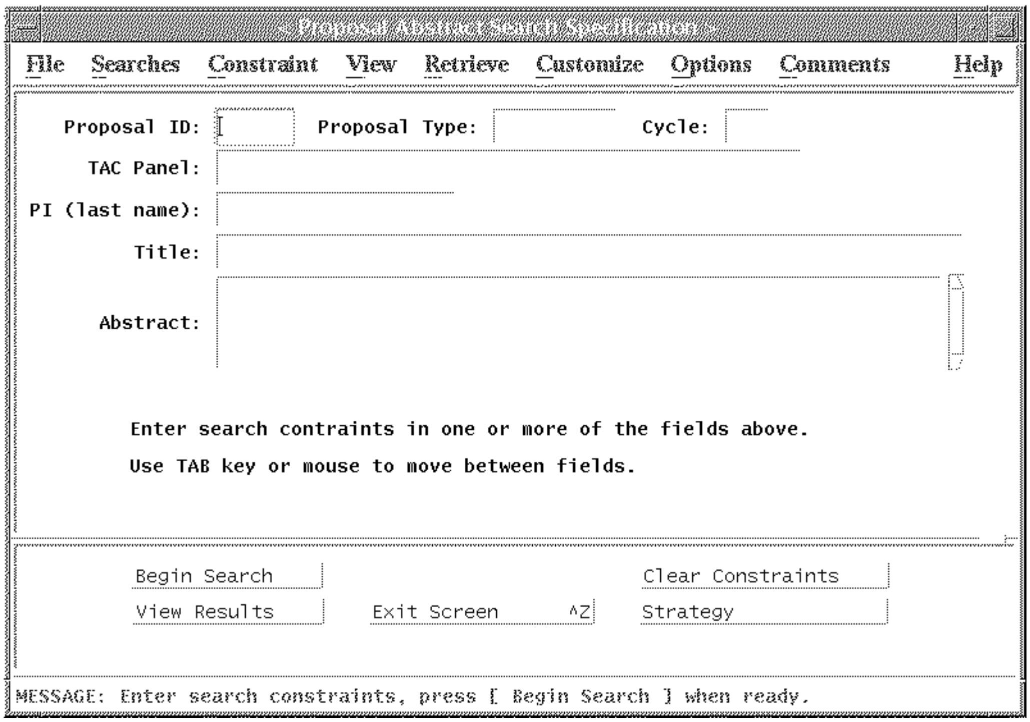

Figure 8.3: <Proposal Abstract> Screen

<Planned Exposure> Screen

The <Planned Exposure> screen can be used to check on the schedule dates and completion status of an HST proposal or to search for planned HST observations of a given target. This screen looks at tables made from the proposal entry and scheduling database at STScI. Thus, this screen provides information on all planned observations which have been through Phase II processing (including carryover proposals).

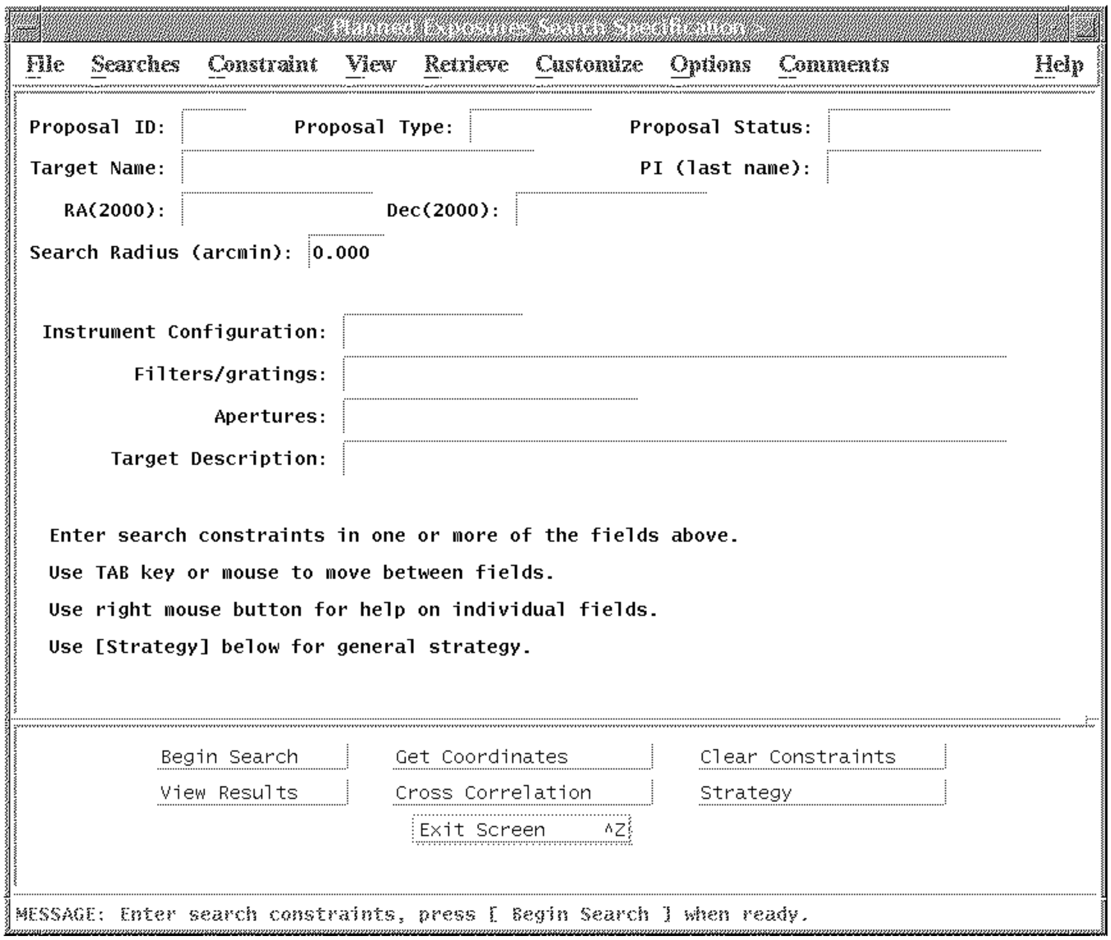

Figure 8.4: <Planned Exposure> Screen

<Solar System Target> Screen

You can use this screen to initiate searches for proposed and exposed solar system target observations in the HST catalog. This includes planned observations which have been through Phase II processing, as well as previous exposures.

Note that there are three levels of position keywords for solar system targets: with respect to the sun, with respect to the parent body, and with respect to the target itself.

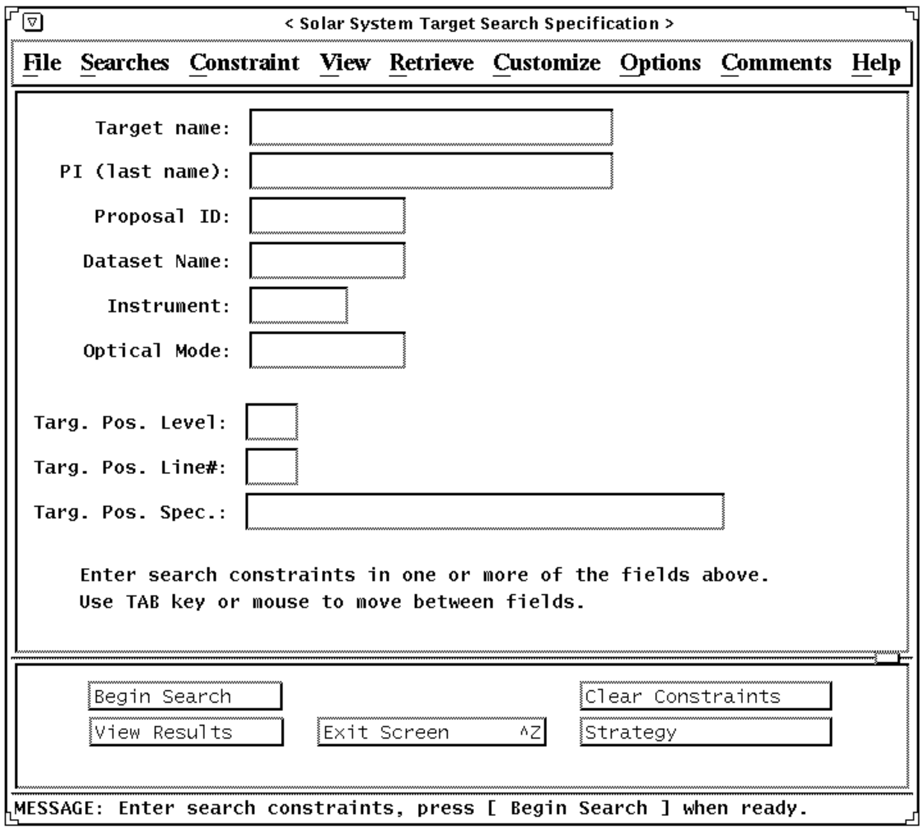

Figure 8.5: <Solar System Target> Screen

<Duplication Check> Screen

This screen was designed to facilitate duplication checking by proposers who are writing their Phase I, or initial, proposals to obtain HST observations. An observation is defined as duplicating a previous one if it is on the same astronomical target, with the same or similar instruments, a similar instrument mode, and a similar spectral range. Proposers must check their proposed observations and identify them and justify them in the Phase I proposal.

A duplication check for fixed targets MUST be done with coordinates. *A target name search is insufficient to reveal duplications.* The target names are entered by the observer, and therefore can vary subtly between proposers. If a proposer only has target names, the **[Get Coordinates]** button on this screen enables them to obtain target coordinates from NED or SIMBAD. Cross-correlation searches from ASCII coordinate lists can also be done with the Duplication screen. (See “Cross Correlation” on page 95.)

If a proposer identifies a conflict and accurately describes it to the Telescope Allocation Committee (TAC), then if the TAC decides that the observations are needed nevertheless, the TAC’s judgement will hold. However, if the conflict is not discussed and it is revealed later to be a conflict that the proposer should have included, then under normal circumstances that observation will be disallowed and the orbits taken away. A complete discussion of duplications or conflicts is beyond the scope of this manual. Proposers should consult the current Call for Proposals and Instructions for Phase I Proposal Preparation for the most up to date guidelines.

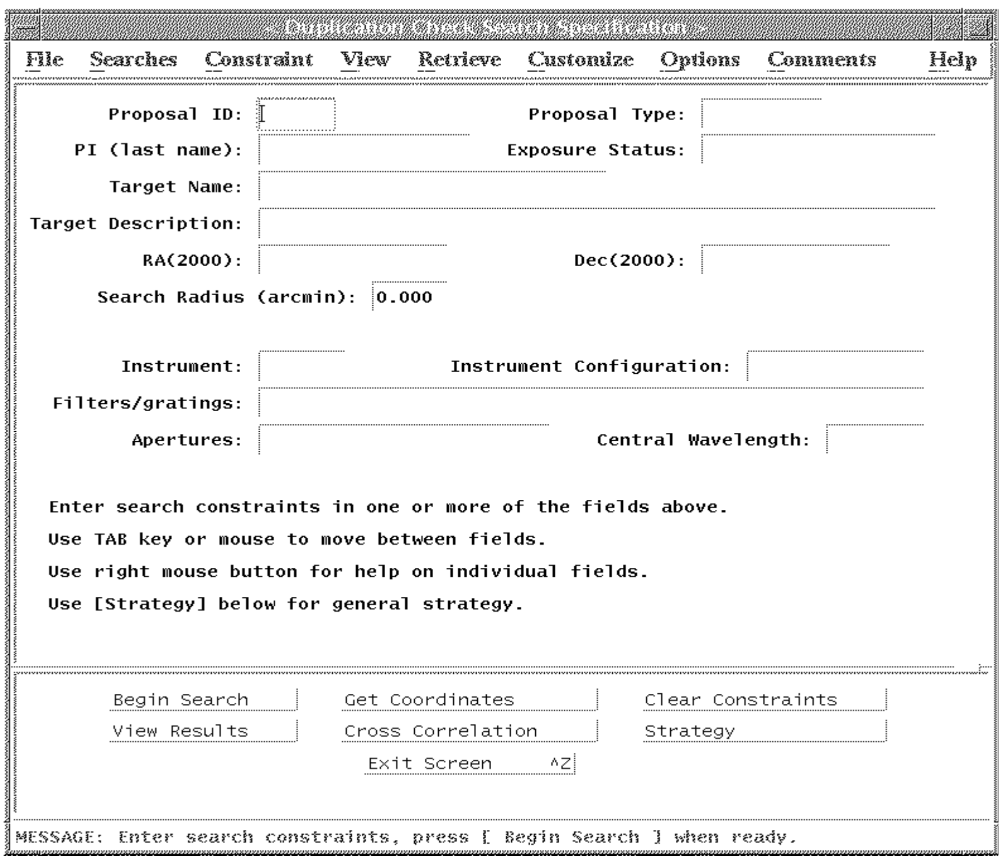

Figure 8.6: Duplication Check Screen

<Duplication Abstract> Screen

This screen, accessed via the Searches menu, was designed to help HST proposers do the required duplication checking. This screen provides supplementary information to that available from the Duplication Check screen. In particular, this screen enables proposers to search the abstract and proposal title for words relevant to scientific content, or to determine what sorts of proposals were evaluated by a certain panel in the previous cycle when trying to decide which TAC panel to suggest for proposal evaluation

Recall that the abstract is stored as a single text string, and that abstract searches are case sensitive. Searching the abstract thoroughly requires some special strategies, such as embedding all strings in wild-card characters, and listing all possible versions of a relevant string. For example, the string "*Quasar*,*quasar*,*QSO*,*AGN*,*Active gal*,*active gal*,*Active Gal*" will turn up more records than any of these strings entered singly.

.

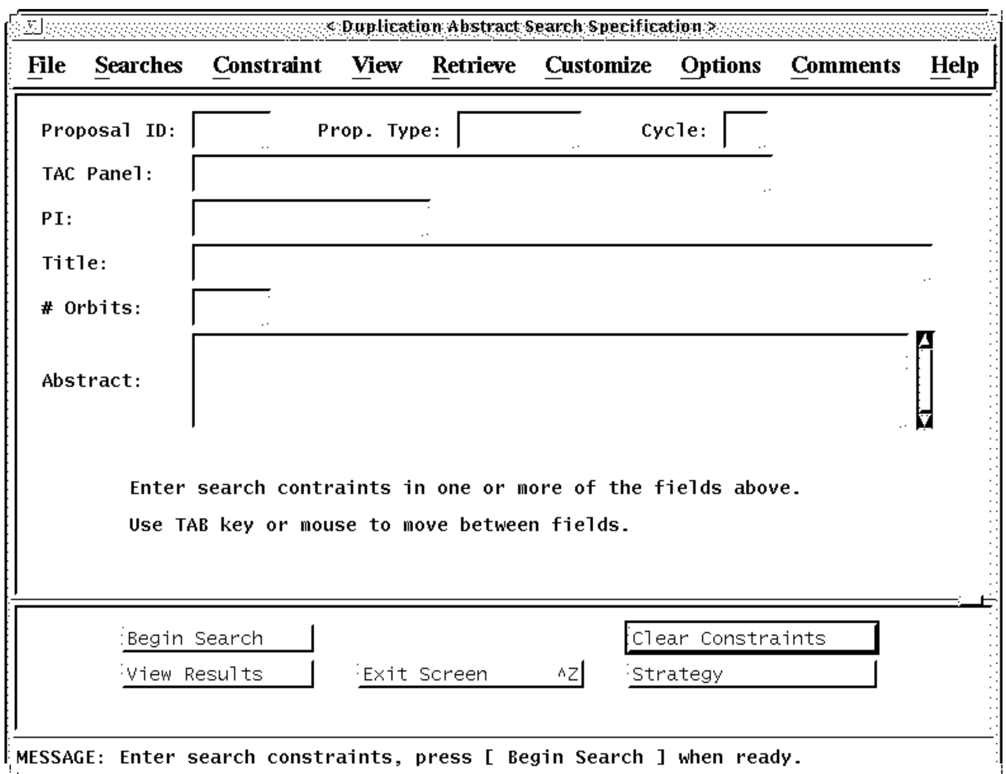

Figure 8.7: Duplication Abstract Screen

Observation Screens

StarView provides several observation screens that let you view the full catalog of completed HST observations. These screens are the heart of StarView. They let you see what observations have been done and then provide you with the option of retrieving the corresponding data from the HST archive. For example, you can conduct straightforward catalog searches on the <Quick Search> screen, use the <General> screen to conduct searches with lots of constraints, or use the <Exposure Search> and <Target Search> screens to conduct specialized searches based on proposal-level exposure and target information, respectively. Refer to Chapter 5 for search strategies that may be helpful in finding observations of specific targets in the HST catalog.

You cannot use these screens to find Fine Guidance Sensor (FGS)/astrometry observations. Those data files do not belong to the CAL archive class, and StarView results screens that include the “Release date” field are constrained to look at CAL class files in order to display on the screen the most scientifically meaningful release date (i.e., that for the actual science data files in the dataset). To view FGS/astrometry observation records and to retrieve the corresponding data files (archive class = AST; see Chapter 9), you will have to use the <FGS/Astrometry> instrument screen (see page 153).

The <Observatory Monitoring> Screen allows you to view the keywords in the Observatory Monitoring System (OMS) files. These files, generated since January, 1994, contain information about the orientation of the telescope and the jitter information recorded during observations.

<Exposure Search> Screen

You can use this screen to initiate searches of the HST catalog that correlate exposure-level information from the proposals with that from the actual observations. It is especially helpful to use this screen to search directly for specifically planned exposures according to either their Proposal Entry Processor System (PEPSI) line numbers (or exposure numbers) in the original proposal, or their PEPSI proposal sequence names (if any), or the IDs of their planned observation sets (obsets). In this way, you can correlate a collection of proposed observations with a collection of completed exposures. You can also use these obsets and sequences to find exposures that were taken essentially at the same time or under the same spacecraft conditions, or as part of a complete scientifically-defined set of observations.

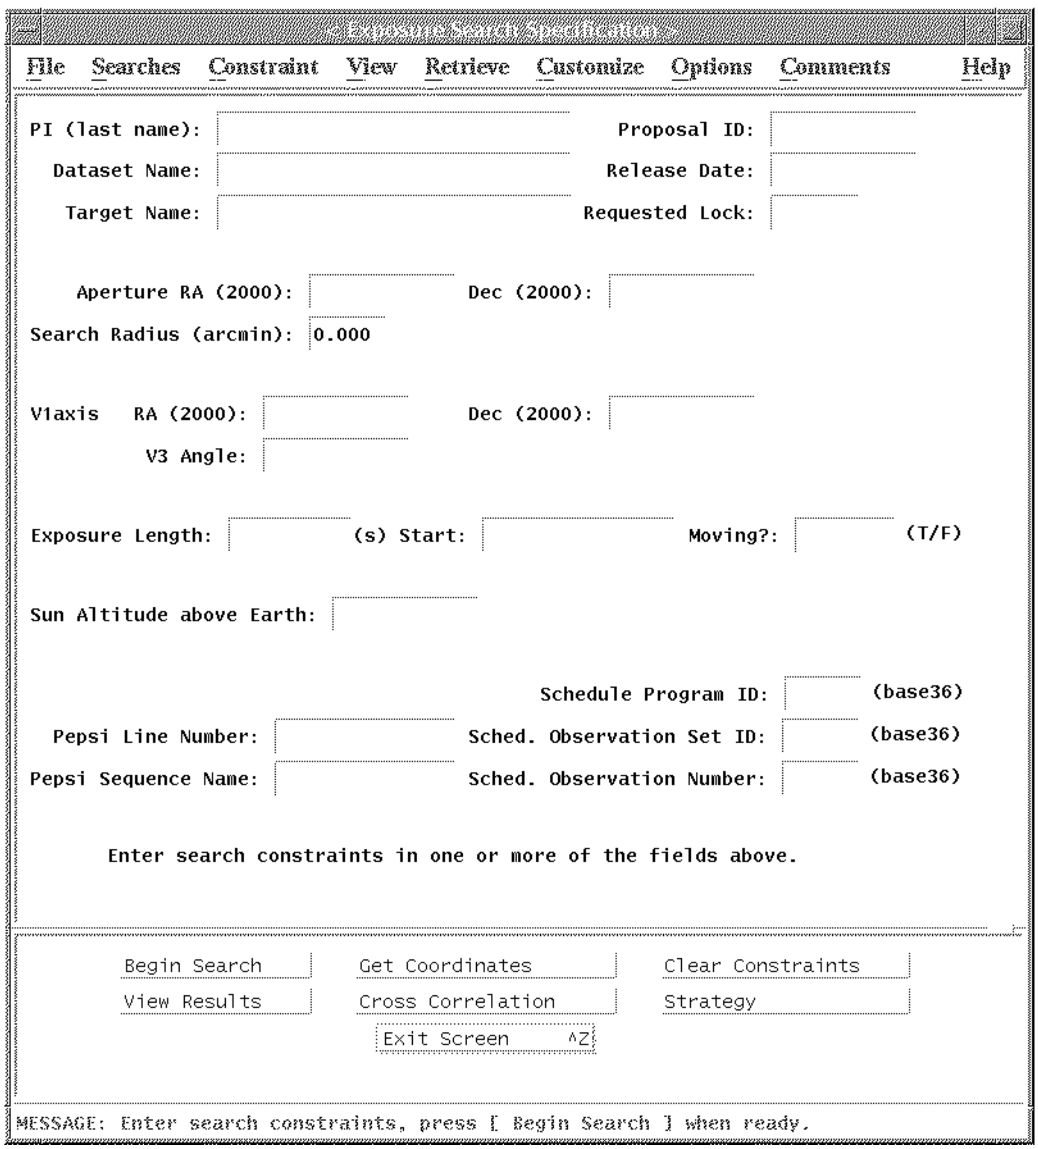

Figure 8.8: <Exposure Search> Screen

<General> Screen

You can use this screen to initiate a broad variety of informational searches of the HST catalog. This is the most general archive exposure search screen. The <General Search Results> screen includes the same fields as the <Quick Search Results> screen, but you can constrain any combination of those fields here. You can constrain only the most basic archival search fields on the <Quick Search Specification> screen (see page 149).

The results screen also includes the data quality comments from the Observation Support / Post Observation Data Processing System (OPUS, formerly known as PODPS). These comments (along with the exposure flag) may help you to assess the quality of the data in a given HST exposure before you ask to retrieve it. See the discussion that begins on page 74.

Chapter 5 describes helpful search strategies to find executed observations of specific targets in the HST catalog.

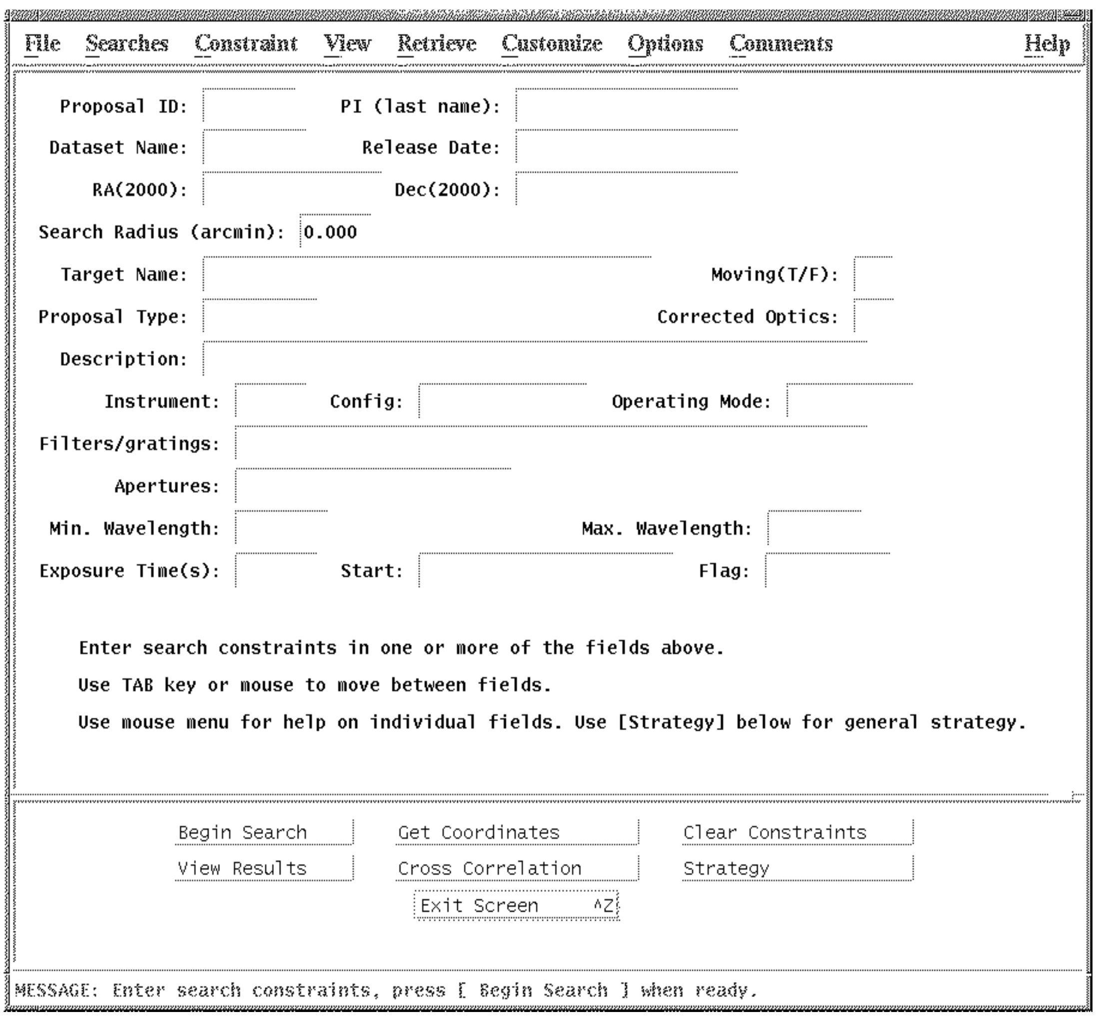

Figure 8.9: <General> Screen

<Quick Search> Screen

You can use this screen to initiate the most common types of informational searches of the HST catalog. The screen includes only a few simple fields by which you can constrain your catalog search. The <Quick Search Results> screen, however, includes the same comprehensive set of fields as the <General Search Results> screen (see page 148). Refer to Chapter 5 for search strategies that may be helpful in finding executed observations of specific targets in the HST catalog.

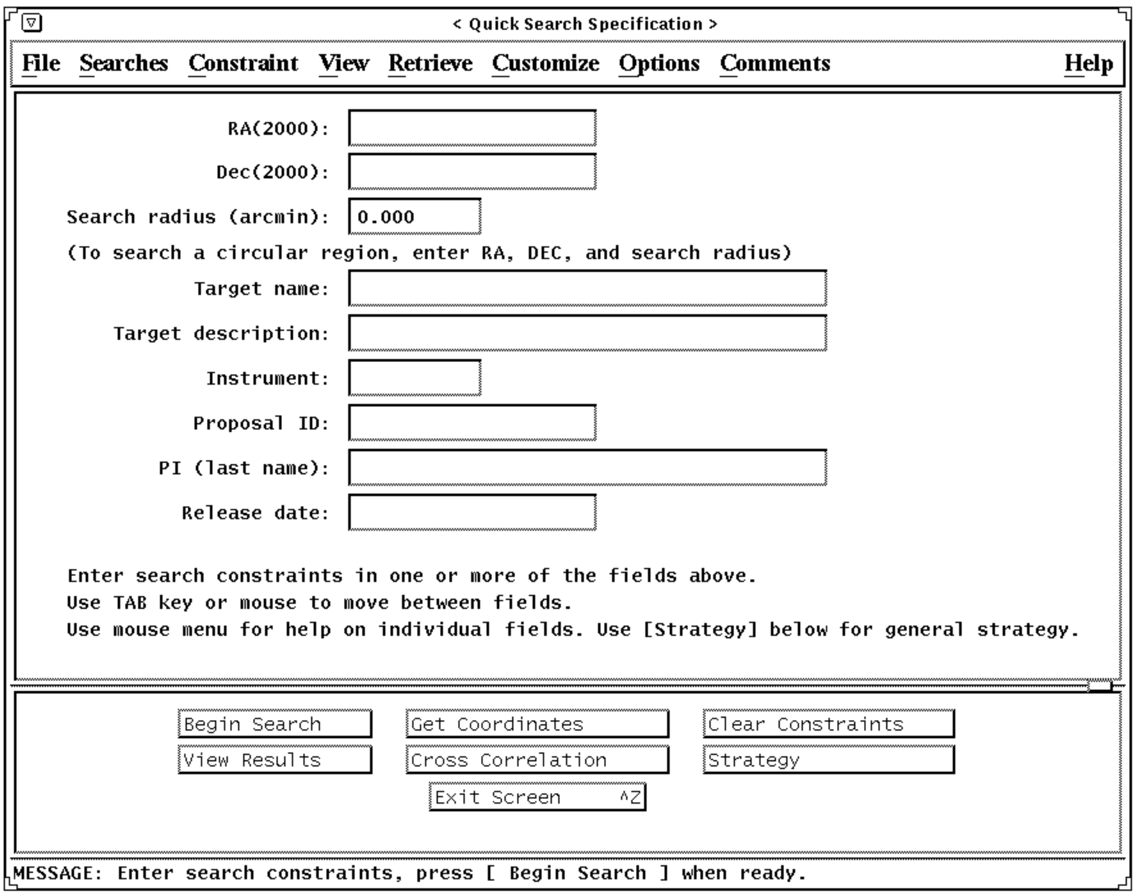

Figure 8.10: <Quick Search> Screen

<Fixed Target Search> Screen

You can use this screen to initiate searches of target-related information in the HST catalog. You can find observations of specific targets using either proposal-level or exposure-level search criteria (or some combination of the two).

Refer to Chapter 5 for helpful search strategies to find executed observations of specific targets in the HST catalog. Refer especially to Table 5.3 through Table 5.12 for comprehensive lists of the allowed target categories and descriptive keywords.

If you are specifically interested in solar system targets, then you can search the list of proposed solar system observations for specific targets using the <Solar System Target> screen. Then use the target names or proposal ID's that you find there to constrain your exposure search on this screen or on one of the other observation screens described in the preceding pages.

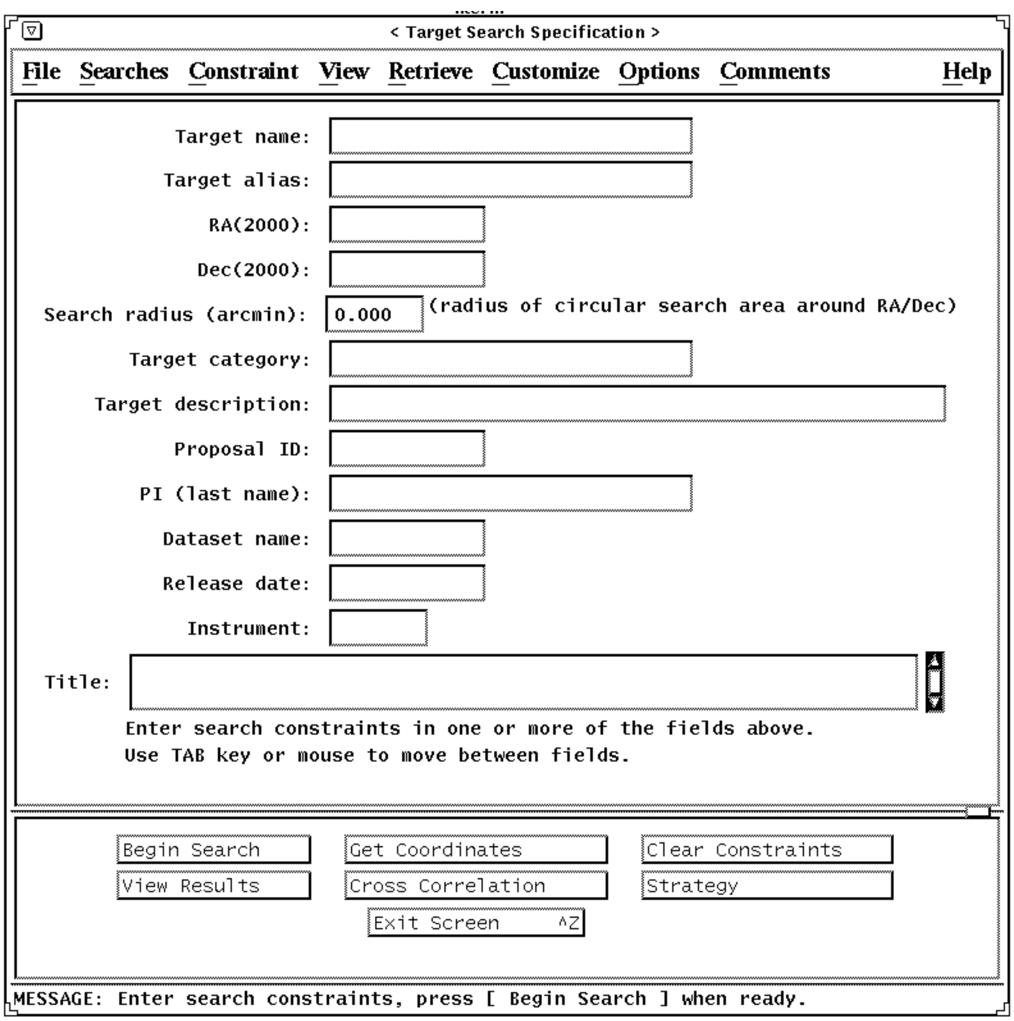

Figure 8.11: <Target Search> Screen

Observatory Monitoring Search Screen

The <Observatory Monitoring Search> screen allows users to search for observations based on telescope orientation criteria and it allows users to view and retrieve jitter information.

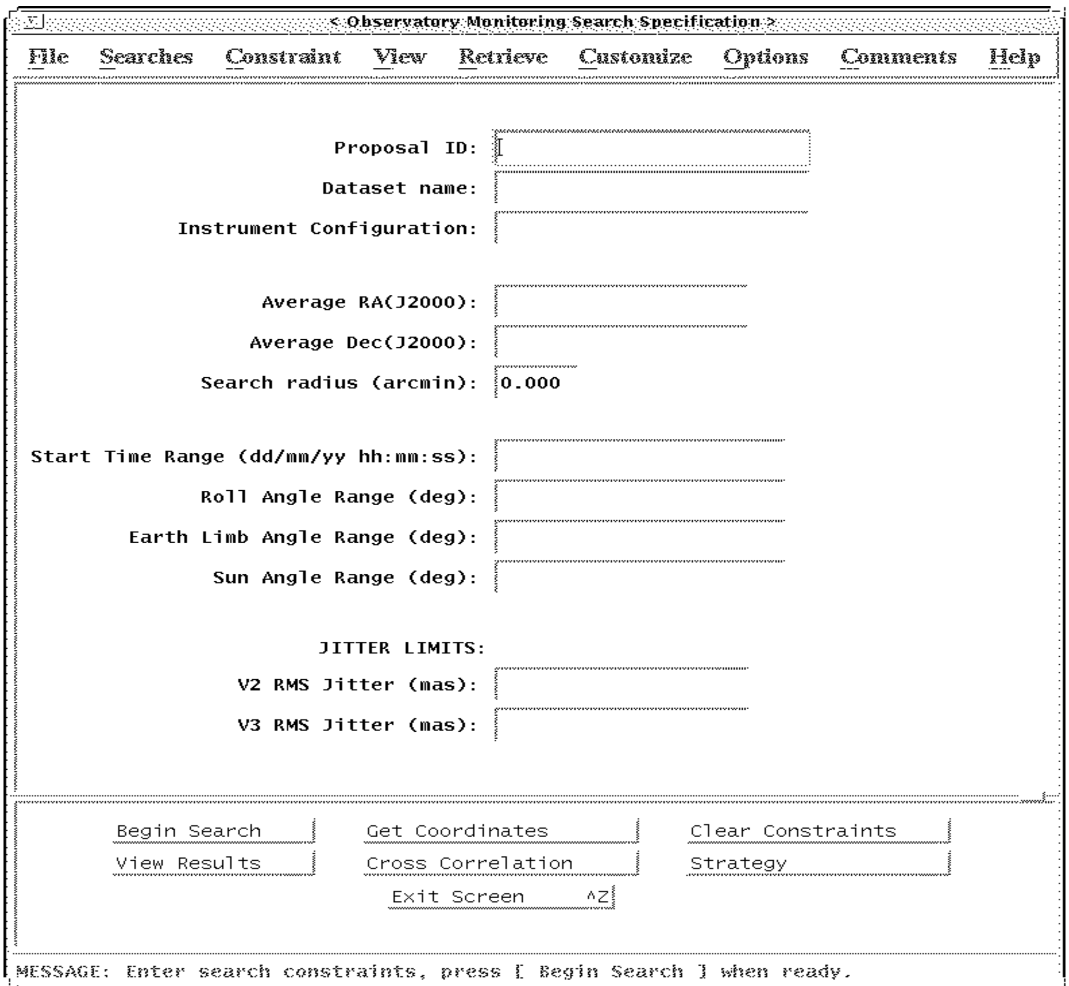

Figure 8.12: Observatory Monitoring Search Screen

Instrument Screens

StarView provides several instrument screens that let you view some of the instrument-specific exposure information stored in the HST catalog, all of them accessible from the <HST Instrument Searches> screen. There is one screen for each scientific instrument, and each contains parameters that are particular to that instrument (e.g., special configurations, set-up parameters, operating modes, and readout parameters). For example, you can use these screens to find all observations that were made using parameters equal to those of a particular observation that you may wish to retrieve. This could be very beneficial in analyzing and interpreting data obtained with special instrument configurations.

In addition to their instrument-specific fields, the StarView instrument screens all have a basic set of fields in common. Any combination of these fields can be used to constrain searches of the HST catalog. The common fields include:

- PI name
- Proposal ID
- Dataset name
- Release date
- Target name
- FGS lock (see page 77)
- Target position
- HST orientation (V1, V3 angles)
- Exposure parameters (duration, start time, and exposure flag (see Table 5.13))

However, it is the set of additional instrument-specific fields that distinguishes the nine instrument screens from one another (and from other StarView search screens) and that therefore makes each of these screens independently useful for instrument-unique catalog searches. These extra fields are described below as each separate screen is presented. Please refer to the individual Instrument Handbooks for a detailed description of the various fields.

<FGS/Astrometry> Screen

You can use this screen to search the HST catalog for detailed instrument-specific exposure information related to FGS/astrometry observations. In addition to the exposure information that is common to all of the instrument screens (page 152), you can use this screen to find:

- The specific target ID (which is derived from proposal ID plus target number)
- Which FGS was used for the astrometry observation
- Which FGS filter was used for the observation
- The magnitude of the observed target
- The telemetry format of the astrometry data
- The astrometry processing mode

You have to use this screen to view FGS/astrometry observation records in StarView and to retrieve the corresponding data files (archive class = AST; see Chapter 9). Since those data files do not belong to the CAL archive class, they cannot be viewed or marked on the usual StarView results screens. The typical StarView result screens that include the “Release date” field are constrained to look at CAL class files in order to display on the screen the most scientifically meaningful release date (i.e., that for the actual science data files in the dataset).

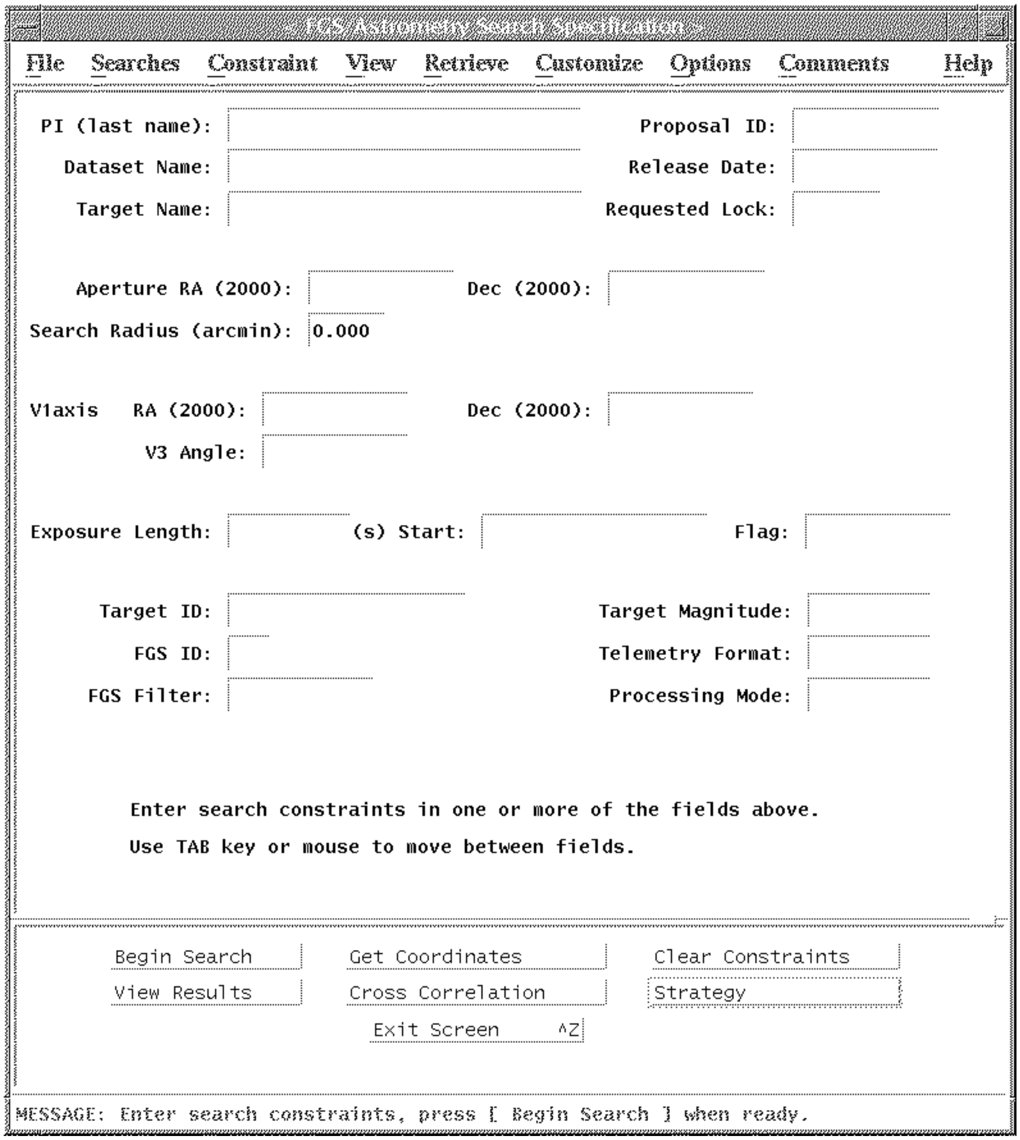

Figure 8.13: <FGS/Astrometry> Screen

<FOC> Screen

You can use this screen to search the HST catalog for detailed instrument-specific exposure information related to Faint Object Camera (FOC) observations. In addition to the exposure information that is common to all of the instrument screens (page 152), you can use this screen to find:

- Which optical relay was used (F48 or F96)
- The image format (NORMAL or ZOOM)
- The field of view (pixels per line vs. lines per frame)
- The orientation of north on the frame
- The offset (i.e., starting position) of the sub-image (pixel number and line number)
- Which filter in each of the four filter wheels was in the beam
- The shutter mode (INBEAM or NOTUSED)
- The LED calibration lamp status (ACTIVE or NOTUSED)
- The status of the spectrographic mirror mechanism (INBEAM or NOTUSED)
- The status of the coronographic apodizer mask (INBEAM or NOTUSED)
- The RMS bandwidth of the filter/detector combination (in angstroms)

As described on page 152, you can use this screen to find all FOC observations that were made using instrument parameters equal (or similar) to those of a particular observation that you are interested in. Enter the appropriate search constraints in the relevant instrument-specific fields on this search screen to initiate such a catalog search.

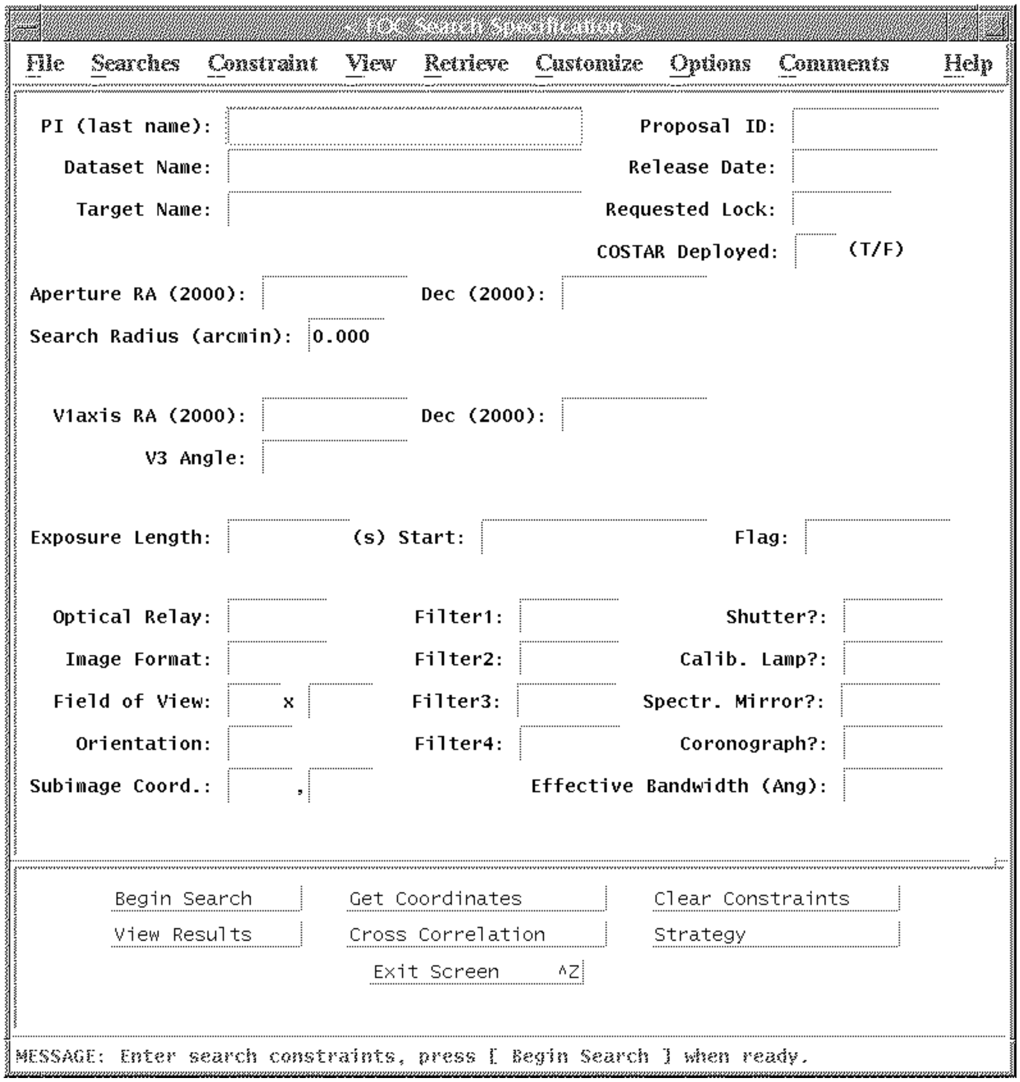

Figure 8.14: <FOC> Screen

<FOS> Screen

You can use this screen to search the HST catalog for detailed instrument-specific exposure information related to Faint Object Spectrograph (FOS) observations. In addition to the exposure information that is common to all of the instrument screens (page 152), you can use this screen to find:

- Which FOS detector was used (AMBER or BLUE)
- The ground software mode of the instrument (LED-FLAT-FIELD-MAP, TIME-RESOLVED, TIME-TAGGED, RAPID-READOUT, TARGET ACQUISITION, SPECTROSCOPY, or SPECTROPOLARIMETRY)
- The entrance aperture (using the codes designated [in parenthesis] in the first column of Table 29.3 of the *HST Data Handbook. Vol. II*)
- The position angle of the aperture (measured from north, along the +Y axis of the FOS field-of-view)
- The polarizer ID (A, B, C (= clear), or E (= error))
- The grating/disperser ID (using the codes designated [in parenthesis] in the first column of Table 29.4 of the *HST Data Handbook, Vol. II*)
- The minimum and maximum wavelengths of the observation (if specified by the proposer)
- The initial position angle of the polarizer
- The number of channels (i.e., diodes) read out
- The number of diodes that were over-scanned
- The number of steps (i.e., samples) taken per diode-width in a step pattern
- The acquisition mode

As described on page 152, you can use this screen to find all FOS observations that were made using instrument parameters equal (or similar) to those of a particular observation that you are interested in. Enter the appropriate search constraints in the relevant instrument-specific fields on this search screen to initiate such a catalog search.

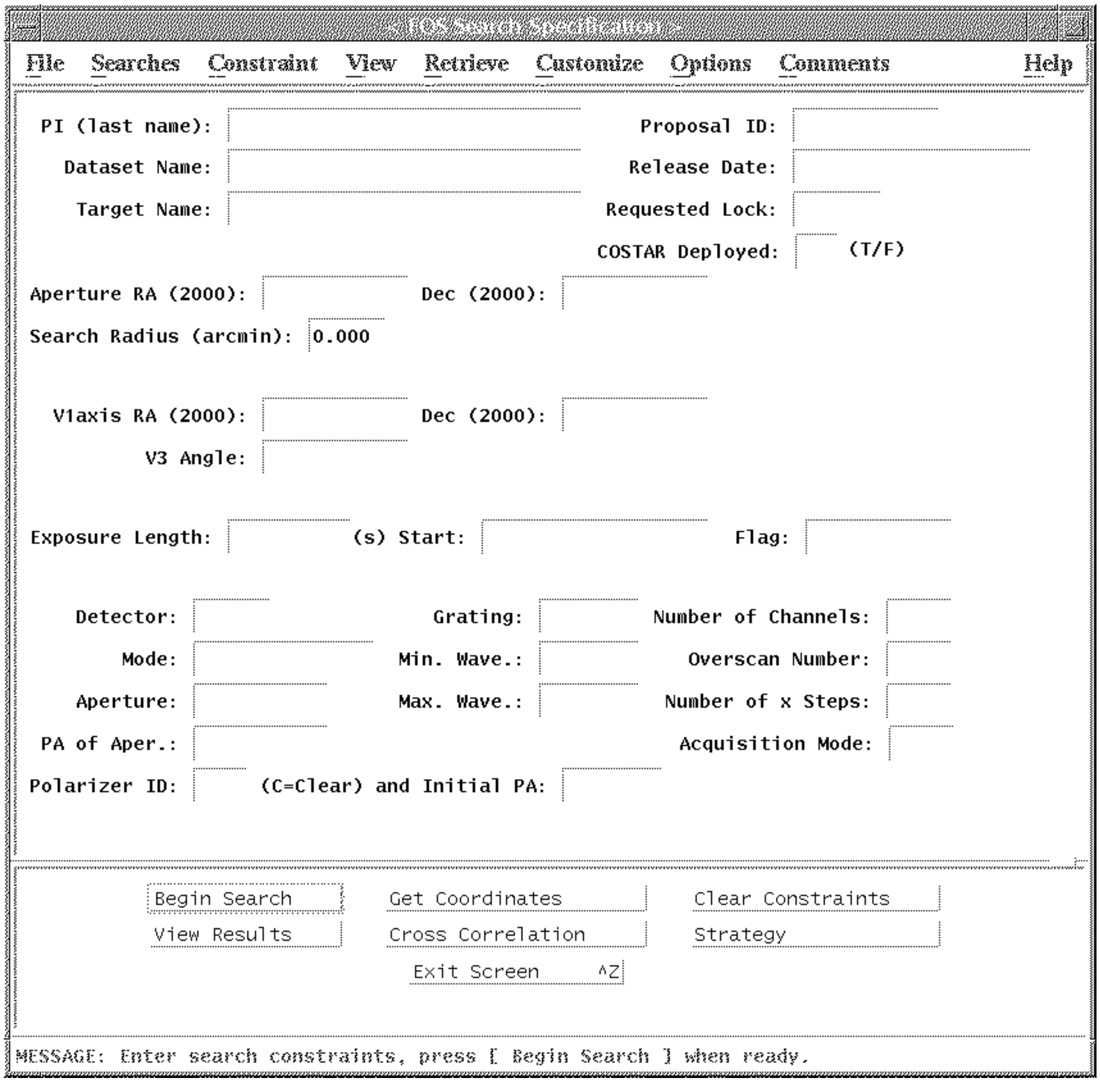

Figure 8.15: <FOS> Screen

<GHRS> Screen

You can use this screen to search the HST catalog for detailed instrument-specific exposure information related to observations using the Goddard High Resolution Spectrograph (GHRS). In addition to the exposure information that is common to all of the instrument screens (page 152), you can use this screen to find:

- Which GHRS detector was used (1 or 2)
- The observation mode
- The aperture used for the observation (SSA (= 0.25 arcsec), LSA (= 2.0 arcsec), or SC2 (for WAVE calibrations))
- The position angle of the target
- The spectral order of the echelle
- The grating used
- The minimum and maximum wavelengths of the observation
- The total flux from the target in the eight acquisition diodes obtained during the last frame of the target acquisition observation
- The step pattern of photocathode image deflections (1, 2, ..., 15; as described in the *HST Data Handbook*, *Vol. II*)
- The integration time at each position in the step pattern
- The fixed-pattern, spectrum-splitting keyword (FPSPLIT = NO, STD, TWO, FOUR, DSTWO, or DSFOUR)
- The expected number of observation repeats
- The recombined spectrum keyword (COMB-ADDITION = NO, TWO, FOUR, DSTWO, or DSFOUR)

As described on page 152, you can use this screen to find all GHRS observations that were made using instrument parameters equal (or similar) to those of a particular observation that you are interested in. Enter the appropriate search constraints in the relevant instrument-specific fields on this search screen to initiate such a catalog search.

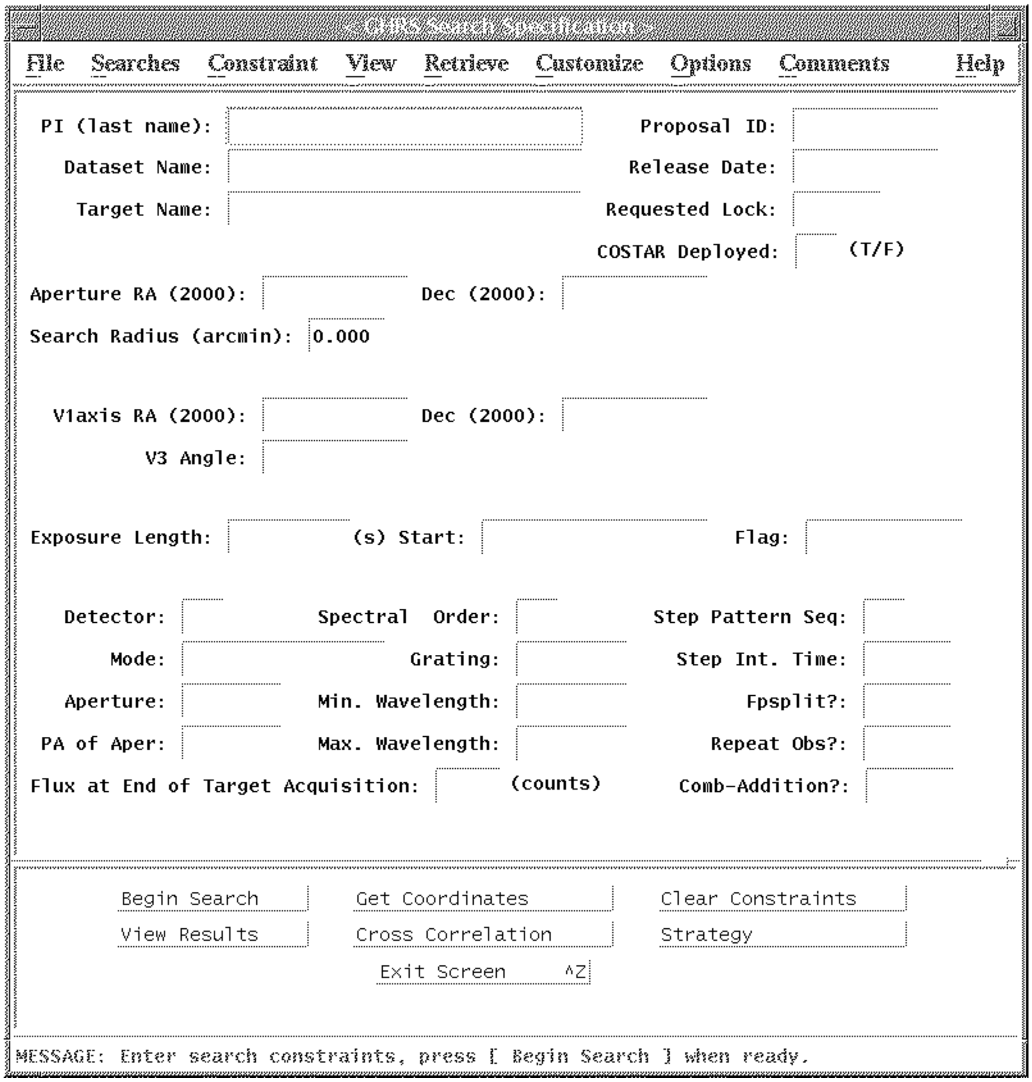

Figure 8.16: <GHRS> Screen

<HSP> Screen

You can use this screen to search the HST catalog for detailed instrument-specific exposure information related to High Speed Photometer (HSP) observations. In addition to the exposure information that is common to all of the instrument screens (page 152), you can use this screen to find the:

- Instrument mode (SCP (single-color photometry), SSP (star/sky photometry), ARS (area scan), or DUM (dump))
- Detector used (0 (= none), 1 (= POL), 2 (= UV1), 3 (= VIS), 4 (= UV2), or 5 (= PMT))
- Aperture used for the object
- Sample time (i.e., time of integration)
- X and Y components of the object position's offset in the aperture
- Data source (STAR, SKY, or AREA SCAN)
- Data type (DIGITAL or ANALOG)
- Data format (BYTE, WORD, LWRD, ALOG, or ALL)
- Longitude of the prime meridian (for planetary target)
- Epoch of the longitude of the prime meridian (for planetary target)

As described on page 152, you can use this screen to find all HSP observations that were made using instrument parameters equal (or similar) to those of a particular observation that you are interested in. Enter the appropriate search constraints in the relevant instrument-specific fields on this search screen to initiate such a catalog search.

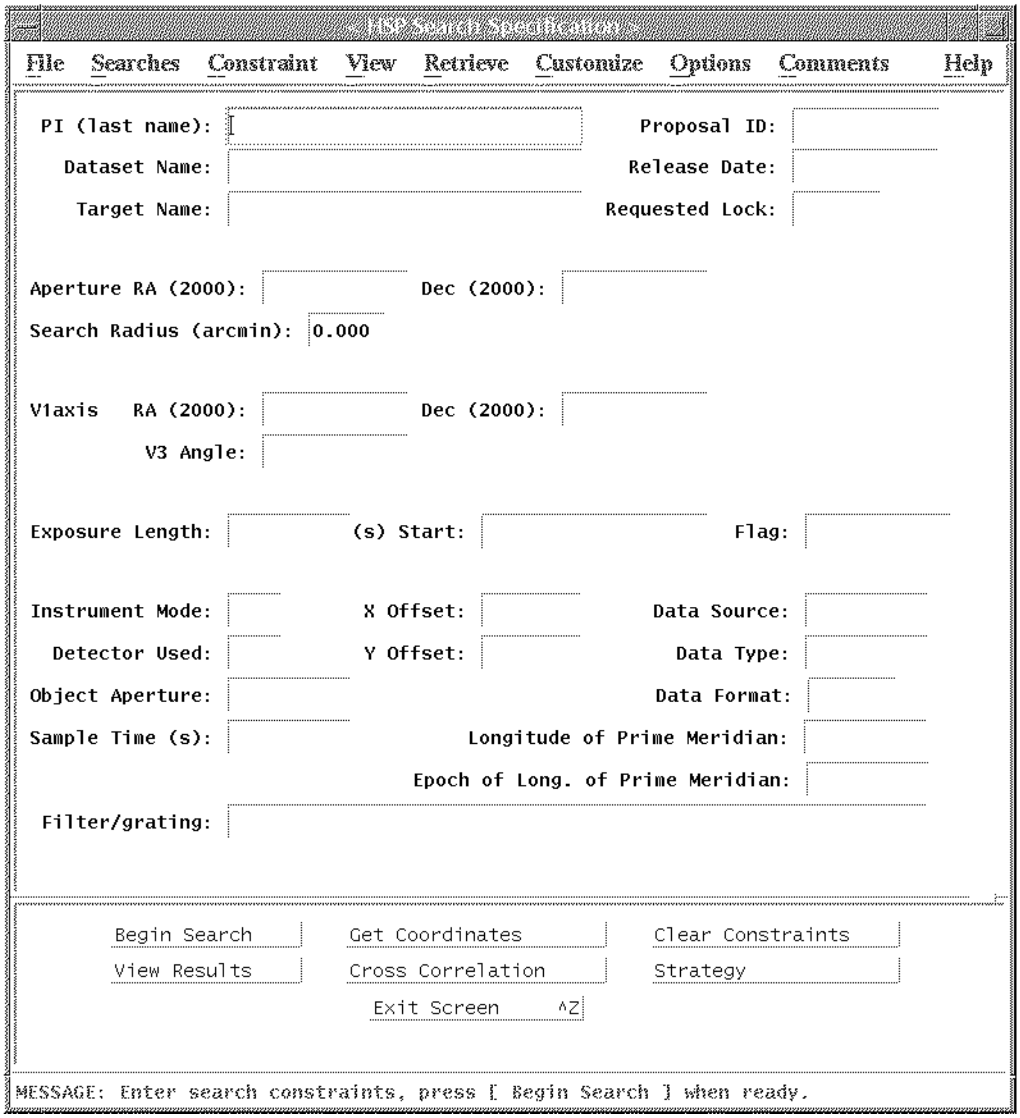

Figure 8.17: <HSP> Screen

<NICMOS> Screen

You can use this screen to search the HST catalog for detailed instrument-specific exposure information related to observations using the Near Infrared Camera and Multi-Object Spectrometer (NICMOS). In addition to the exposure information that is common to all of the instrument screens (page 152), you can use this screen to find:

- Which camera was used (camera 1, 2, or 3)
- Which aperture was used (NIC1, NIC1-FIX, NIC2, NIC2-FIX, NIC-CORON, NIC2-ACQ, NIC3, NIC3-FIX)
- The observation mode used (ACCUM, MULTI-ACCUM, BRIGHT OBJECT, ACQ RAMP)
- The image type (DARK, BIAS, INTFLAT, FLAT, EXTERNAL, EARTH-CALIB, or SPECIAL)
- The filters used (see the *NICMOS Instrument Handbook* for a complete summary)
- The sample sequence or a pre-defined set of sample times for MULTI-ACCUM mode
- The orientation of the NICMOS cameras (spacecraft orientations are rotated by 225 degrees from NICMOS coordinate system)
- NREAD or the number of multiple reads of the initial pixel values which are averaged to define the initial signal level (1-25)
- NSAMP or the number of ACCUM samplings
- READOUT or the NICMOS detector readout modes (ACCUM, MULTIACCUM, BRIGHTOBS, and ACQ).

As described on page 152, you can use this screen to find all NICMOS observations that were made using instrument parameters equal (or similar) to those of a particular observation that you are interested in. Enter the appropriate search constraints in the relevant instrument-specific fields on this search screen to initiate such a catalog search.

The use of the <NICMOS Association Search> screen is described on page 172.

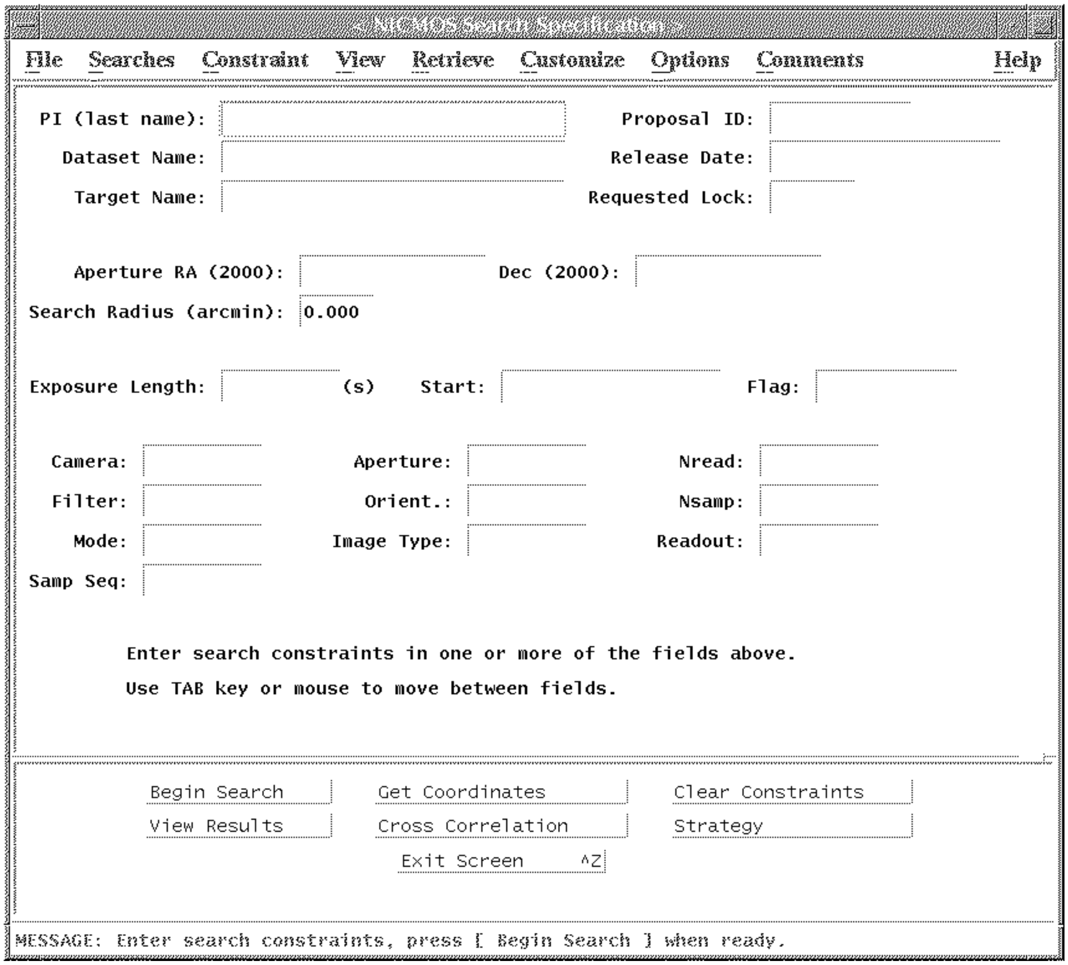

Figure 8.18: <NICMOS> Screen

<STIS> Screen

You can use this screen to search the HST catalog for detailed instrument-specific exposure information related to observations using the Space Telescope Imaging Spectrograph (STIS). In addition to the exposure information that is common to all of the instrument screens (page 152), you can use this screen to find:

- Which detector was used (STIS/CCD, MAMA, STIS/FUV-MAMA)
- The observation mode used (ACCUM and TIME-TAG)
- The optical elements in use (grating and filter)
- The central wavelength
- The aperture used (a complete summary of available apertures is presented in the *STIS Instrument Handbook)*
- Which calibration lamp subsystem was used (HITM, IM, NONE)
- Which was the primary instrument in case an observation was taken in parallel
- If a subarray (T) or if the full array (F) was used by the detector
- In the case of a CCD subarray the dispersion (which runs along AXIS1) and the long axis of the slit (which runs along AXIS2)
- The configuration status
- Whether the global linearity level was exceeded
- Number of cosmic ray split exposures (CRSPLITS)
- Number of repeat exposures in set (default = 1)
- Whether the Local Rate Check image (LRC) exists (T/F)
- If the Local Rate Check (LRC) failed (T/F).

As described on page 152, you can use this screen to find all STIS observations that were made using instrument parameters equal (or similar) to those of a particular observation that you are interested in. Enter the appropriate search constraints in the relevant instrument-specific fields on this search screen to initiate such a catalog search.

The use of the <STIS Association Search> screen is described on page 174.

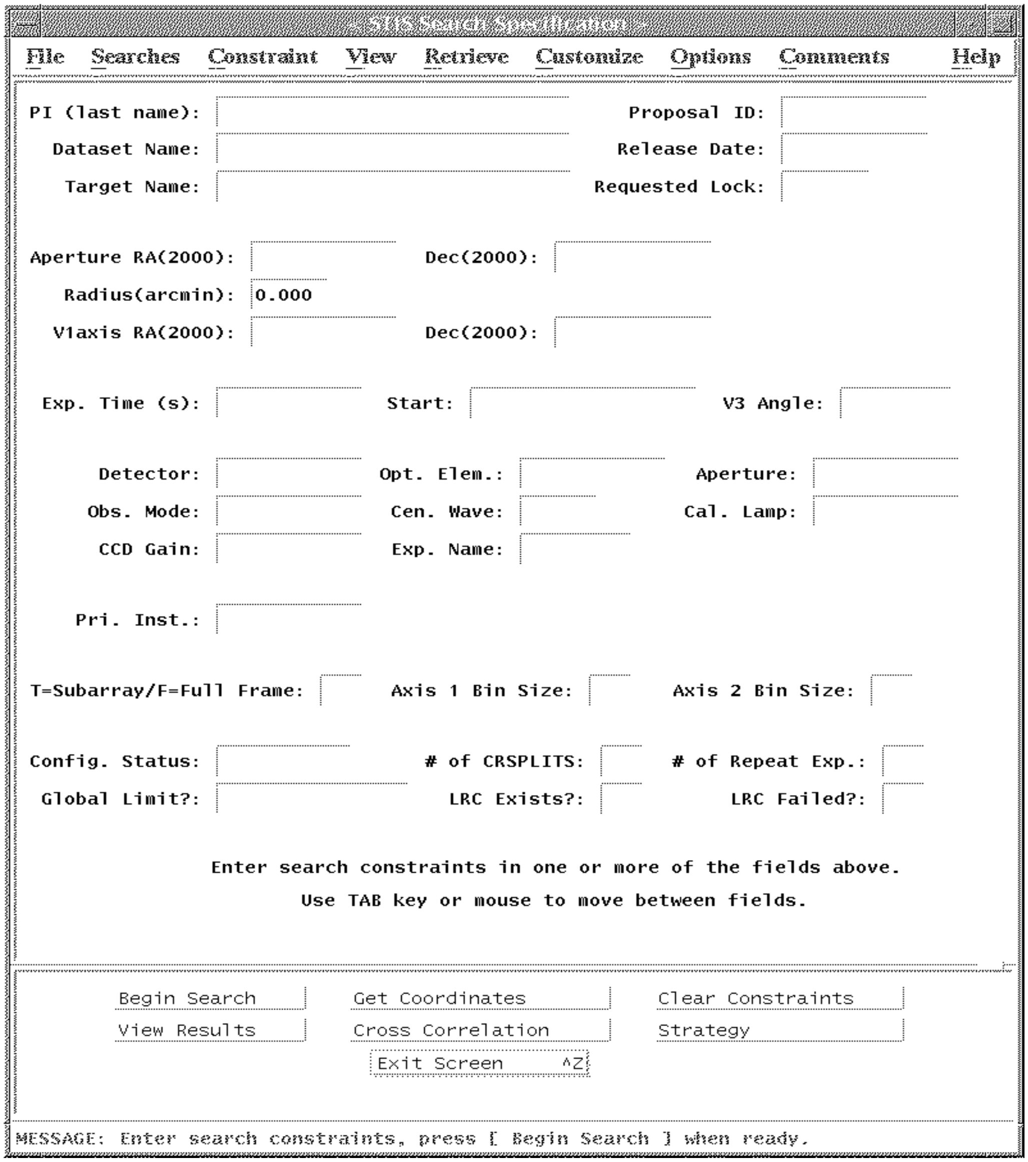

Figure 8.19: <STIS> Screen

<WFPC> Screen

You can use this screen to search the HST catalog for detailed instrument-specific exposure information related to observations using the Wide Field Planetary Camera (WFPC). In addition to the exposure information that is common to all of the instrument screens (page 152), you can use this screen to find:

- Which camera was used (WF (wide field) or PC (planetary camera))
- The observation mode used (FULL (full resolution, 800 x 800) or AREA (area integration, 400 x 400))
- The image type (DARK, BIAS, INTFLAT, PREF, FLAT, KSPOTS, EXTERNAL, EARTH-CALIB, or SPECIAL)
- The filters used
- The predicted preflash time
- The target acquisition mode (00 (null), 01 (ground assisted), 02 (onboard computer assisted), or 03 (fixed simple pointing))
- The orientation of the four CCD chips

As described on page 152, you can use this screen to find all WF/PC observations that were made using instrument parameters equal (or similar) to those of a particular observation that you are interested in. Enter the appropriate search constraints in the relevant instrument-specific fields on this search screen to initiate such a catalog search.

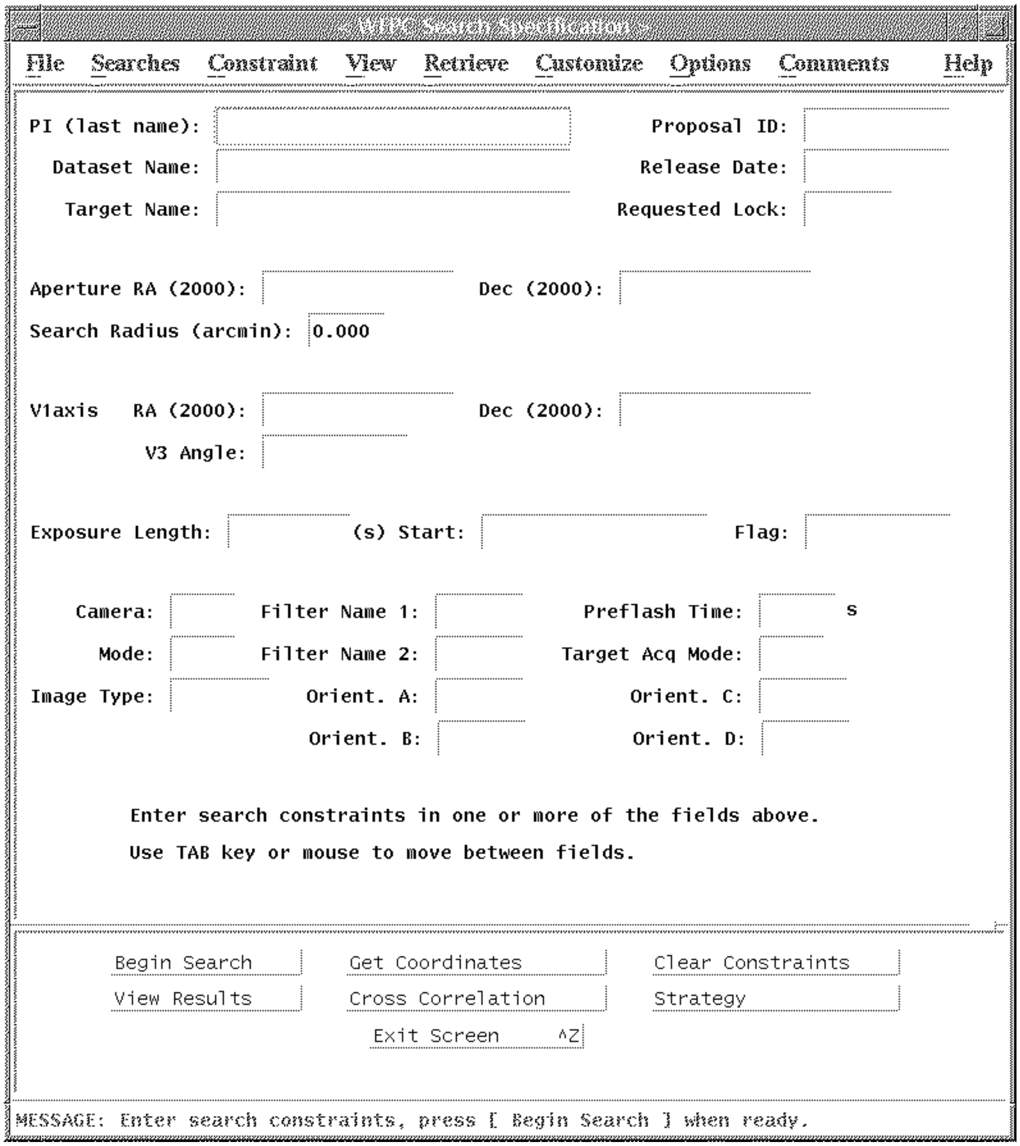

Figure 8.20: <WFPC> Screen

<WFPC-2> Screen

You can use this screen to search the HST catalog for detailed instrument-specific exposure information related to WFPC-2 observations. In addition to the exposure information that is common to all of the instrument screens (page 152), you can use this screen to find:

- The observation mode used (FULL (full resolution, 800 x 800) or AREA (area integration, 400 x 400))
- The image type (DARK, BIAS, INTFLAT, PREF, FLAT, KSPOTS, EXTERNAL, EARTH-CALIB, or SPECIAL)
- The filters used
- The target acquisition mode (00 (null), 01 (ground assisted), 02 (onboard computer assisted), or 03 (fixed simple pointing))
- The orientation of the four CCD chips

As described on page 152, you can use this screen to find all WFPC-2 observations that were made using instrument parameters equal (or similar) to those of a particular observation that you are interested in. Enter the appropriate search constraints in the relevant instrument-specific fields on this search screen to initiate such a catalog search.

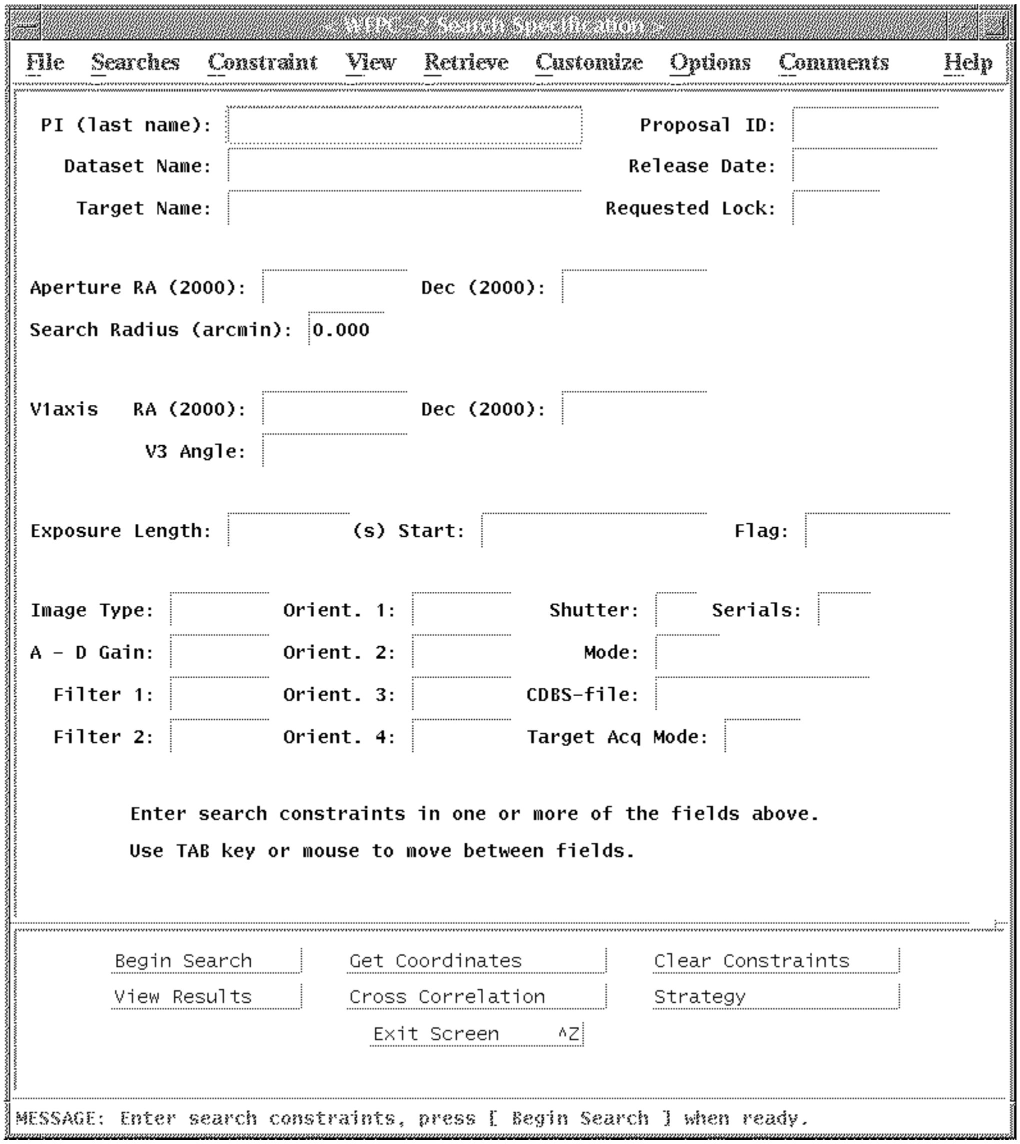

Figure 8.21: <WFPC-2> Screen

Association Screens

The STIS and NICMOS science instruments have posed new expectations and requirements on the processing and archiving of HST data. The association of exposures is in fact the central aspect of the data handling for NICMOS and STIS that permits the compact combination of multiple exposures to produce meta datasets or products.

The most fundamental element within the HST ground system is the “exposure.” First generation HST Science Instruments are commanded to generate single exposures, which result from a distinct sequence of commands to the instrument. The resulting data are then assembled into a single “dataset.” Each of these datasets is given a unique 9 character identifier (see page 214) and is pipeline processed, calibrated, and archived separately from all other datasets.

For STIS and NICMOS, the combination of data from two or more exposures is often necessary to create a scientifically useful data product. Associations simplify the use of HST data by identifying a set of exposures that belong together and depend upon one another. An association permits all these exposures to be calibrated, archived, retrieved, and reprocessed as a set rather than as individual observations.

When a user searches the Archive with StarView for observations involving associations of exposures using the “standard” screens (e.g., the <Quick Search> or <General Search> screens), the search will identify the final association product (the rootnames of association products always end in zero: see Table 9.1 on page 215). If one requests both Calibrated and Uncalibrated data from the Archive (see Figure 8.39 on page 195), one will receive both the association product and the exposures that went into making it. The corresponding association table, located in the file with suffix `_asn` and the same rootname as the association product, will list the exposures belonging to the association. The exposure IDs in the association table share the same `ipppss` sequence as the association rootname, followed by a base 36 number nn (n = 0-9, A-Z) that uniquely identifies each exposure, and a character `t` that denotes the data transmission mode (see Table 9.1).

The <Association> screens are the only means to search the Archive for detailed information about the association status of NICMOS and STIS observations. The NICMOS association screen provides the only means for retrieving individual exposures from within an association. These screens are described below.

<NICMOS Association Search> Screen

The <NICMOS Association Search> screen represents the only way to search the Archive for detailed information about the association status of NICMOS observations. The results of the search request are returned on the <NICMOS Association Results> screen. In addition to the exposure information that is common to all of the instrument screens (page 152), you can use this screen to search on, for example:

- Association ID (if a dataset is not a member of an association, this keyword will be set to NONE)
- Pattern, that is the set of images of the same astronomical target obtained at pointings offset (see the *NICMOS Instrument Handbook* for a list of pre-designed patterns)
- The number of positions used as pointing offsets to form a pattern, Numpos
- Offset, which defines which type of telescope motion will be performed during a pattern in order to dither or chop (see the *NICMOS Instrument Handbook* for a list of available options).

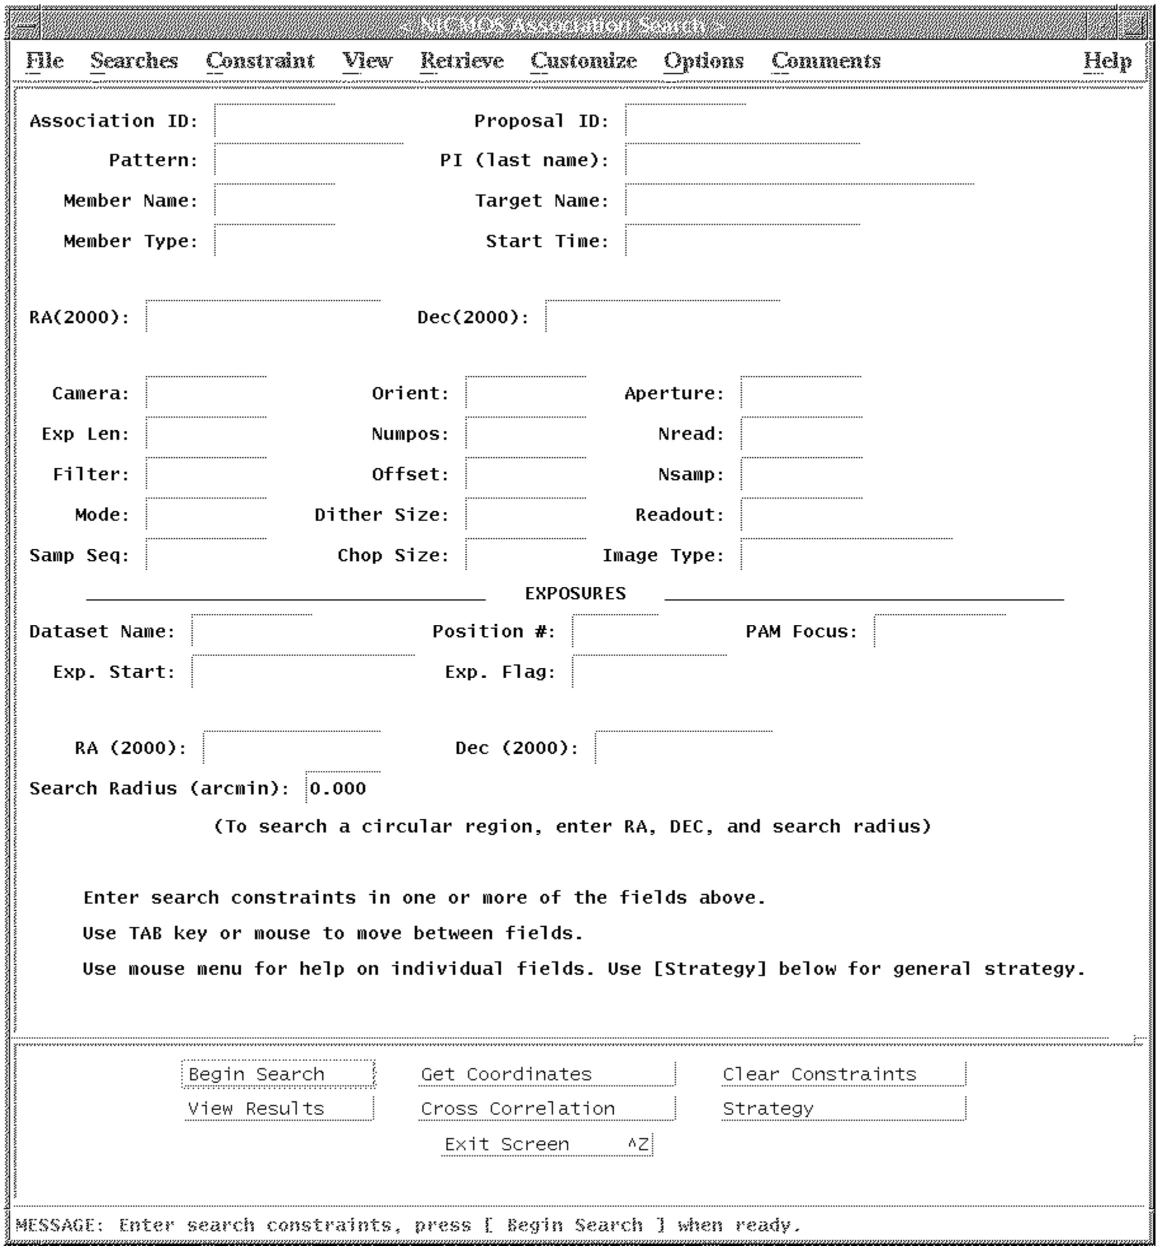

Figure 8.22: <NICMOS Association Search> Screen

<STIS Association Search> Screen

The <STIS Association Search> screen represents the only way to search the Archive for detailed information about the association status of STIS observations. The results of the search request are returned on the <STIS Association Results> screen. In addition to the exposure information that is common to all of the instrument screens (page 152), you can use this screen to search on, for example:

- Association ID (if a dataset is not a member of an association, this keyword will be set to NONE)
- Association Status (COMPLETE if all of its exposures were received, INCOMPLETE otherwise)
- Generation Date
- Association Member Type. This refers to individual image extensions within the file (e.g. CRSPLIT, SINGSCI, RPTOBS, WAVE).

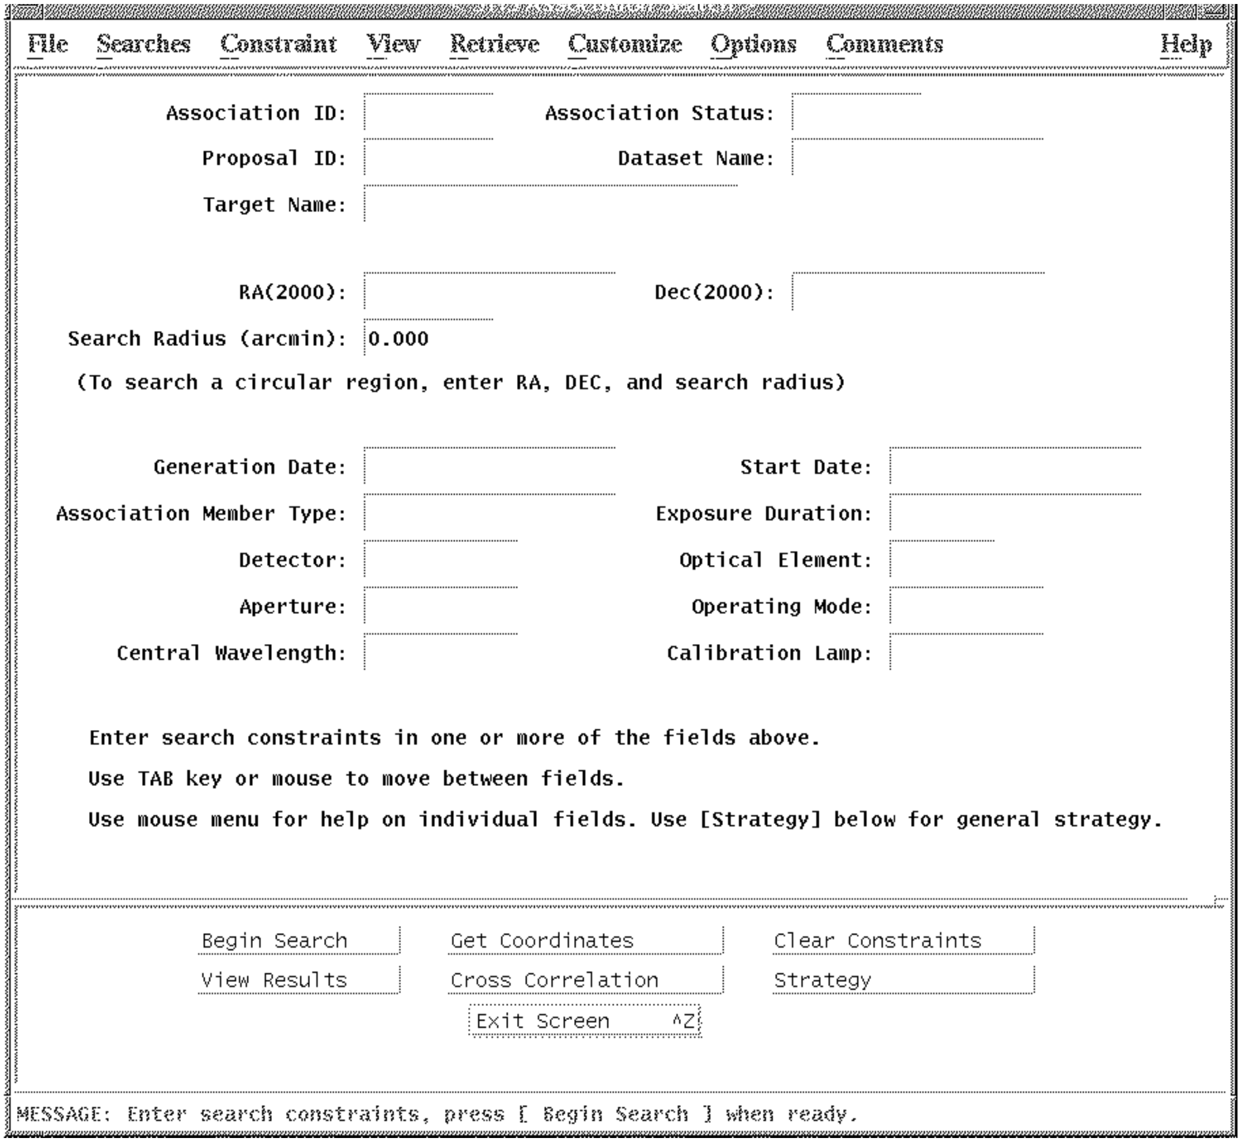

Figure 8.23: <STIS Association Search> Screen

Reference and Calibration Screens

StarView provides several screens that list the reference files that were used to calibrate each of the observations stored in the HST archive, all accessible from the <HST Instrument Searches> Screen. There is one screen per scientific instrument (except for the FGS). These screens also list the calibration reference files that are now determined to be the best files to use in recalibrating each observation. In most cases, the “used” calibration files are the same as the “recommended” files, indicating that it is not necessary to recalibrate those observations.

However, a dataset’s recommended calibration files may differ from those used if, in retrospect, it appears that a better file can now be used. This happens occasionally. However, finding that a file or table has changed doesn’t always mean that you’ll have to recalibrate. That depends very much on which file or table changed, and whether that kind of correction is likely to affect your analysis. This is not always easy to determine. You can find additional information on the significance of the reference files to the calibration process in the *HST Data Handbook*.

Finally, the <HST Instrument Searches> screen provides also access to a set of “Calibration” screens. These are instrument-specific and normally used only by Instrument Scientists.

<FOC Reference Files> Screen

You can use this screen to search the HST catalog for detailed instrument-specific information concerning the reference files used in calibrating HST observations using the FOC. The different types of information that are available on this screen are: general dataset parameters; instrument-specific exposure parameters; the names of the USED and RECOMMENDED calibration files; the corresponding LEVEL OF CHANGE; and PERFORMED values, indicating whether that calibration step was omitted or completed.

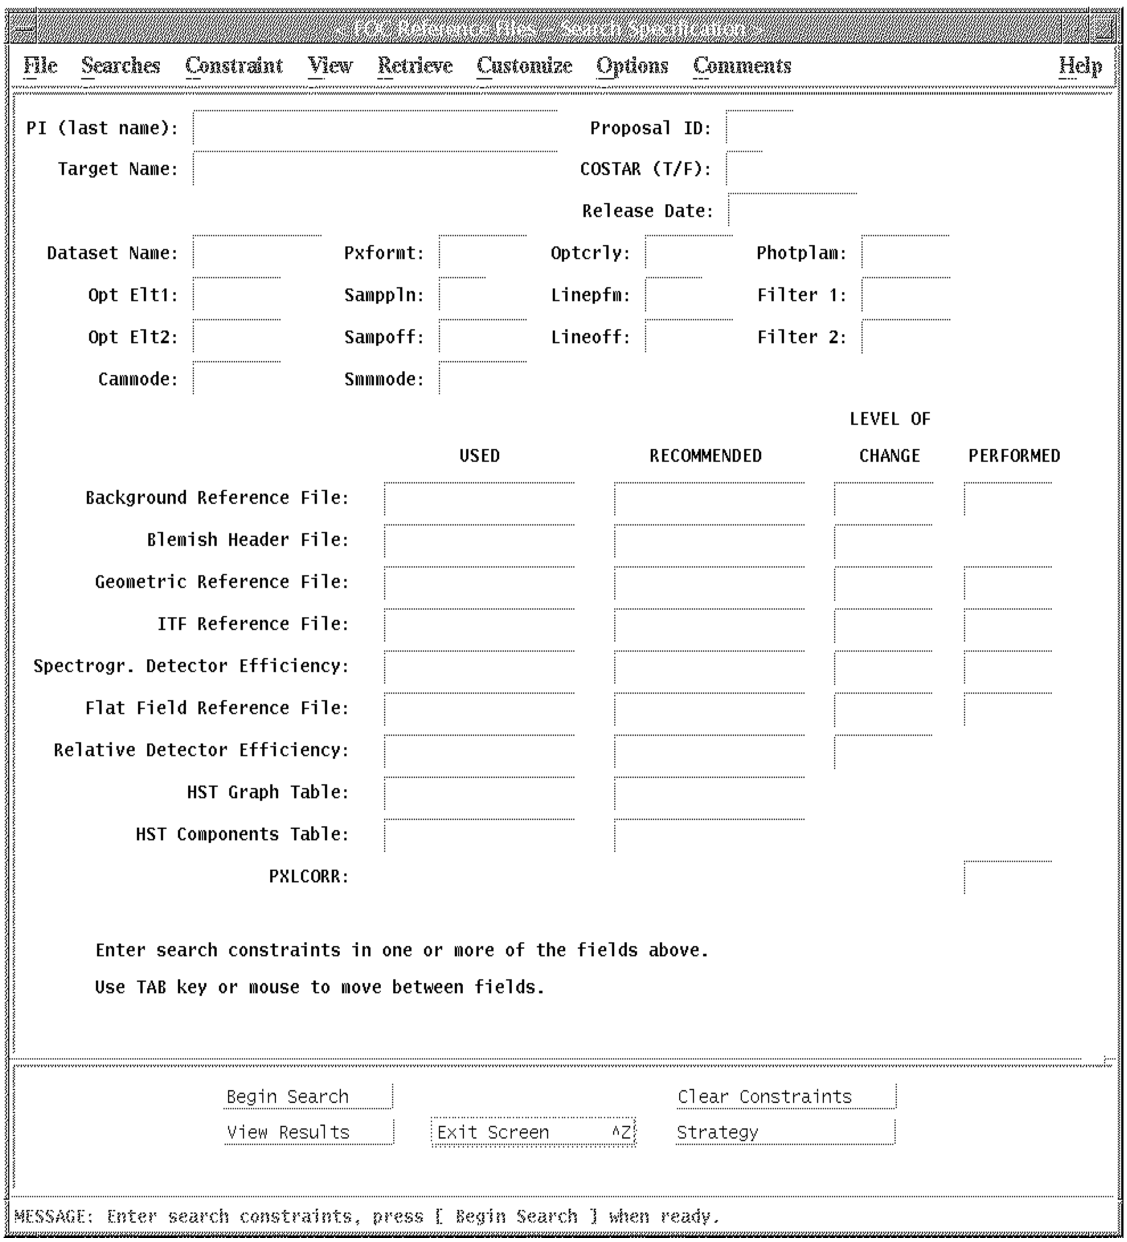

Figure 8.24: <FOC Reference Files> Screen

<FOS Reference Files> Screen

You can use this screen to search the HST catalog for detailed instrument-specific information concerning the reference files used in calibrating HST observations using the FOS. The different types of information that are available on this screen are: general dataset parameters; instrument-specific exposure parameters; the names of the USED and RECOMMENDED calibration files; the corresponding LEVEL OF CHANGE; and PERFORMED values, indicating whether that calibration step was omitted or completed.

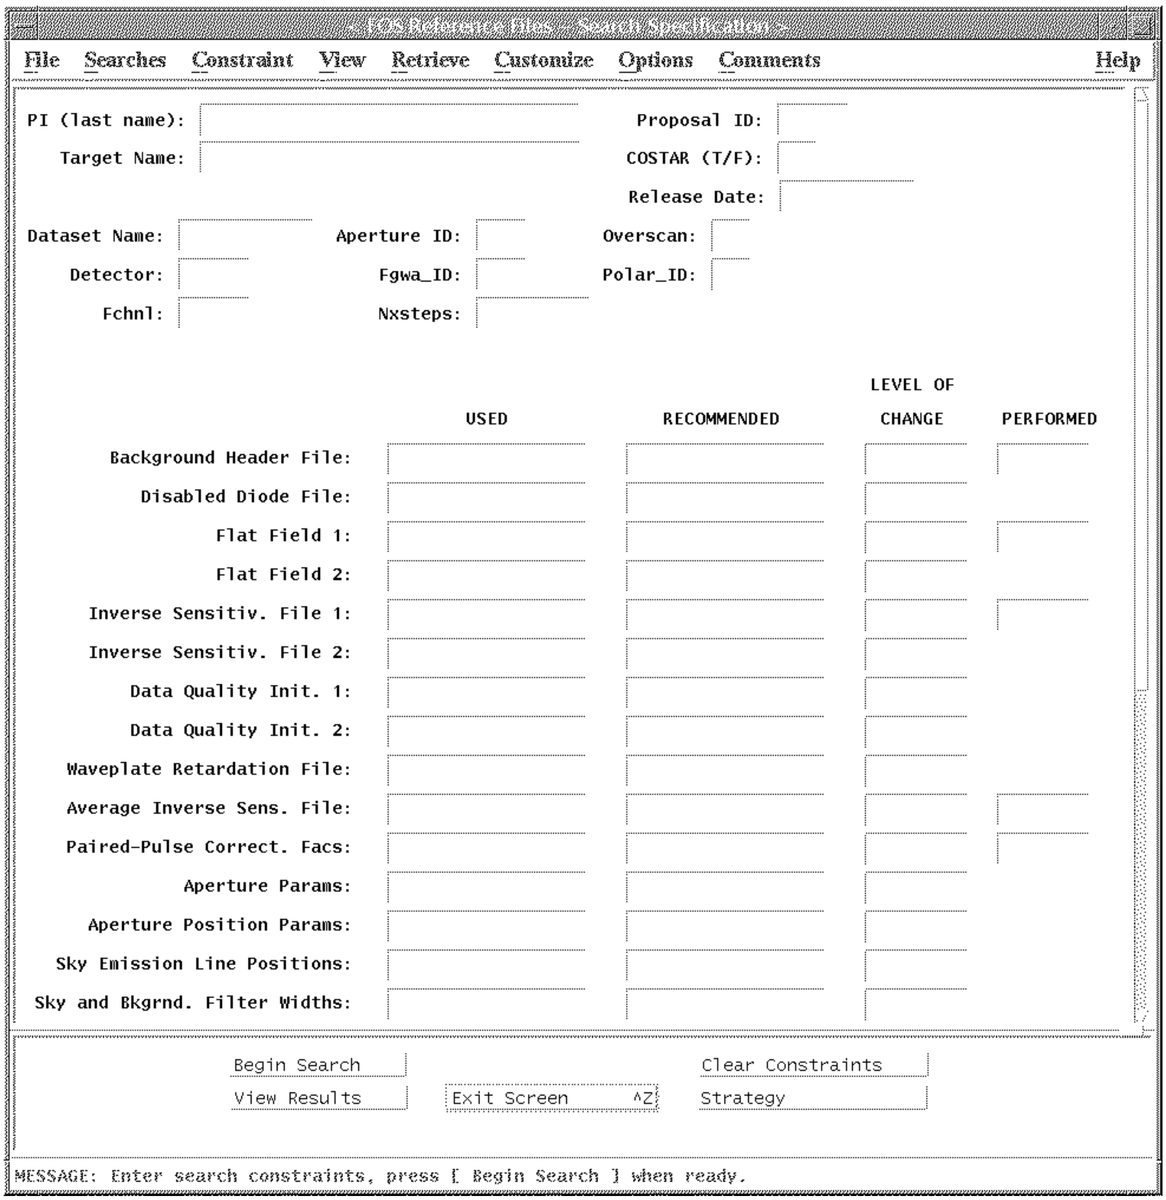

Figure 8.25: <FOS Reference Files> Screen

<GHRS Reference Files> Screen

You can use this screen to search the HST catalog for detailed instrument-specific information concerning the reference files used in calibrating HST observations using the GHRS. The different types of information that are available on this screen are: general dataset parameters; instrument-specific exposure parameters; the names of the USED and RECOMMENDED calibration files; the corresponding LEVEL OF CHANGE; and PERFORMED values, indicating whether that calibration step was omitted or completed.

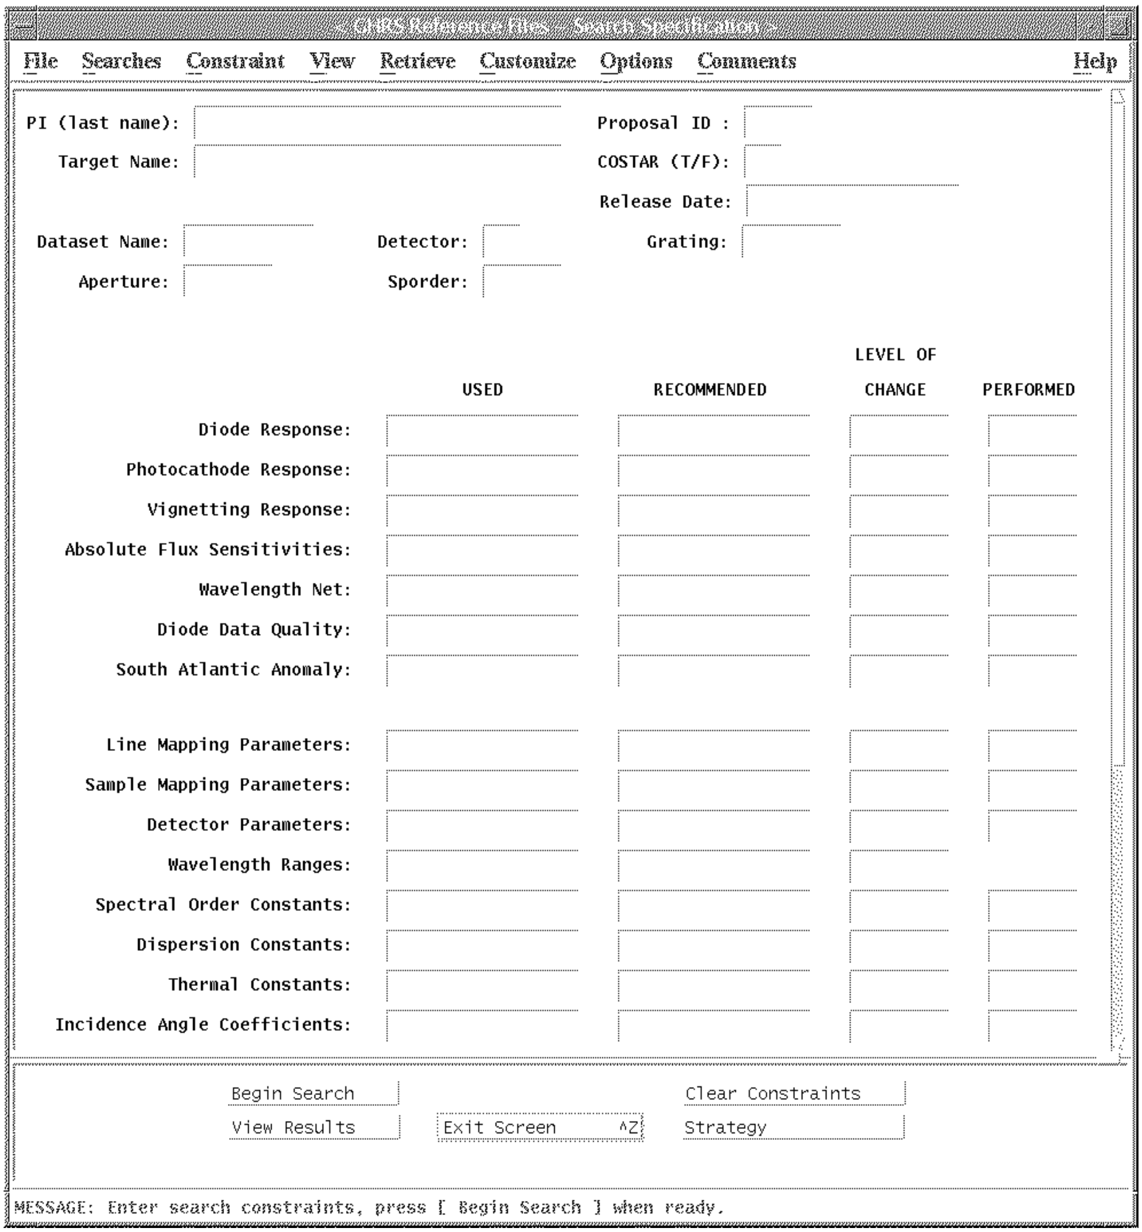

Figure 8.26: <GHRS Reference Files> Screen

<HSP Reference Files> Screen

You can use this screen to search the HST catalog for detailed instrument-specific information concerning the reference files used in calibrating HST observations using the HSP. The different types of information that are available on this screen are general dataset parameters and the names of the USED and RECOMMENDED calibration files and the corresponding LEVEL OF CHANGE.

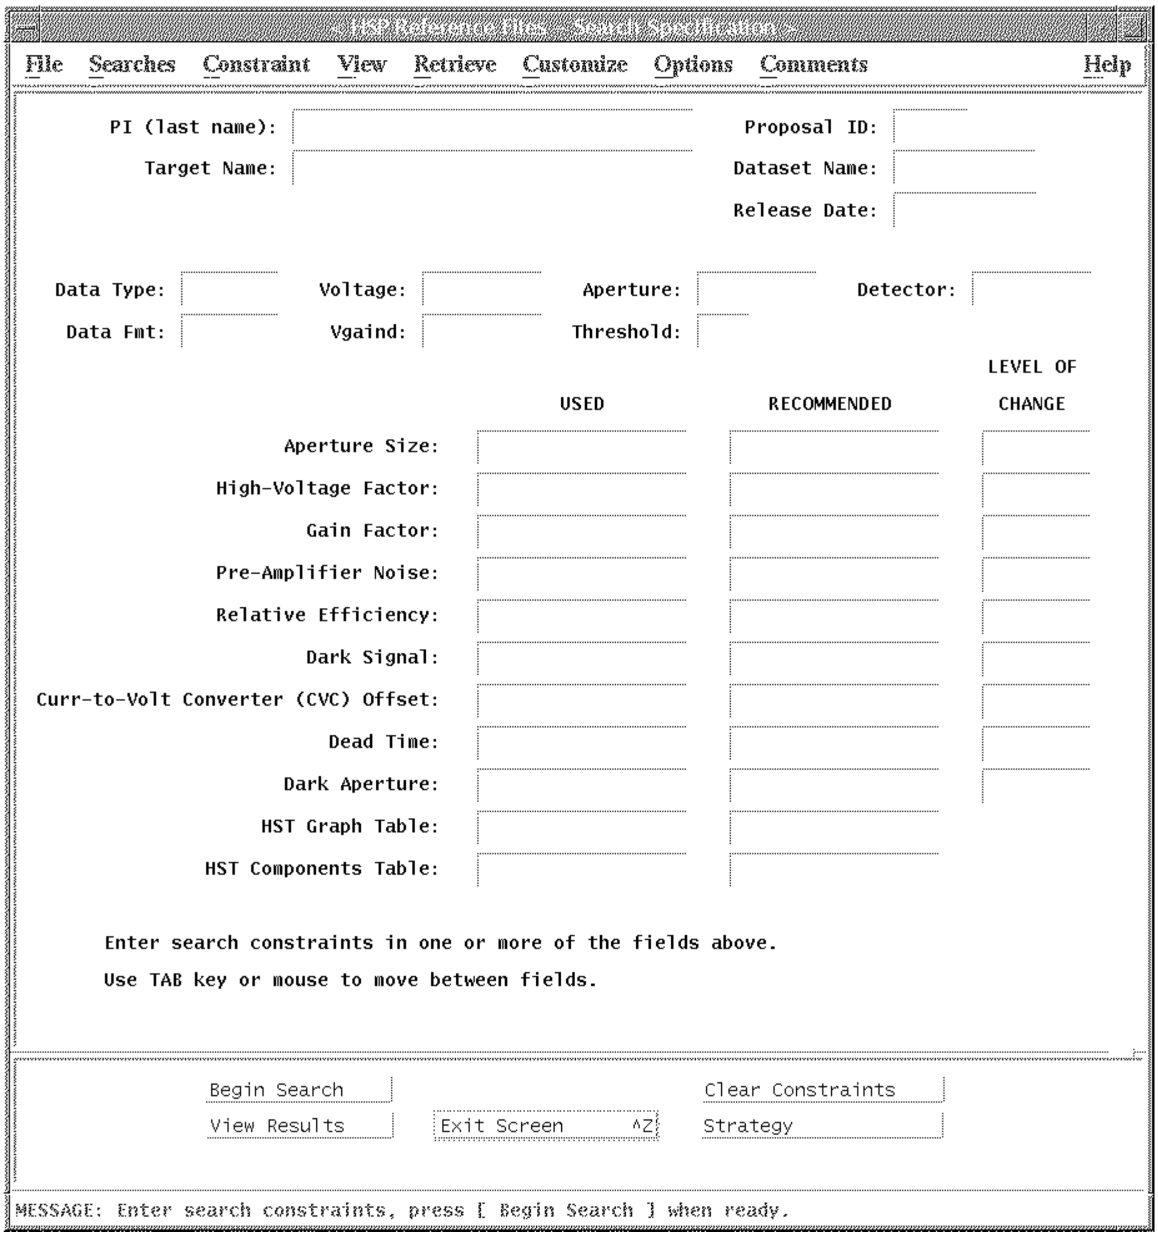

Figure 8.27: <HSP Reference Files> Screen

<NICMOS Reference Files> Screen

You can use this screen to search the HST catalog for detailed instrument-specific information concerning the reference files used in calibrating HST observations using NICMOS. The different types of information that are available on this screen are: general dataset parameters; instrument-specific exposure parameters; the names of the USED and RECOMMENDED calibration files; the corresponding LEVEL OF CHANGE; and PERFORMED values, indicating whether that calibration step was completed or not.

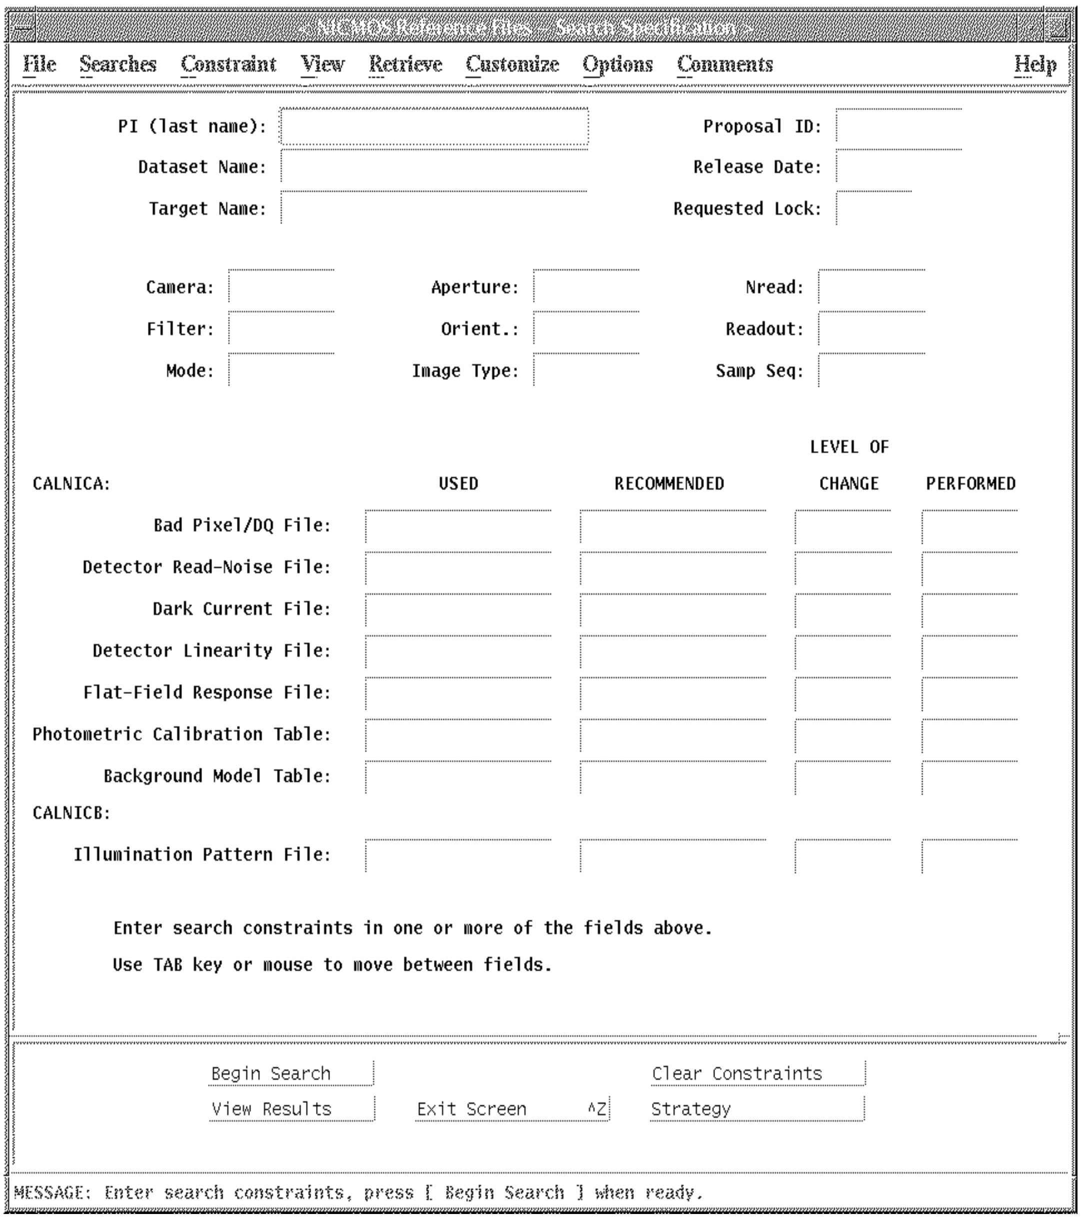

Figure 8.28: <NICMOS Reference Files> Screen

<STIS Reference Files> Screen

You can use this screen to search the HST catalog for detailed instrument-specific information concerning the reference files used in calibrating HST observations using STIS. The different types of information that are available on this screen are: general dataset parameters; instrument-specific exposure parameters; the names of the USED and RECOMMENDED calibration files; and the corresponding LEVEL OF CHANGE.

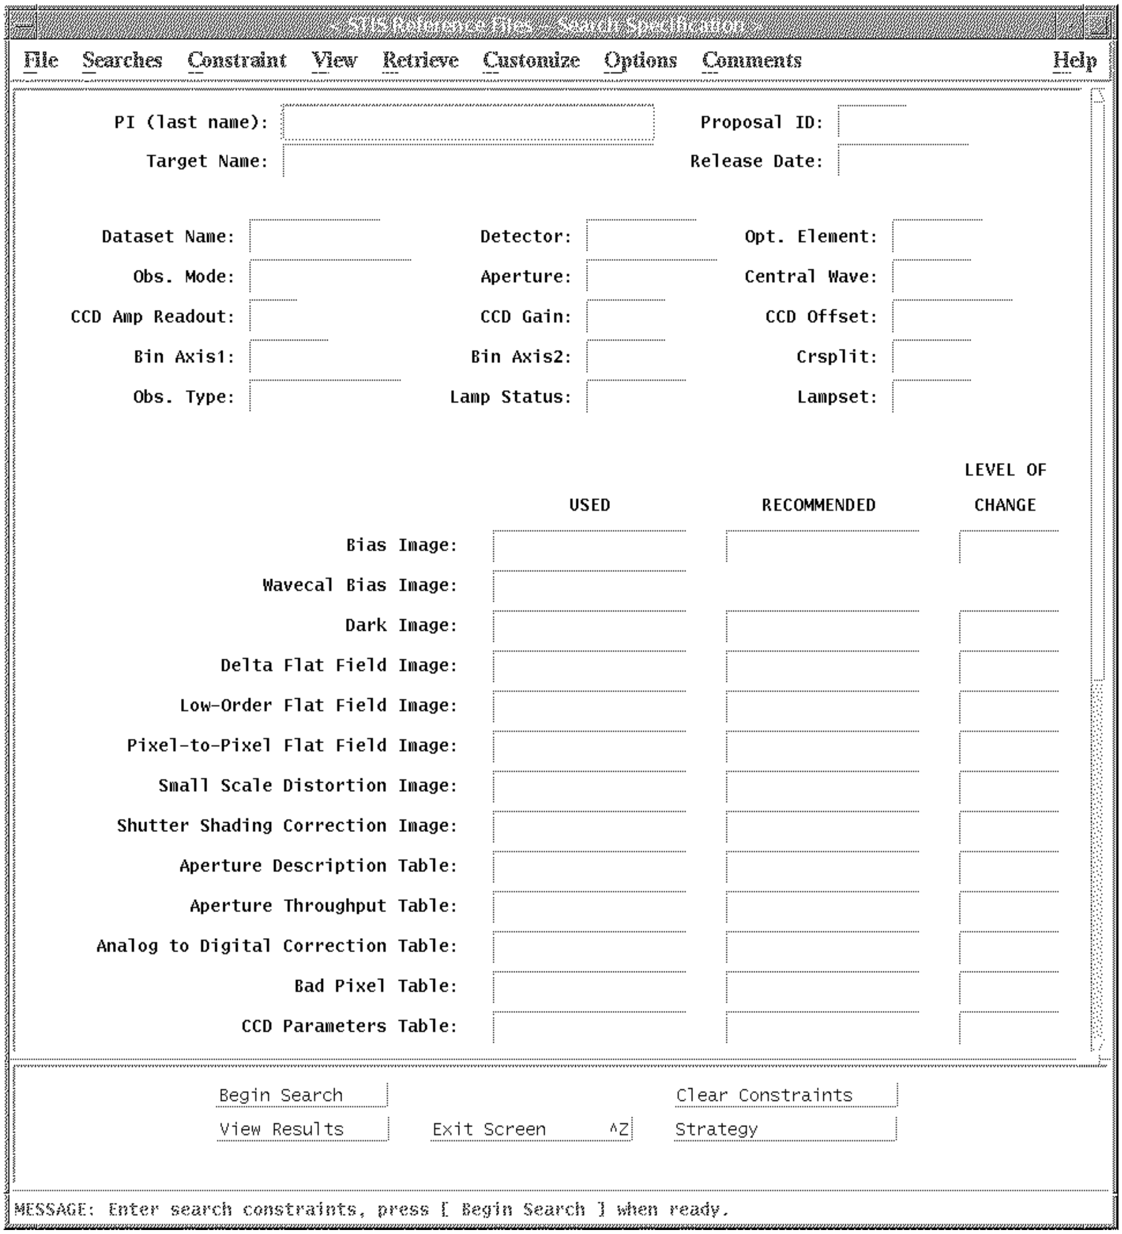

Figure 8.29: <STIS Reference Files> Screen

<WFPC Reference Files> Screen

You can use this screen to search the HST catalog for detailed instrument-specific information concerning the reference files used in calibrating HST observations using the WF/PC. The different types of information that are available on this screen are: general dataset parameters; instrument-specific exposure parameters; the names of the USED and RECOMMENDED calibration files; the corresponding LEVEL OF CHANGE; and PERFORMED values, indicating whether that calibration step was completed or not.

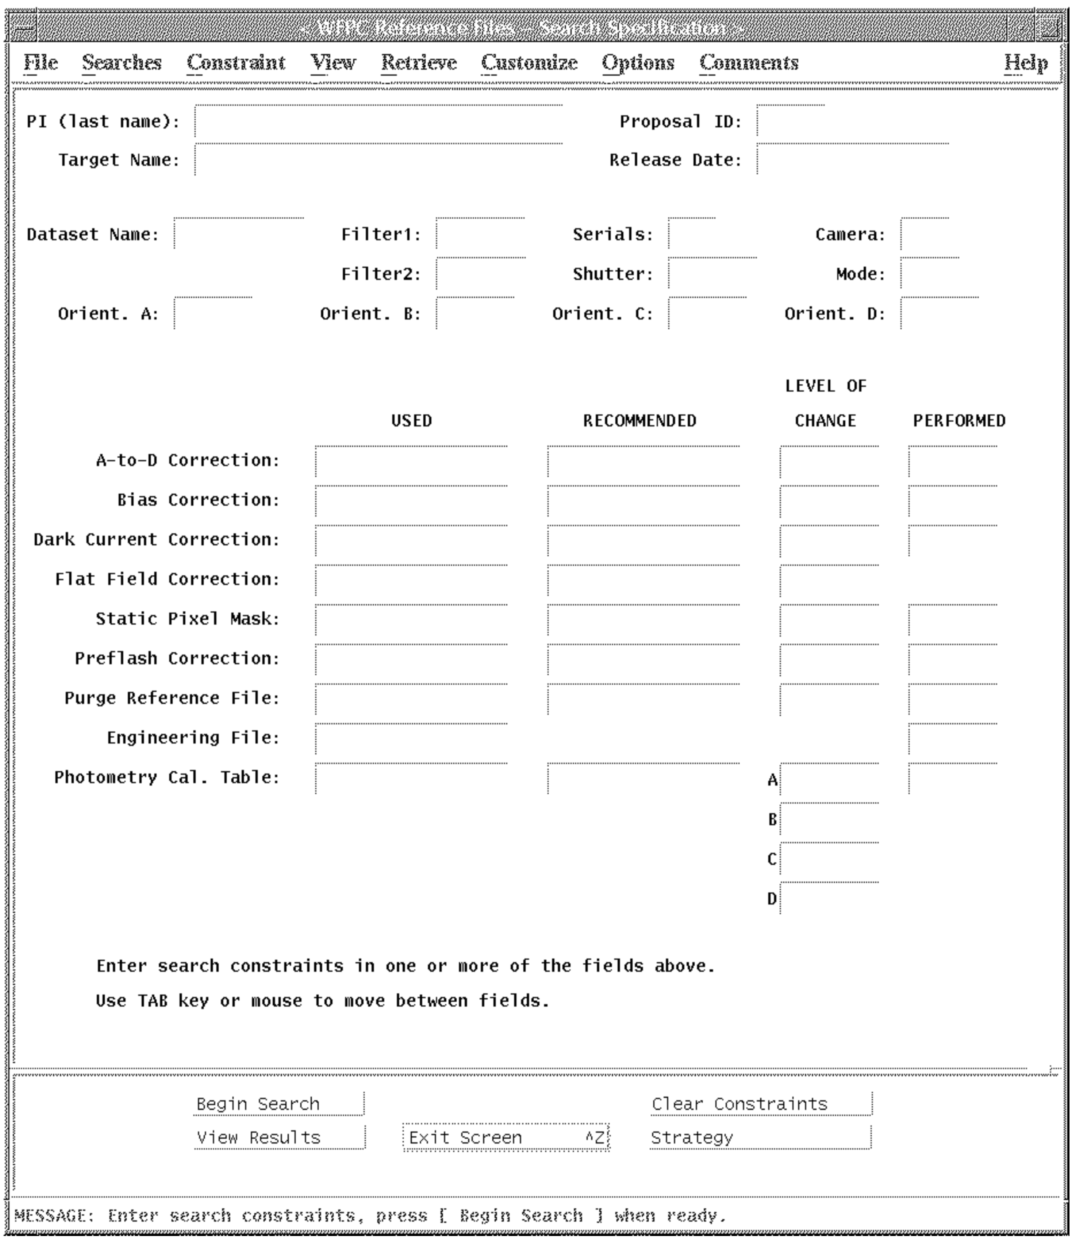

Figure 8.30: <WFPC Reference Files> Screen

<WFPC-2 Reference Files> Screen

You can use this screen to search the HST catalog for detailed instrument-specific information concerning the reference files used in calibrating HST observations using the WFPC-2. The different types of information that are available on this screen are: general dataset parameters; instrument-specific exposure parameters; the names of the USED and RECOMMENDED calibration files; the corresponding LEVEL OF CHANGE; and PERFORMED values, indicating whether that calibration step was completed or not.

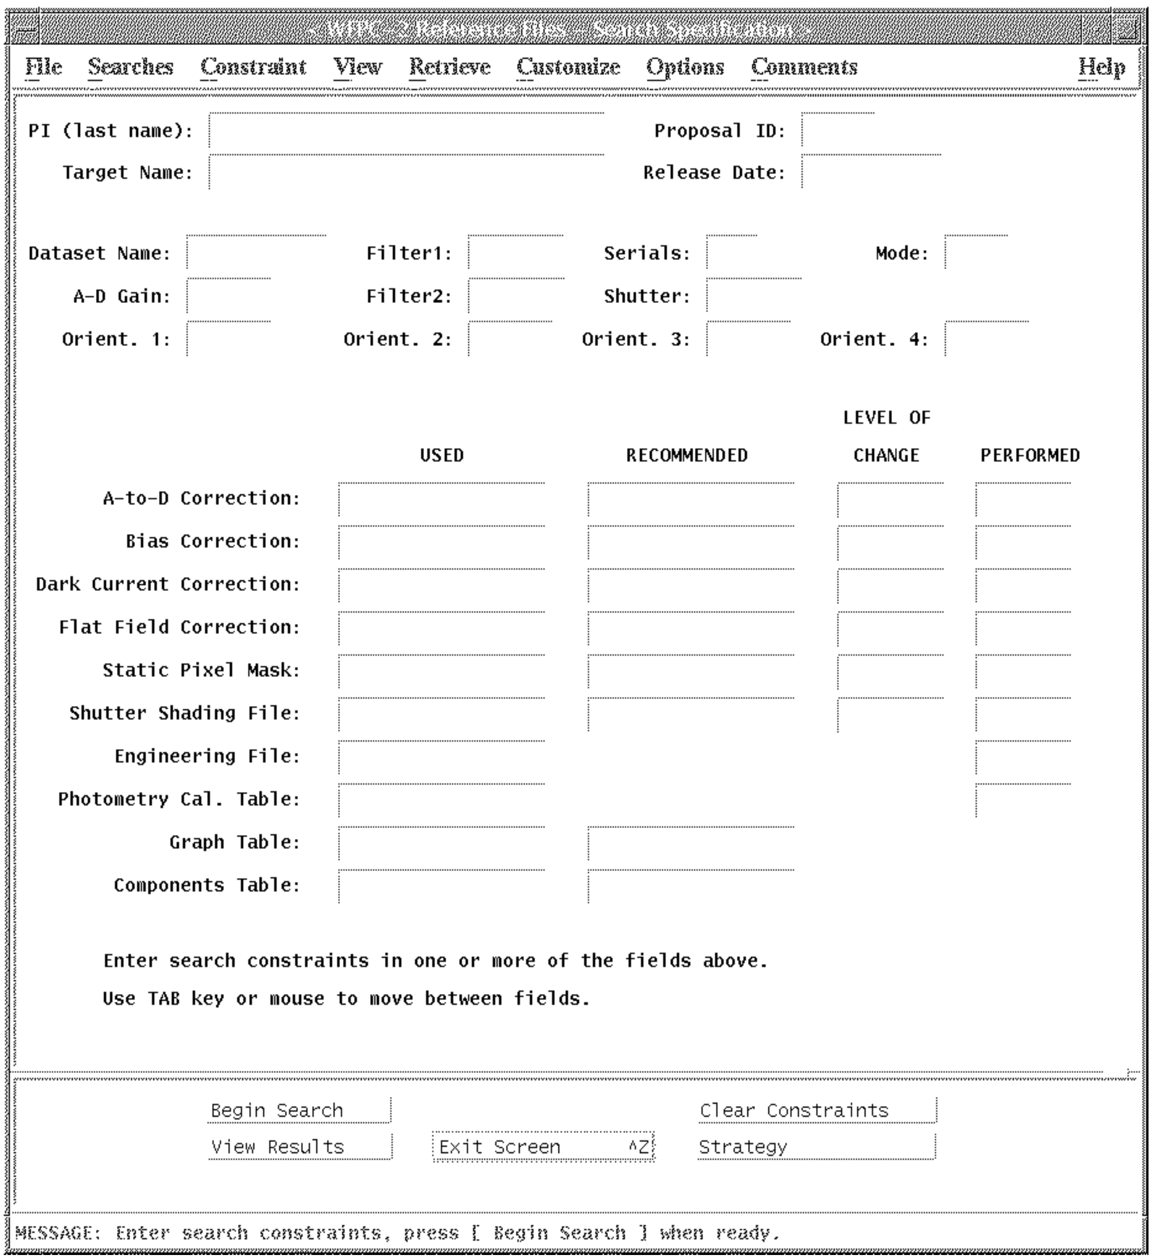

Figure 8.31: <WFPC-2 Reference Files> Screen

On-The-Fly Calibration Screens

The On-The-Fly Calibration (OTFC) service, described on page 135, will provide archival researchers with the ‘‘best’’ calibrated data without requiring them to go through the complex recalibration process themselves. Currently only WFPC-2 and STIS data will be processed in the OTFC pipeline. Eventually OTFC will be applied to NICOMS and future instruments data.

OTFC requests can be made through a modified version of the <Retrieval Request - File Options> screen or via the archive WWW interface, once OTFC is released externally (Fall 1999). Also, dedicated StarView screens for each instrument can be used to extract more information about the recalibration. These screens are also useful for the user interested in following all the steps of the recalibration and in matching each step with its corresponding calibration file. The Instrument OTFC screens can be accessed from the <HST Instrument Searches> screen. We note that the <Retrieval Request - File Options> screen should fulfill the needs of most users.

These OTFC screens are described below.

<Retrieval Request - File Options> Screen

The <Retrieval Request - File Options> screen is a modified version of the retrieval screen described on page 195. The only difference is an **[OTFC]** button used to request that the retrieval process goes through the OTFC pipeline. This screen will be the default when OTFC is released externally to STScI (but the **[OTFC]** button will obviously only work for the relevant instruments, currently STIS and WFPC-2).

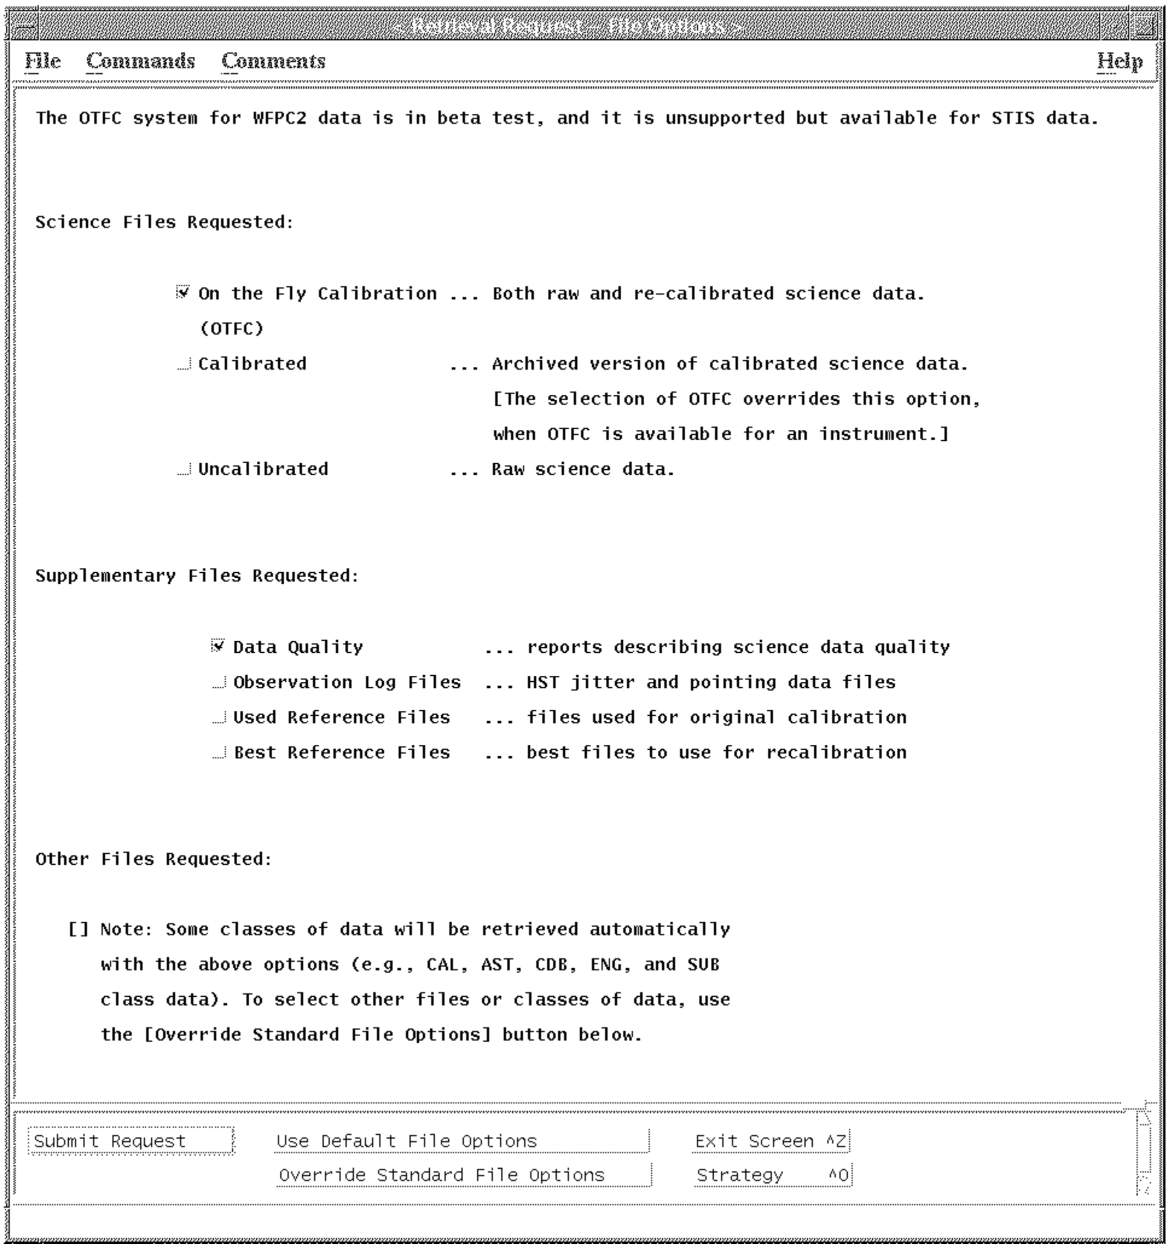

Figure 8.32: <Retrieval Request - File Options> Screen

<STIS OTFC > Screen

The <STIS OTFC> screen can be used to extract more information about recalibration of STIS data, including the date the software was last changed and the latest date of any header keyword update for any dataset (to allow the user to determine if their previously calibrated data need to be requested again through OTFC). Detailed information about each recalibration step, including the relevant file names, is also given.

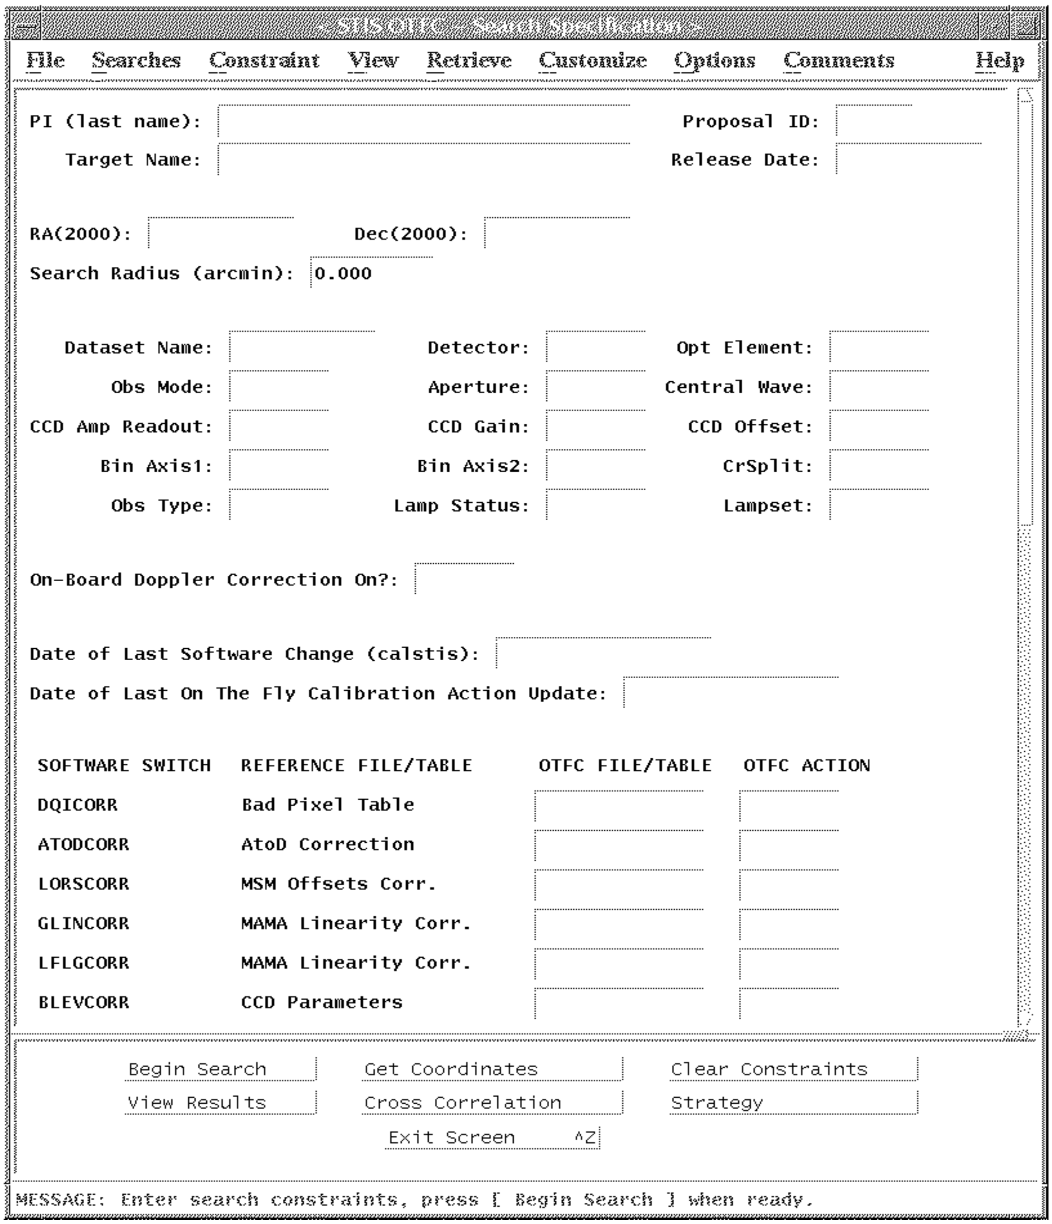

Figure 8.33: <STIS OTFC - Search Specification> Screen

<WFPC-2 OTFC> Screen

The <WFPC-2 OTFC> screen can be used to extract more information about recalibration of WFPC-2 data, including the date the software was last changed and the latest date of any header keyword update for any dataset (to allow the user to determine if their previously calibrated data need to be requested again through OTFC). Detailed information about each recalibration step, including the relevant file names, is also given.

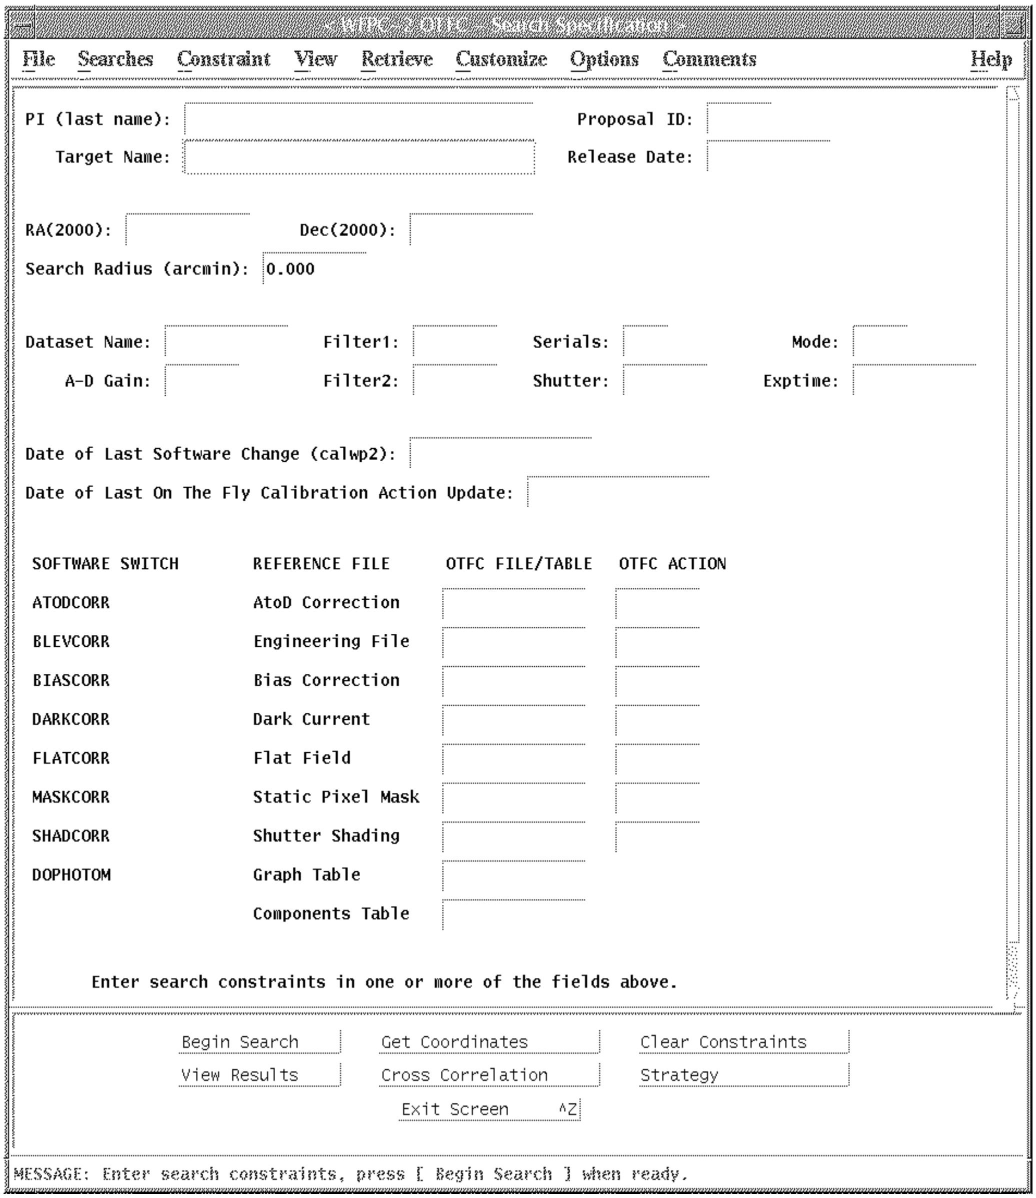

Figure 8.34: <WFPC-2 OTFC - Search Specification> Screen

Archived Files Screens

StarView provides several screens that let you search the HST catalog for information about the files that are stored in the HST archive. For example, you can find out when a dataset was archived, determine which files are available for the different archive classes (in addition to the usual CAL class; see Chapter 9 for details), or read the data quality comments associated with the data files for a given observation. The <Files Search> screen also allows operators to identify the optical disk on which a file is located.

<Dataset Name> Screen

The <Dataset Name Search Specification> screen is used to search the HST Catalog for archiving and distribution information for individual datasets. The results of your search request are returned on the <Dataset Name Search Results> screen.

In particular, you can search for (and mark for retrieval) datasets by dataset name, archive class, or release date. It is especially helpful to use this screen to find non-CAL class datasets (i.e., ASA, AST, CDB, DMP, EDT, ENG, GSP, ORB, SUB, or SUO).

This screen is also used by archive operators to search for datasets by version number, creation date, or archive date

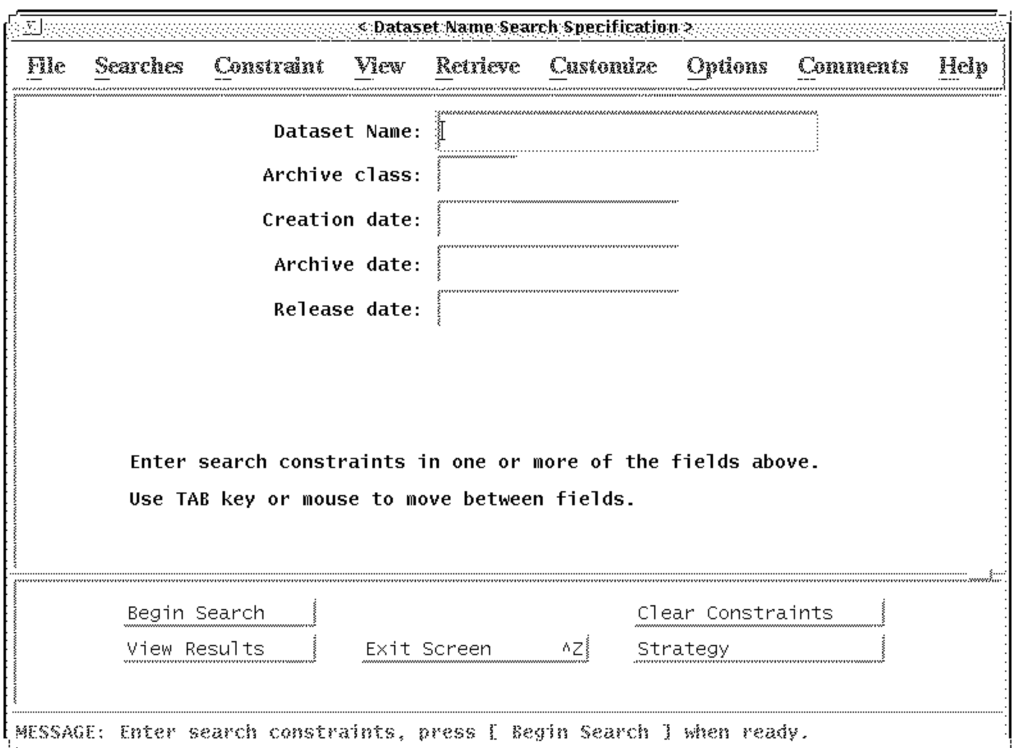

Figure 8.35: <Dataset Name> Screen

<Engineering Screen>

The <Engineering Timeline> screen searches for ephemeris data, engineering and engineering subset data as well as mission schedules, and mission timelines. Typically, you will wish to find a specific type of data corresponding to a typical time period. To do this, first qualify on “DATA TYPE”, entering

- ENG — for engineering data
- MSC — for mission schedule data
- MTL — for mission time lines
- ORB —for ephemeris data
- SUB —for engineering subsets

Next, qualify on the range of dates you are interested in by entering the earliest and latest times in the “DATA START TIME” and “DATA STOP TIME” fields with less than and equal to signs respectively, for example

```
“DATA START TIME” > 04/27/90 05:00:00
“DATA STOP TIME” < 04/27/90 08:00:00
```

Once you have found datasets of interest, you can mark them for retrieval and proceed to submit your retrieval request.

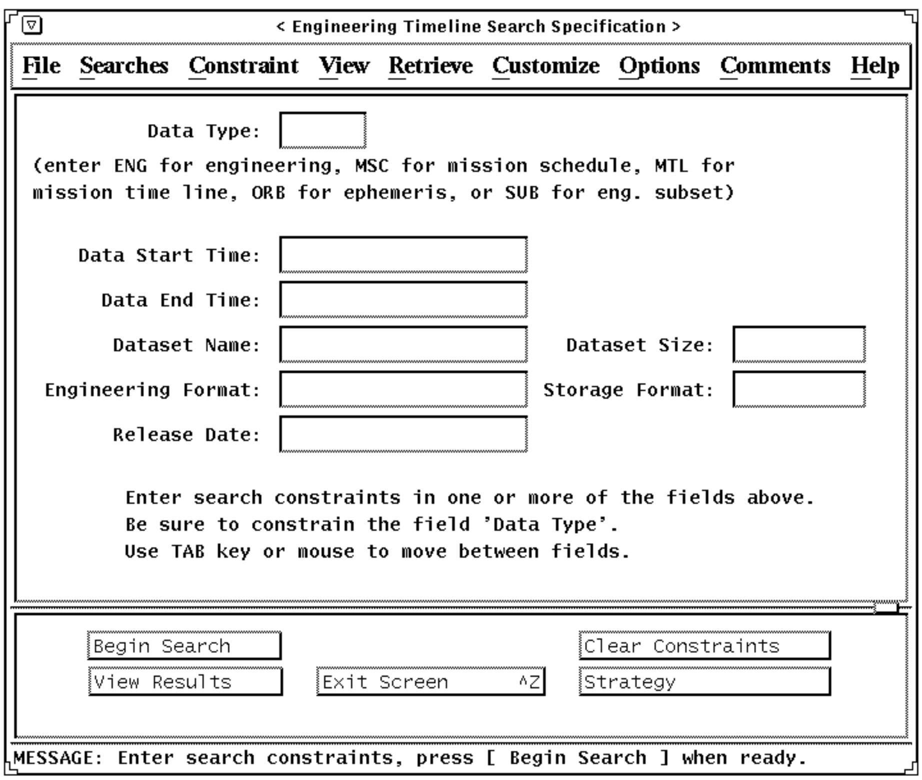

Figure 8.36: <Engineering Screen>

<Files Search> Screen

The <Files Search Specification> Screen is mostly geared to internal users who are retrieving specific files by dataset name or by archive class. It is particularly useful to users of non-CAL archival classes of data. This form is also used by archive operators in order to track down the physical location of datasets on optical disks.

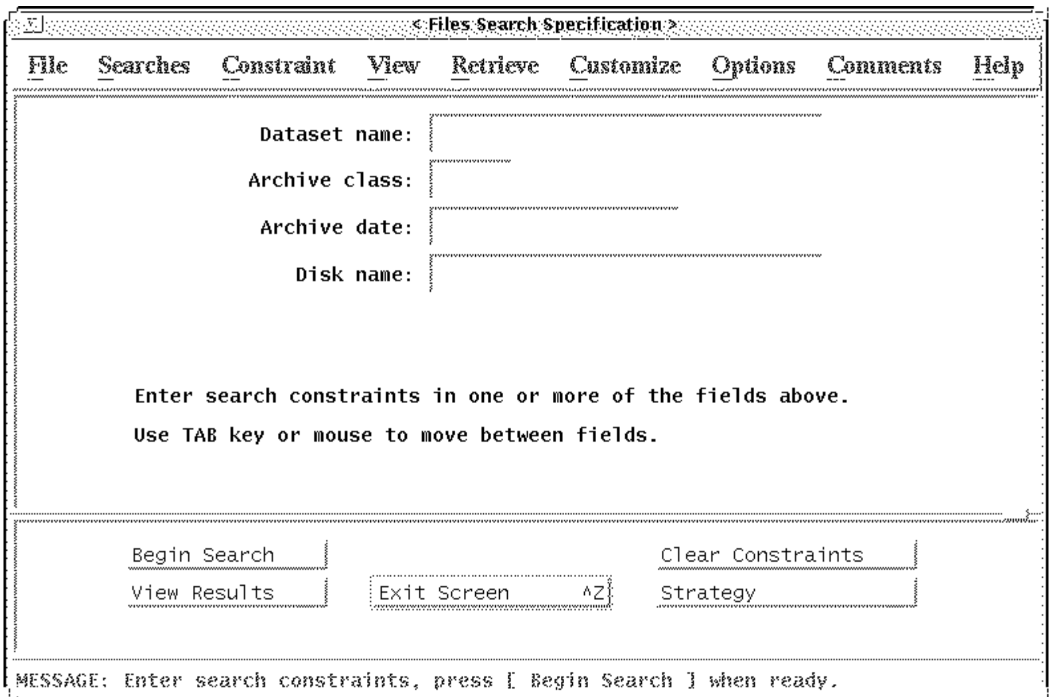

Figure 8.37: Files Search Screen

Archive Retrieval Screens

StarView provides several screens that take you step-by-step through the archive retrieval process. This process includes reviewing your list of marked datasets, selecting which files you want to retrieve, entering your archive user name and password, selecting distribution media and data format options, and finally submitting your retrieval request to the archive request handler for processing. The archive retrieval screens are presented and described in this section. See Chapter 4 for procedures on using these screens.

<Archive Retrieval> Screen

You can use this screen to review and submit the list of datasets that you have marked for retrieval. You can add additional datasets to this list, remove datasets from the list, or write the list to a file prior to submitting your retrieval request to the HST Archive for processing.

This screen displays most of the scientifically useful catalog information about the exposures that you have selected for retrieval. This information is presented in table format. There are a few additional fields that are available for viewing off the screen to the right.

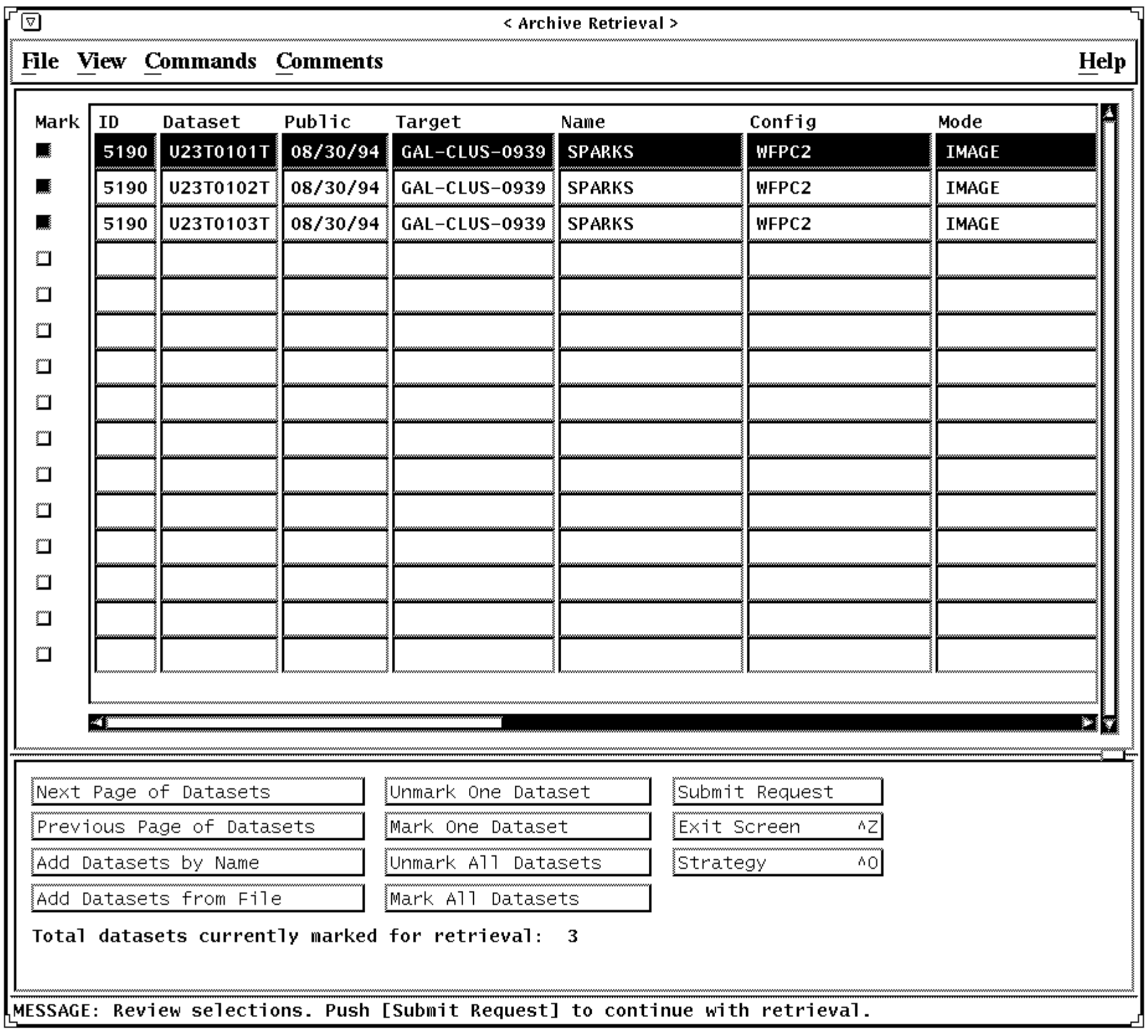

Figure 8.38: <Archive Retrieval> Screen

<Retrieval Request - File Options> Screen

You can use this screen to select the types of science files that you want to retrieve. You can retrieve the calibrated science data files (default), the uncalibrated science data files, and/or the data quality report files (default). Selecting any of the options on this screen will not affect any of the non-science data files that you may have previously marked for retrieval.

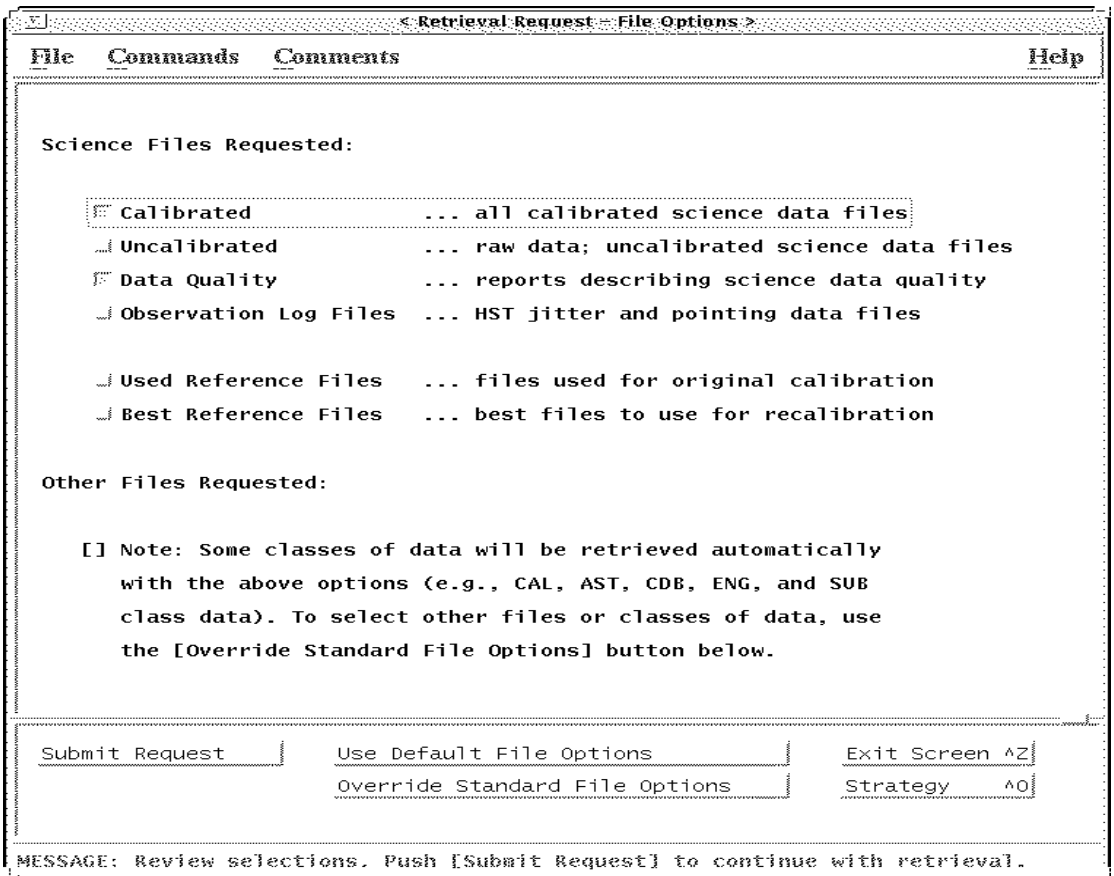

Figure 8.39: <Retrieval Request - File Options> Screen

<Retrieval Request - Media Options> Screen

You can use this screen to enter your archive user name and password, and to select the media type for your retrieved data.

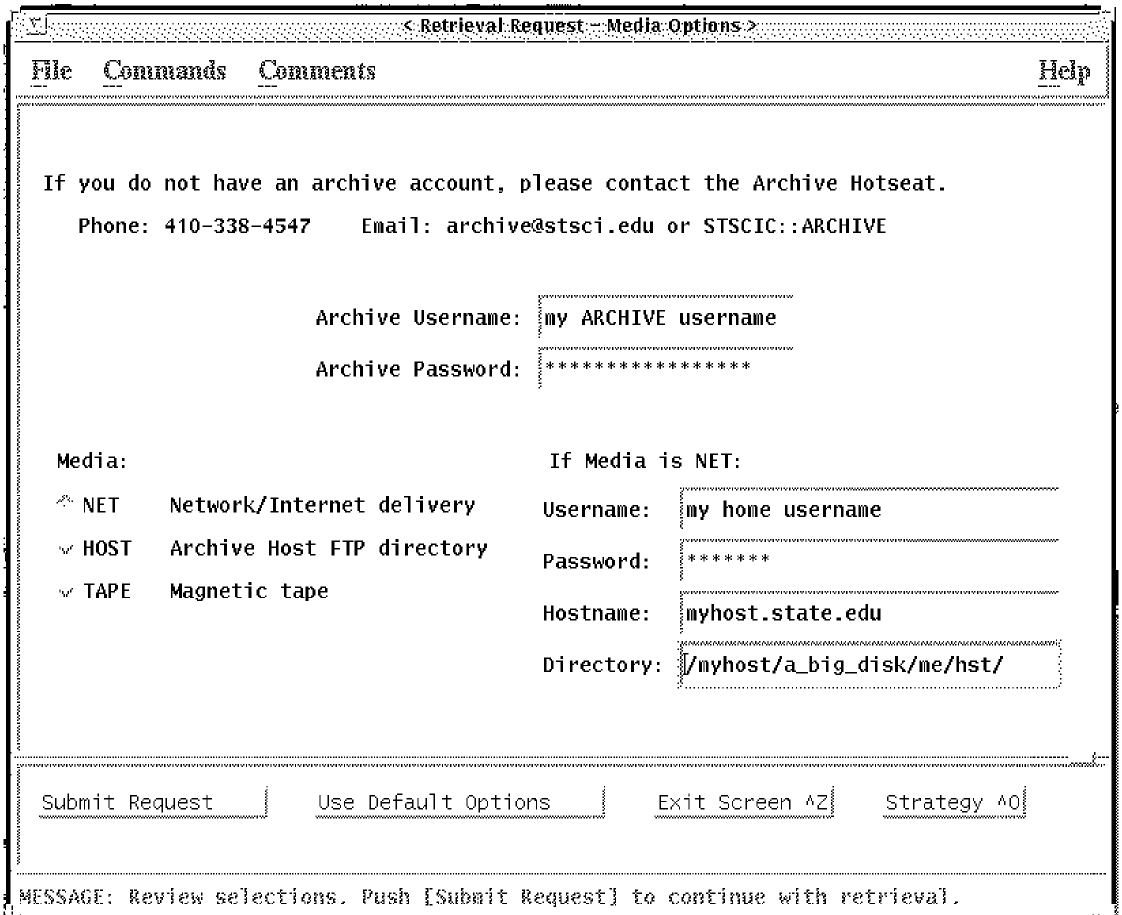

Figure 8.40: <Retrieval Request - Media Options> Screen

<Retrieval Request - Override File Options> Screen

You can use this screen to select a more general variety of files for retrieval. The normal StarView defaults, which you can override on this screen, are to retrieve the calibrated science files and the data quality report files. On this screen, you can select any available version of archived files, files from any archive class, and files with any file extension. For example, you can use this screen to select files that do not belong to the CAL archive class (e.g., FGS/astrometry data files or engineering files), or you can use this screen to select CAL class files that are not among those selected by the defaults identified on the preceding retrieval request screens. In nearly all cases, you will want the most recent version of a file (selected automatically by Version=0).

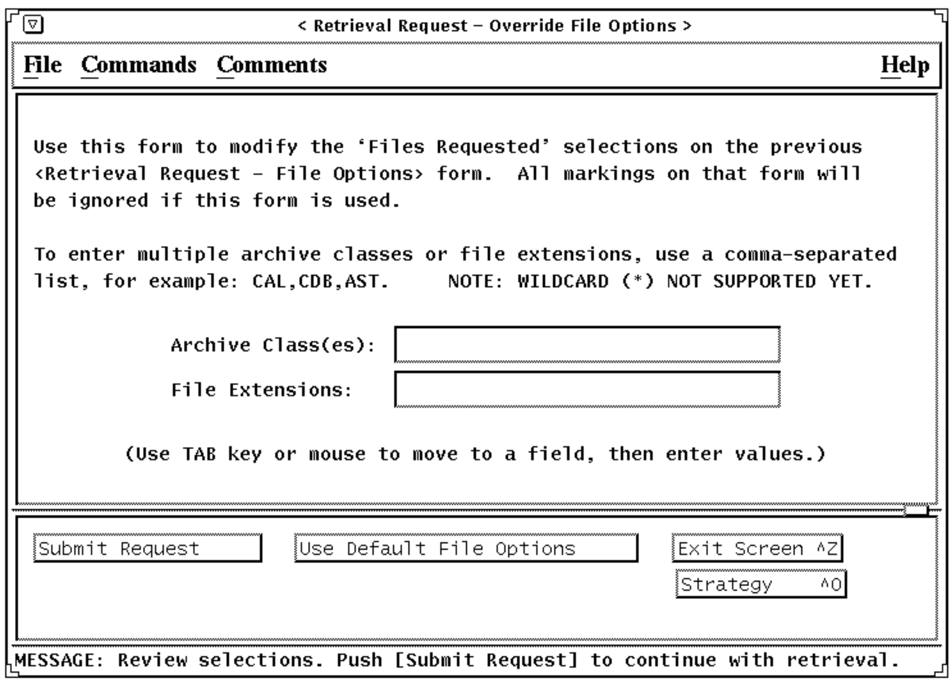

Figure 8.41: <Retrieval Request - Override File Options> Screen

StarView Environment Screens

StarView provides several screens that let you customize the environment in which you are operating StarView. You can set up, save, and restore your own defaults for archive retrieval options, date/time formats, output coordinate systems, and user defaults. The StarView environment screens are presented and described in this section. See Chapter 7 for procedures on using these screens.

<Archive Retrieval Defaults> Screen

This screen lets you modify some of the options used for requesting datasets from the archive. You can change either your default user name and password, the default files that are retrieved when you mark datasets for retrieval, the default distribution medium, or any combination of these items.

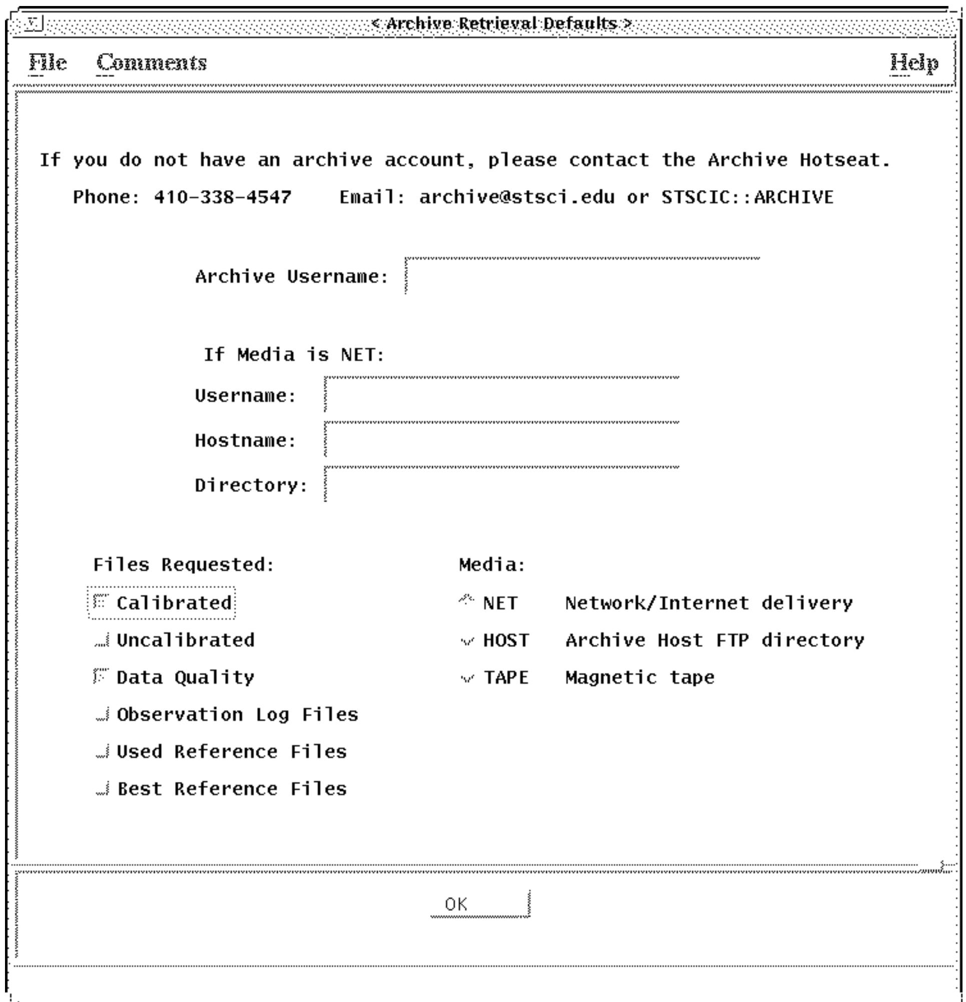

Figure 8.42: <Archive Retrieval Defaults> Screen

<Date/Time Formats> Screen

This screen lets you modify the formats in which dates and times are displayed. You can change the format for any of these: month, day, year, hour, minutes, or seconds. If you do want to change the default date/time formats, then it is best to experiment with the different options on this screen to see which ones you like. For example, you can choose to see times like “12:34:56” or like “12h34m56s.”

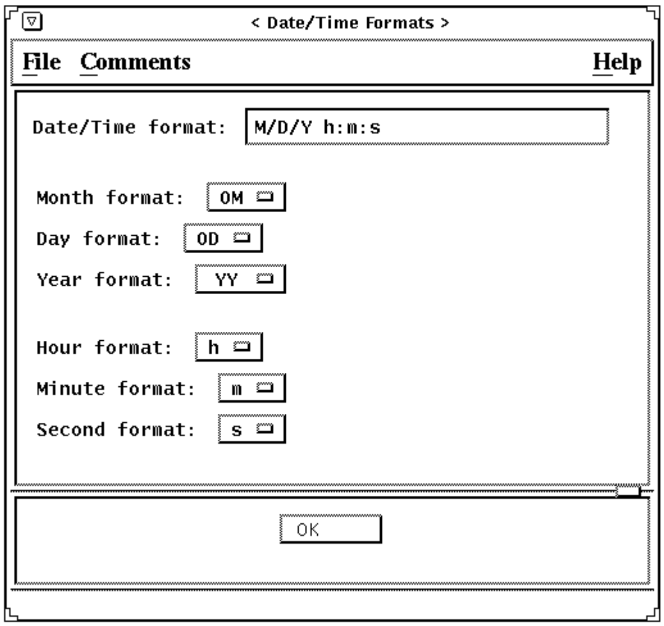

Figure 8.43: <Date/Time Formats> Screen

<Output Coordinates> Screen

This form lets you modify the format in which positional coordinates are displayed. Positional coordinates include RA, longitude, Dec, and latitude. You can change the coordinate system (Equatorial, Ecliptic, Galactic, or Supergalactic), the equinox, the RA/Longitude format, the Dec/Latitude format, or any combination of these. Note that these changes will not affect the field labels on the StarView search specification and results screens. They will still say “RA(2000)” and “Dec(2000)” (or simply “RA” and “Dec” in some cases), even though the catalog values attached to those fields will now be displayed according to your new chosen format.

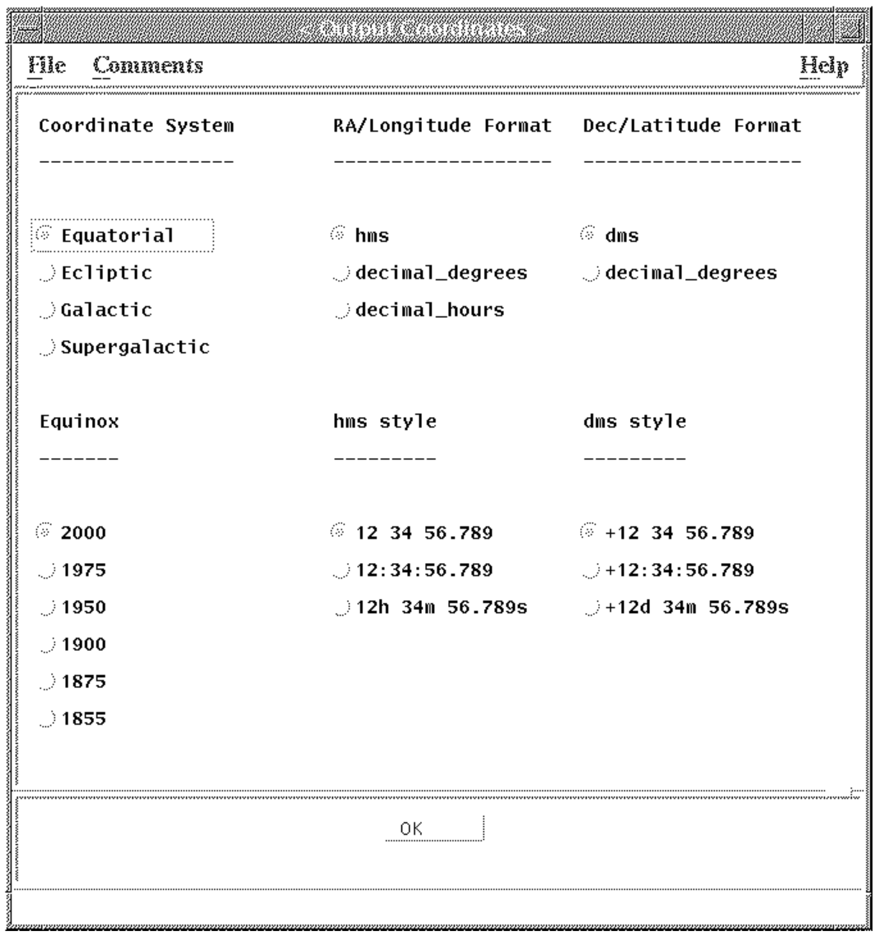

Figure 8.44: <Output Coordinates> Screen

<User Defaults> Screen

This form lets you modify some of the StarView system defaults: the initial form name, catalog, menu options, and basic display formats. For example, you can change the default character string format from uppercase to lowercase, or you can change the default floating number format from decimal format to scientific notation. You can also change the default radius for circular-area searches around specified target positions, and you can change between the SIMBAD and NED coordinate resolvers. Under normal circumstances, however, it should not be necessary for you to change any of the other defaults on this environment screen.

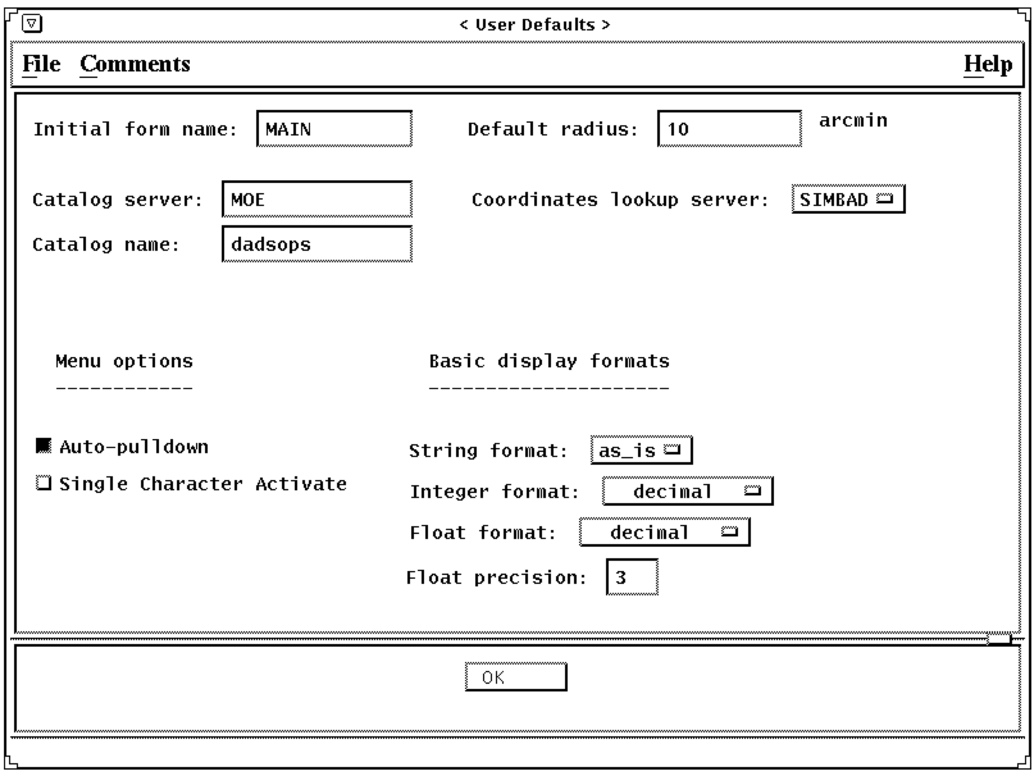

Figure 8.45: <User Defaults> Screen

StarView Utility Screens

StarView provides several utility screens that assist you in using the system, in getting help, in navigating around, in setting up special customized catalog searches, or in viewing and writing search results as a table. These screens are described in this section. You will not need to access all of these utilities to use StarView for simple catalog searches and data retrieval. However, they do represent the range of StarView capabilities: from the introductory <Welcome> and <Help> screens to the sophisticated <SQL Editor> and <Custom Query> screens.

<Custom Query> Screen

This screen lets you construct your own custom queries (i.e., searches) of the HST catalog. Typically, you would do this when the predefined StarView screens do not have the information (i.e., the catalog fields) that you are interested in. With the custom query feature, you can choose to display a wide variety of catalog information on a single screen, picking and choosing from among all of the available fields in the HST catalog. This powerful feature of StarView is described in detail in Chapter 6.

MESSAGE: Filter and Sort to trim list of available attributes; Mark to select.

Figure 8.46: <Custom Query> Screen

<Help> Screen

Help text for a specific topic is displayed in the data area of this screen. There can be many screenfuls of help text. Additional help topics that are related to the displayed topic are listed in the “See Also” box. Both the help text area and “See Also” area are vertically scrollable. See Chapter 4 for procedures on using this screen.

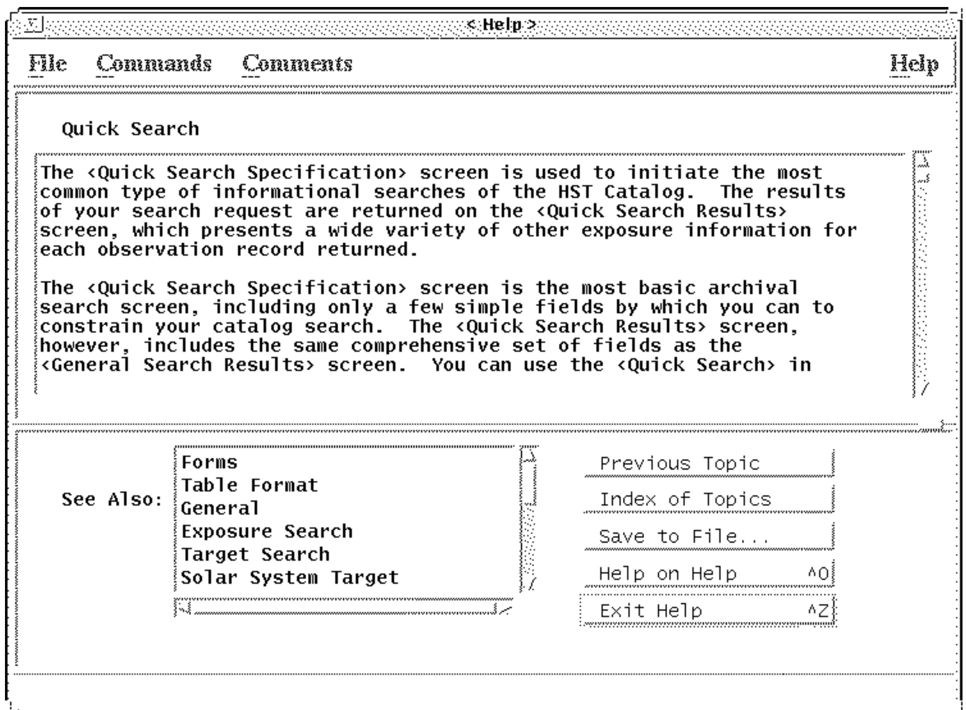

Figure 8.47: <Help> Screen

<Other Searches> Screen

This screen presents a user-selectable list of the predefined search screens. You can use this screen to select one of the listed searches. See Chapter 4 for procedures on using this screen.

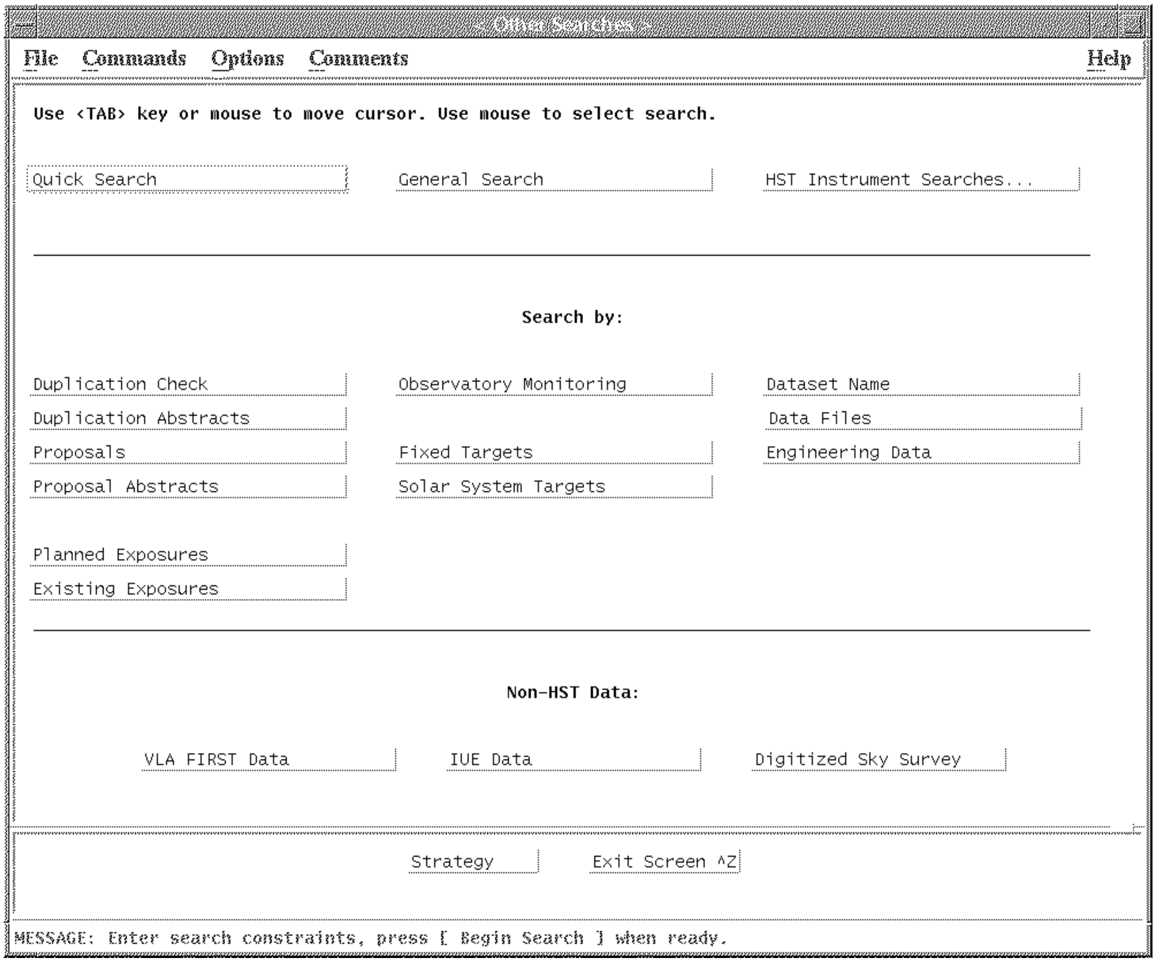

Figure 8.48: <Other Searches> Screen

<SQL Editor> Screen

This screen lets you display and modify the SQL (Structured Query Language) for the current query or for a set of SQL statements copied from an external file. You can also enter your own SQL statements on the screen. Typically, you would do this when you want to make specialized queries of the HST catalog (e.g., to list all unique values of a specific field in the catalog or to impose a complex set of conditions on a catalog search). This special feature of StarView is described in detail in 6. Only those who are experienced in SQL programming should use this feature.

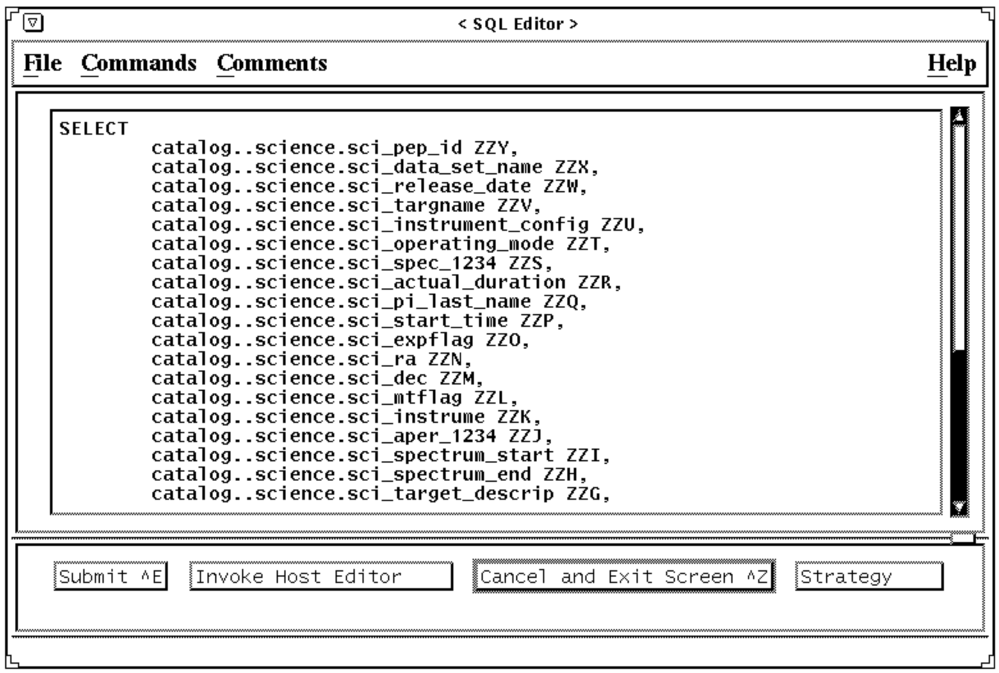

Figure 8.49: <SQL Editor> Screen

<Table Export> Screen

This screen lets you specify the options to use when writing (i.e., exporting) search results to an external file. Your search results are stored automatically by StarView in an internal file, which can then be copied to an external file for your own use. For example, you may wish to store the list of all observations for a certain class of objects in a file that may be used by another archive system to see if there are any target overlaps. You can write this file in ASCII or FITS format, and you can include column headings or other data description information in the file if you wish. This screen tells you how big (in Kbytes), how wide (in bytes), and how long (in records) your output file will be.

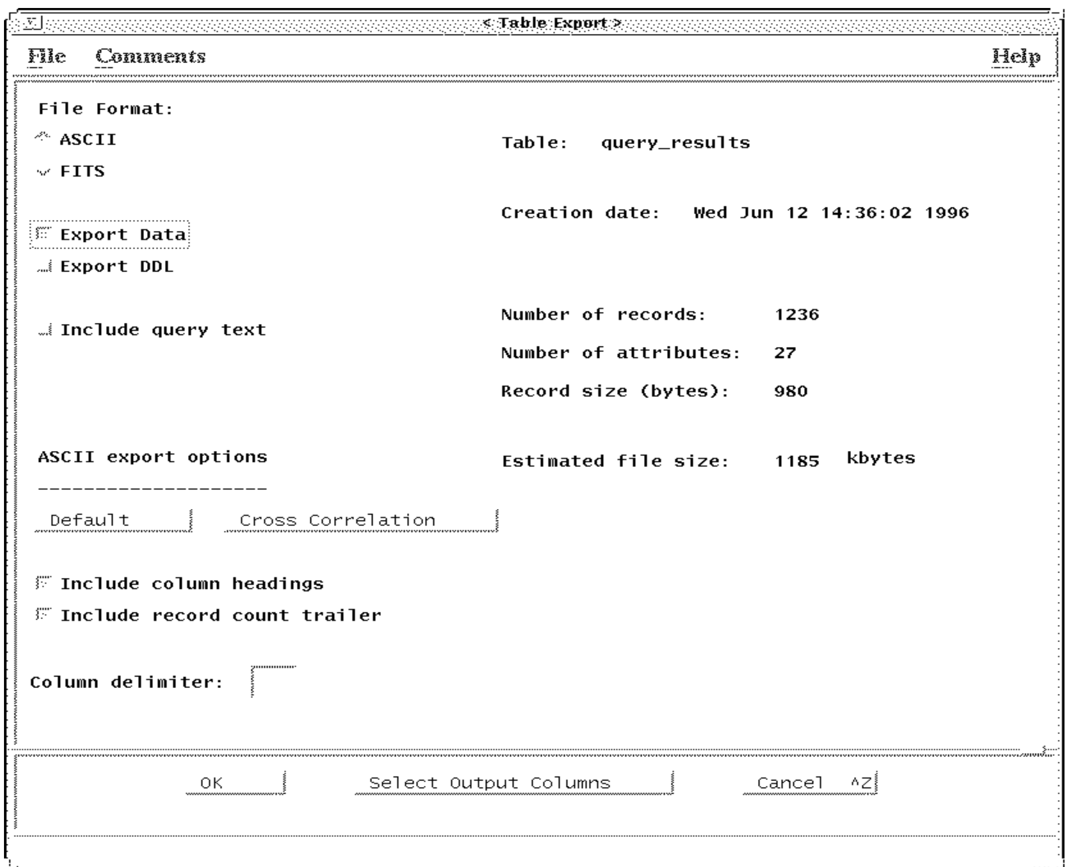

Figure 8.50: <Table Export> Screen

<Table Format> Screen

You can use this screen to initiate searches of the HST catalog and to view the results of catalog searches in a multi-record format. This lets you see a significant portion of your search results at one time. The fields on the <Table Format> screen vary, depending on the preceding screen displayed. See Chapter 4 and 7 for procedures on using this screen, including mouse commands that allow you to rearrange columns, delete columns, and alter column widths.

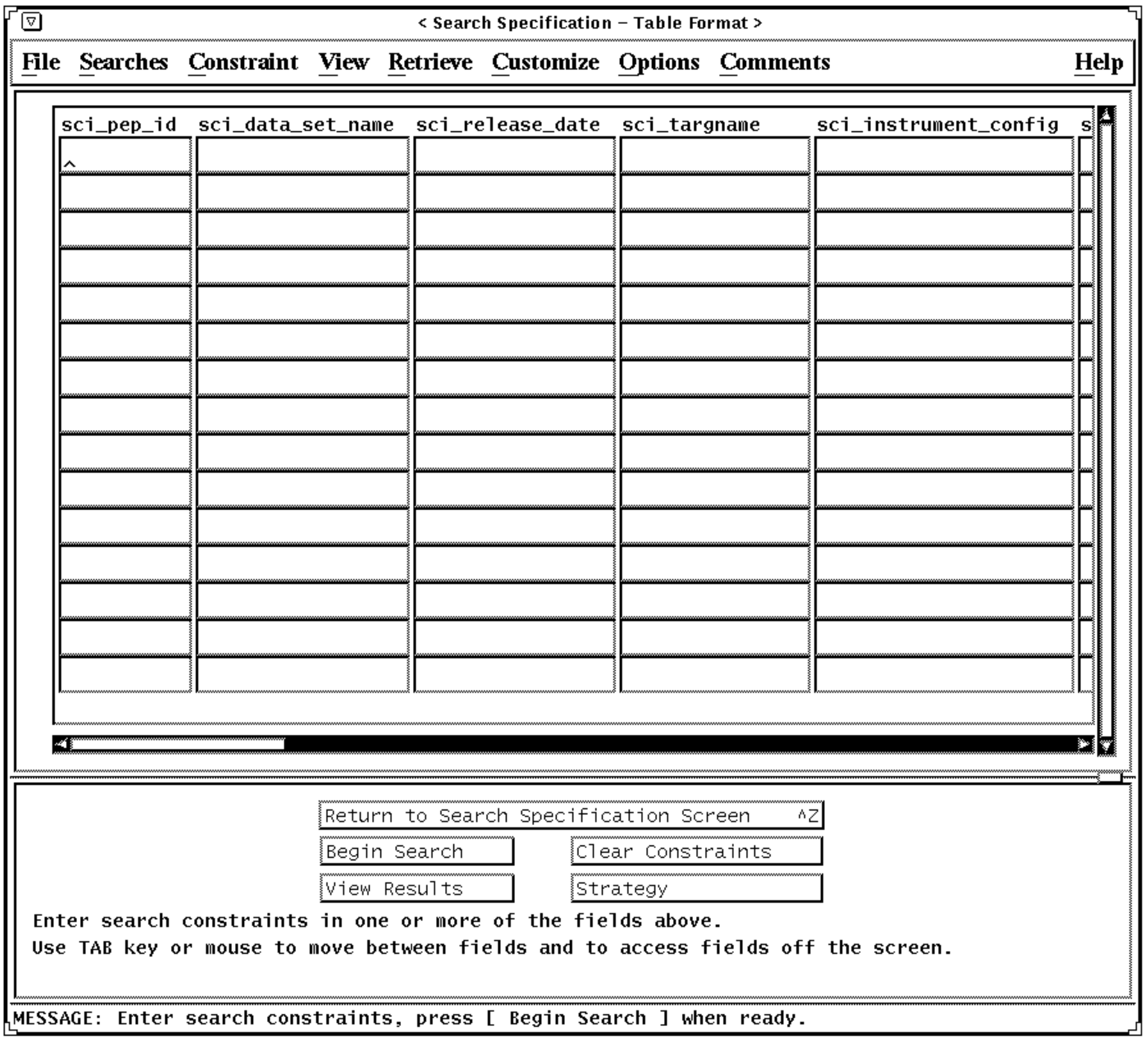

Figure 8.51: <Search Specification - Table Format> Screen

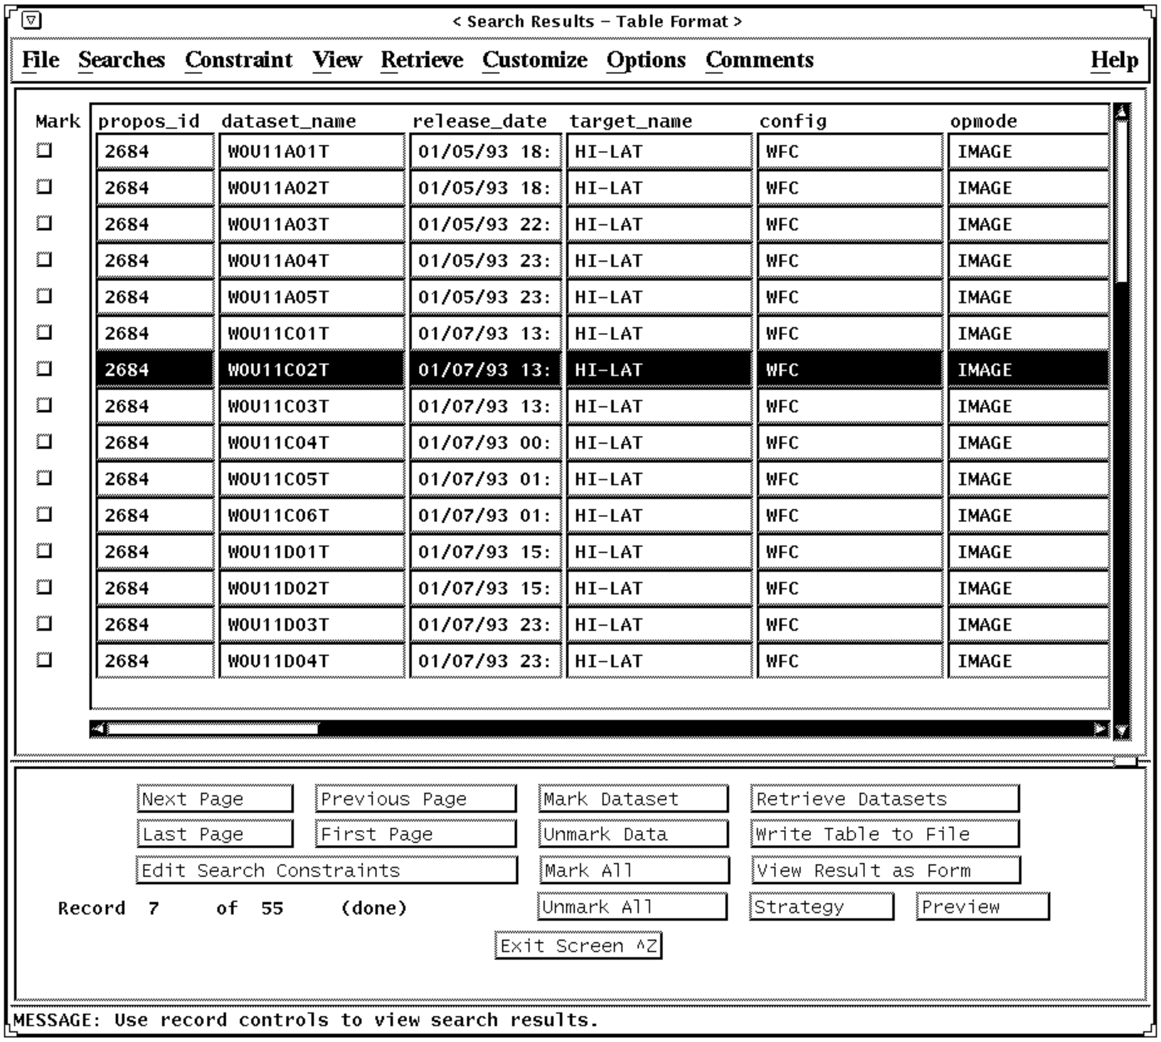

Figure 8.52: <Search Results - Table Format> Screen

<Welcome> Screen

This screen is the first screen that you see when you enter StarView, and it is the end of the chain of screens that are displayed whenever you enter multiple “Exit Screen” commands from any of the other StarView screens. This screen contains both informational messages and instructional text. It is also used to present important message-of-the-day notices. Chapter 4 describes various aspects of this screen and how to navigate around StarView screens in general.

The <Other Searches> screen (see page 206) is only accessible through the <Welcome> screen. In addition, all of the basic StarView commands, utilities, and features are accessible from the menus on the <Welcome> screen. Hence, this screen can be used as the starting point for nearly all StarView operations: catalog searches, data retrieval, checking retrieval status, sending comments to the archive hotseat, getting help, etc.

When you start up StarView, it will take a minute or so to get ready.

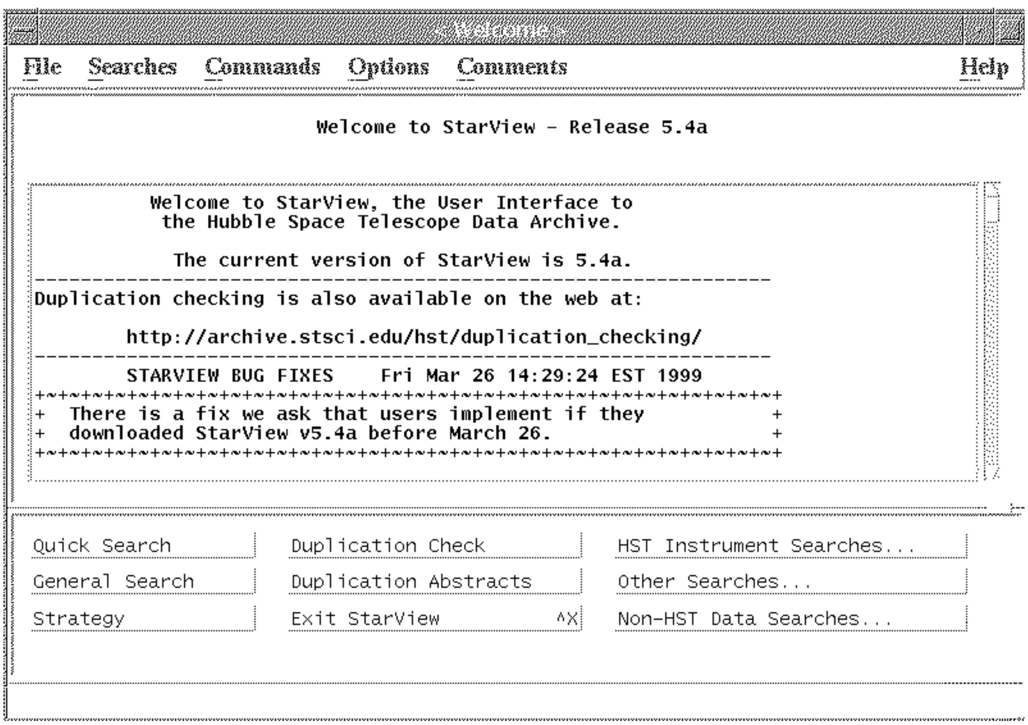

Figure 8.53: <Welcome> Screen

9 Data in the HST Archive

In This Chapter...

This chapter explains how archived Hubble Space Telescope (HST) data are organized, and describes the conventions used to name classes and files in the HST archive.

Overview

Archived HST data are organized according to archive classes that delineate broad categories of data (e.g., science data, calibration data, HST mission schedules, engineering data, ephemeris data, and guide star data). Each of these archive classes contains a specific set of data files. The archive class for a set of files then determines, among other things, the proprietary period of those data files. For science data, the types of files included in the observation dataset depend on the scientific instrument. Each HST observation is identified by a unique dataset name, which becomes the root name for the files in that dataset. Each file then takes on a unique file extension according to the content of the file. There is therefore a list of valid file extensions for each archive class and instrument. When retrieval requests are submitted to the archive request handler, the archive system determines which files to retrieve based upon the class and source of the data being requested.

According to the above prescription, the files stored in the archive all have unique file names, the exception being that recalibrated and reprocessed observations may generate files with names identical to those produced by the original calibration or processing. Such files are distinguished by their generation dates. Typically, only archive operators at the Space Telescope Science Institute (STScI) will be concerned about these different versions.

Archive researchers should use only the most recent versions of the files, which is the default for retrievals.

In the sections below, we describe the conventions used to name the different data files and archive classes in the HST archive.

File Names

File names consist of two parts: the root name and the extension. The way the root name is derived depends on the type of file (its Archive Class: see page 220). For science data, the extension identifies the type of data in a particular file, as each observation may have many associated files with the same root name.

Most of the files that you will encounter in the archive are FITS files containing the science data for an observation. Science data files are described in the next section. There are also non-science data consisting of unidentified science data files, dump data files, engineering data, etc. File naming conventions for these non-science file types are not of interest to the typical archive user. These can be found on the WWW at `http://sesd.stsci.edu/~hopkins/non-science-data.htm`.

Science Data Files

For any HST observation, the STScI data processing pipeline produces not just one data file, but an entire set of files. The FITS files contain the science data for an observation. All files for a particular observation have the same root name. The type of data in each file is identified by its extension.

At a minimum, for each observation the OPUS pipeline produces a standard header packet file, a science data file, and its corresponding data quality file; and stores appropriate engineering data and ancillary information in the unique data log file (UDL).[1] The standard header packet (SHP) contains telemetry data, spacecraft operation data, and instrument-specific data. The UDL contains the command values for each instrument, such as exposure parameters and aperture commands. For the STIS and NICMOS instruments, both the SHP and UDL information are contained in the SPT file. The science data files contain the observed image stored as a FITS file. The number of science data

1. For the Wide Field Planetary Camera (WFPC) and WFPC-2, an extracted engineering data file is produced instead of the unique data log (UDL).

files, the size of those files, and the number of dimensions vary across instruments and observing modes. Each science data file has an accompanying data quality file to identify bad data values in the science data. In addition to these files, additional files are typically produced by the calibration software in the OPUS pipeline.

The dataset root name consists of 9 characters of the form

`IPPPSSOOT`

The IPPPSSOOT file naming convention is applied by OPUS and is defined in Table 9.1. We note that this convention applies only to science data files (ASN, AST, CAL, and PDQ classes: see Table 9.13) and observation log (OMS) files.

Character	Meaning
`I`	Instrument Used, will be one of: ***F*** - Fine Guidance Sensors ***J*** - Advanced Camera for Surveys ***N*** - Near Infrared Camera Multi Object Spectrograph ***O***- Space Telescope Imaging Spectrograph ***U*** - Wide Field Planetary Camera-2 ***V*** - High Speed Photometer ***W*** - Wide Field Planetary Camera ***X*** - Faint Object Camera ***Y*** - Faint Object Spectrograph ***Z*** -High Resolution Spectrograph
`PPP`	Program ID; can be any combination of letters or numbers (46,656 combinations possible)
`SS`	Observation set ID; any combination of letters or numbers (1,296 possible combinations)
`OO`	Observation ID; any combination of letters or numbers (1,296 possible combinations)
`T`	Source of transmission (RSDP environment) ***J***- OMS data ***R***- Real time (not recorded) ***T*** - Tape recorded ***M*** - Merged real time and tape recorded ***N*** - Retransmitted merged real time and tape recorded ***O*** - Retransmitted real time ***P*** - Retransmitted tape recorded 0 - (zero) Primary association product (NICMOS/STIS/ACS) 1-8 NICMOS background association products

Table 9.1: IPPPSSOOT Root File Names

Common Extensions for Instrument Data Files

File name extensions and their contents vary from instrument to instrument. The common extensions for science data files and descriptions of their contents are given in Tables 9.2 through 9.12. For more detailed descriptions of the files and their contents, see the individual instrument handbooks or data product guides (see page 14).

Extension	File Type
_a1f.fits	FGS1 group data file
_a2f.fits	FGS2 group data file
_a3f.fits	FGS3 group data file
_dmf.fits	Science data and proposal information header file. Also, database indices for astrometry and engineering data

Table 9.2: Extensions for FGS Astrometry Data Files

Extension	File Type
_d0f.fits	Uncalibrated data file
_shf.fits	Standard header packet
_q0f.fits	Data quality file[a]
_ulf.fits	Unique data log
*.trl	Trailer file

a. _q*f.fits for FOS.

_c2f.fits	Calibrated science data: analog star
_c3f.fits	Calibrated science data: analog sky

Table 9.12: Extensions for HSP Calibrated Data Files

Archive Classes

Table 9.13 describes the classes of data files in the HST Archive. Most archival researchers will need only the CAL, ASN, AST, and PDQ files.

Class	Contents
ACC	STIS MAMA Accumulated Image Data
ANC	Ancillary data; includes POD files (raw science data)
ASN	Association table (NICMOS, STIS, ACS)
AST	Astrometry data from the Fine Guidance Sensor (FGS)
CAL	Calibrated and uncalibrated science files
CDB	Calibration reference files
CTB	Calibration reference tables
DIA	Engineering NICMOS, STIS and ACS diagnostic FITS memory dumps
DLG	DADS log files
DMP	On-board computer memory dumps (HSP, FOC, FOS)
EDT	Raw edited versions of science files, used by the Post Observation Data Processing System (OPUS) to generate CAL files
ENG	Reconstructed engineering telemetry data
MSC	Mission schedules
MTL	Mission Timeline Data
OCX	Observer comment files
OMS	Observation log files (including HST jitter motion)
ORB	Definitive ephemeris files for HST orbit
PDQ	OPUS data quality comment files
PRB	Problem science data
SMS	Science mission specification files (the command files used to control the observations)
SUB	Engineering subset files
VLA	VLA FIRST data (Faint Images of Radio Sky at 20 cm)

B HST Archive Database Description

In This Appendix...

This appendix describes the database structure of the HST archive. It should be particularly useful to those who find the standard StarView screens too limited for a required search and therefore need to design a custom query.

There are three separate databases used by the archive. These are the Catalog, CDBS (Calibration Data Base) and Proposal databases. Each database is a collection of tables which can be thought of as two dimensional arrays. The rows are the data attributes (for example exposure time or instrument name) and the columns are the datasets referenced by the database. The user specifies the values of the attributes which will be considered a match during a search.

The Catalog database contains information on scientific and engineering datasets. Users interested in finding completed scientific observations that match particular criteria (instrument and filter used, target type etc.) will primarily use this database. Because a search across many different tables can be time consuming, a special table has been added to the Catalog database which contains many of the most frequently contained attributes from the other Catalog tables. Users should look first at this “science” table to see if an attribute of interest can be found there. The Catalog database also contains the _ref tables, which give information on the calibration files recommended for use with a particular observation.

The Calibration Data Base provides information on the raw data used to create the recommended reference files. These tables will primarily be of use to STScI staff and those researching particularly subtle calibration issues.

The Proposal database contains information on observations which have been approved but not necessarily taken. This information is gathered from the Phase II proposals of General Observers and from the Phase II and observing proposals of Guaranteed Time Observers, and is updated when observations are taken.

Note that we do not give here details of the HST instrument tables. These, and additional information on data files from the Observatory Monitoring System, can be found on the WWW at `http://archive.stsci.edu/keyword`. The WWW page can also be used to generate a schematic header and view the overall database structure.

Catalog

The following tables are included in the Catalog database:

- **archive_data_set_all**: Provides DADS system information relevant to the archival status of a particular dataset. Primarily intended for the use of STScI staff. Page 231.
- **archive_extensions**: Lists the particular file extensions for the datasets in **archive_data_set_all**. Page 233.
- **assoc_member:** Gives detailed information on each association (members, datasets) and describes the role each member played in it. Page 234.
- **assoc_orphan:** Includes exposures which were supposed to become members of an association but never made it. Page 234.
- **assoc_status**: Gives information on the status of an association. Page 234.
- **fgs_data**: The primary table for information on the instrument configuration used for a particular FGS observation.
- **fixed_target**: Information on a particular fixed (i.e., non-solar system) target (position, proper motion, estimated magnitude, etc.) Page 235.
- **foc_data**: The primary table for obtaining information on the instrument configuation used in an FOC observation.
- **foc_ref_data**: Recommended reference files for calibrating FOC datasets.
- **fos_data**: The primary table for obtaining information on the instrument configuration used in an FOS observation.
- **fos_ref_data**: Recommended reference files for calibrating FOS observation datasets.
- **hrs_data**: The primary table for obtaining information on the instrument configuration used in an HRS observation.

- **hrs_ref_data**: This table provides information on the HRS calibration files recommended for use in the reduction of a given dataset.
- **hsp_data**: The primary table for obtaining information on the instrument configuration used in an HSP observation.
- **hsp_ref_data**: This table provides information on the HSP calibration files recommended for reducing a given dataset.
- **moving_target_position**: Position information on moving (solar-system) targets. Page 235.
- **nicmos_a_data**: The primary table for obtaining information on the instrument configuration used in a NICMOS observation. Given its size, this table is split in three.
- **nicmos_b_data**: Same as **nicmos_a_data**.
- **nicmos_c_data**: Same as **nicmos_a_data**.
- **nicmos_ref_data**: This table provides information on the NICMOS calibration files recommended for reducing a given dataset.
- **nicmos_science**: Association information for NICMOS data which could not make it into the science table.
- **nicmos_times:** Selected information from MULTIACCUM data.
- **oms_data**: Contains values extracted from observation logs. Observation logs have the same names as their corresponding science exposures. Page 236.
- **oms_summary**: same as **oms_data** except this is the information that pertains to the sets of observation logs that correspond to an association. Page 238.
- **otfc_bypass_calibration:** This table includes datasets which should *not* be recalibrated during On-The-Fly calibration (OTFC) requests (see Page 135), for example because they gave problems when they first went through the OPUS pipeline. Page 241.
- **otfc_keyword_repair:** This table controls the changes to keywords and their values, as part of the OTFC service. Page 241.
- **pdq_summary**: contains data quality information extracted from the PDQ file. Page 243.
- **proposal**: Proposal ID, investigator information and SOGS program ID (see the proposal database for a wider variety of proposal information). Page 243.
- **scan_parameters**: Information on the observational details of a scanned observation: Page 243.

- **science**: This table is a composite of frequently used information found in a number of other tables. By combining this information into a single table, the speed of searches through the archive is improved. The table from which each attribute is taken is given, along with the attribute definition. Page 244.
- **shp_data**: The standard header packet contains header keywords common to all observations.Page 247.
- **stis_a_data**: The primary table for obtaining information on the instrument configuration used in a STIS observation. Given its size, this table is split in three.
- **stis_b_data**: Same as **stis_a_data.**
- **stis_c_data**: Same as **stis_a_data.**
- **stis_grand_mama**: This table provides information on the grand_mama, an accumulated image of all the counts that the Multi-Anode Microchannel Array (MAMA) detector has recorded over time.
- **stis_ref_data**: This table provides information on the STIS calibration files recommended for reducing a given dataset.
- **stis_science**: Association information for STIS data which could not make it into the science table.
- **target_keyword**: Target keyword information. Page 252.
- **target_synonym**: Target synonym information. Page 253.
- **wfpc_data**: Information on the state of the WF/PC which is identical for all four chips (e.g., shutter open and close times, filters, reference files used).
- **wfpc_group_data**: Information on the state of the WF/PC which differes from chip-to-chip (e.g., bias levels, orientation, pixel values).
- **wfpc_ref_data**: This table provides information on recommended WF/PC calibration files.
- **wfpc2_primary_data**: This table and the associated **wfpc2_secondary_data** table contain information related to the state of the WFPC2 and the data obtained (e.g., bias values, temperature).
- **wfpc2_ref_data**: This table provides information on recommended WFPC2 calibration files.
- **wfpc2_secondary_data**: This table the **wfpc2_primary_data** table contain information related to the state of the WFPC2 and the data obtained (e.g., background level, histogram width, and skewness).

Table B.1: The *archive_data_set_all* Table

Field	Description	Source
ads_access_time	Date and time when this data set was most recently accessed. (Note: This is internal distribution information for DADS.)	INTERNAL
ads_archive_class	The archive class for this data set type: - ACC: MAMA Accumulated Data - ANC: Ancillary Data - ASN: Association Data - AST: Astrometry - CAL: Calibrated SI Science Data - CDB: SI Calibration Data - CTB: SDAS Calibration and Throughput Tables - DIA: Engineering Diagnostic Data - DLG: DADS Logs - DMP: OBC Dump Data - EDT: Edited SI Science Data - ENG: Engineering Data - MSC: Mission Schedule Data - MTL: Mission Timeline Data - OCX: OSS Data Quality Comments - OMS: Observatory Monitoring System files - ORB: Ephemeris or Definitive Orbit Data - PDQ: OPUS Data Quality Comments - PRB: Problem Science Data (Data that are not validated) - SMS: Science Mission Specification Data - SUB: Engineering Subset Data - VLA: VLA Radio Survey	INPUT
ads_build_num	Build number	INTERNAL
ads_data_receipt_time	Date and time when this data set was received by the DADS system	INTERNAL
ads_data_set_name	Name of the data set.	INPUT
ads_data_set_size	Size of the data set in bytes.	INTERNAL
ads_data_source	Source from which DADS received the data set - e.g., SOGS, SDAS, USER.	INTERNAL
ads_electronic_dist_count	Number of copies of all or part of this data set which have been distributed electronically to users. (Note: This is internal distribution information for DADS.)	INTERNAL
ads_end_time	The end time of the information covered by this data set. The exact meaning is archive class dependent.	GSP.GSH.HISTORY, MTL.POD.END, MSC.POD.END, SMS.POD.END, ENG.DAT.37-48.SPACECRAFT
ads_engineering_format	Telemetry format ID (e.g., AN) (ASCII, left-justified, blank fill).	ENG.DAT.23-24.FORMAT
ads_file_count	Number of files included in the archive data set. (Note: This is internal distribution information for DADS.)	INPUT
ads_file_extension_id	File extension ID	
ads_generation_date	Date and time when the last file in this data set was generated by SOGS.	INPUT
ads_logical_vol	The logical volume of the archive volume (side A or side B) that this data set resides on. (Note: This is internal archive information for DADS.)	INTERNAL

Table B.1: The *archive_data_set_all* Table

Field	Description	Source
ads_naxis1	The number of pixels along the naxis1 for the image that can be subsetted.	AST.A*H.NAXIS1, FOC.C1H/C0H/D0H.NAXIS1, FOS.C1H/D0H.NAXIS1, HRS.C1H/D0H/D1H.NAXIS1, HSP.D0H/D2H/D1H/D3H.NAXIS1, WFPC.C0H/D0H.NAXIS1, WFPC2.C0H/D0H.NAXIS1
ads_naxis2	The number of pixels along the naxis2 for the image that can be subsetted.	FOC.C1H/C0H/D0H.NAXIS2, HRS.C1H/D0H/D1H.NAXIS2, HSP.D0H/D2H/D1H/D3H.NAXIS2, WFPC.C0H/D0H.NAXIS2, WFPC2.C0H/D0H.NAXIS2
ads_obc_dump_type	A character representing the type of data dump from the On Board Computer (OBC). It is represented by the second character of the data set file name.	DMP.filename
ads_obset_id	The Observation Set ID for the observation set to which this observation belongs.	AST.DMH.OBSET_ID, SHH.OBSET_ID
ads_obsnum	Observation number from the SOGS header.	AST.DMH.OBSERVTN, SHH.OBSERVTN
ads_od_dist_count	Number of times that all or part of this data set has been distributed to users on optical disk. (Note: This is internal distribution information for DADS.)	INTERNAL
ads_pep_id	Unique identifier assigned to the proposal by the PEP system.	SHH.PROPOSID
ads_processing_type	The level the data set was reprocessed: (NORMAL, MINOR, or MAJOR).	SHH.PROC_TYP
ads_program_id	The SOGS Program ID for the proposal which requested this observation.	AST.DMH.PROGRMID, SHH.PROGRMID
ads_release_date	Date when this data set is expected to be released from proprietary status. This date is internally calculated when proprietary data set information is stored. A data set is considered to have transitioned from proprietary to non-proprietary status if the release date is earlier than (less than or equal to) the current date. The release is considered an actual release date, if the date is less than or equal to the current date. The operator may modify this release date and set the release date to be any desired date greater than or equal to the system date and time.	INTERNAL, INPUT
ads_retrieval_requests	Number of requests from DADS users for retrieval and distribution of information from this data set. (Note: This is internal distribution information for DADS).	
ads_source_format	The formats that the data is received in. Valid values are: FITS, WFITS, SDAS and OTHER. Data sets are normally stored in FITS format. If a data set fails validation and ads_override is set on, the data set is stored in the format in which it is originally received in.	INTERNAL

Table B.1: The *archive_data_set_all* Table

Field	Description	Source
ads_special_mechanism	The date/time that the special proprietary mechanism process updated this record. A value in this column will ensure that the special proprietary mechanism process does not update this data set more than once. If the proprietary status of this data set is updated manually by the DBA as a result of the proprietary special mechanism (i.e., the special proprietary mechanism had notified the DBA that a manual change was necessary), a date/time of the update should be entered. Entering the value will ensure that the special proprietary mechanism does not continually notify the DBA that a manual update is necessary.	INTERNAL
ads_start_time	Start time of the data in this data set as follows: ENG - SPACECRAFT START TIME Corrected spacecraft (vehicle) time for the first minor frame in the file. SUB - SPACECRAFT START TIME Corrected spacecraft (vehicle) time for the first minor frame in the file. ORB - ORBIT DATE The time of the start of orbit data. GSP - HISTORY Scan start. GSD - GSP_TIME The start time of the guide star use for	SUB, SMS.POD.START, MSC.POD.START, MTL.POD.START, ENG.DAT.25-36.SPACECRAFT, ORB.ORX.datasetname.ORBIT, RTA.POD.datasetname.RTA, DMP.PKX.datasetname.MINOR, GSP.GSH.HISTORY, GSD.GSD.GSP_TIME, MVD.MVD.GSP_TIME
ads_storage_format	Internal storage format.	INTERNAL
ads_tape_dist_count	Number of times that all or part of this data set has been distributed to users on tape. (Note: This is internal distribution information for DADS.)	INTERNAL
ads_volume_id	Unique identifier for the volume. The format for volume ID is: DADSddmmyyhhmmsst where t is the volume type: s = safe store p = primary (Note: This is internal archive information for DADS.)	INTERNAL

Table B.2: The *archive_extensions* Table

Field	Contents Description	Source
aex_file_extension	The extension of the archive file.	INTERNAL
aex_file_extension_id	The extension ID of the archive file	INTERNAL

Table B.3: The *assoc_member* Table

Field	Contents Description
asm_asn_id	Unique identifier assigned to association.
asm_data_set_name	Data set name.
asm_member_name	Member name.
asm_member_type	Role of the Exposure in the Association.
asm_obset_id	The Observation Set ID for the observation set to which this observation belongs.
asm_obsnum	Observation number from the SOGS header.
asm_program_id	The SOGS Program ID for the proposal which requested this observation.

Table B.4: The *assoc_orphan* Table

Field	Contents Description
aso_asn_id	Unique identifier assigned to association.
aso_data_set_name	Data set name.
aso_member_type	Role of the Exposure in the Association.
aso_obset_id	The Observation Set ID for the observation set to which this observation belongs.
aso_obsnum	Observation number from the SOGS header.
aso_orphan_type	
aso_program_id	The SOGS Program ID for the proposal which requested this observation.

Table B.5: The *assoc_status* Table

Field	Contents Description
ast_asn_id	Unique identifier assigned to association.
ast_asn_status	The status of the association (“complete” if all of its exposures were received).
ast_generation_date	The date the association was generated.
ast_products_present	

Table B.6: The *fixed_target* Table

Field	Contents Description	Source
fit_dec_proper_motion	Declination component of target proper motion.	SHH.MU_DEC, AST.DMH.MU_DEC
fit_obset_id	The Observation Set ID for the observation set to which this observation belongs.	SHH.OBSET_ID, AST.DMH.OBSET_ID
fit_obsnum	Observation number from the SOGS header.	SHH.OBSERVTN, AST.DMH.OBSERVTN
fit_parallax	Annual parallax of the target (if provided by the proposers).	SHH.PARALLAX, AST.DMH.PARALLAX
fit_program_id	The SOGS Program ID for the proposal which requested this observation.	SHH.PROGRMID, AST.DMH.PROGRMID
fit_proper_motion	Right ascension component of the target (if provided by the proposers).	SHH.MU_RA, AST.DMH.MU_RA
fit_radial_velocity	Radial velocity of the target in km/sec (if provided by the proposers).	SHH.RAD_VEL, AST.DMH.RAD_VEL
fit_redshitf	The target redshift (if provided by the proposers).	SHH.REDSHIFT, AST.DMH.REDSHIFT
fit_type	If the target is a star, the spectral type and luminosity; if the target is a galaxy, the morphological type. (if provided by the proposers)	SHH.SP_TYPE, AST.DMH.SP_TYPE

Table B.7: The *moving_target_position* Table

Field	Contents Description	Source
mtp_level	The target position level (from 1 to 3) to which this position specification applies.	SHH.MT_LV1_*, AST.DMH.MT_LV*_*
mtp_line_number	The line number for this position specification line.	SHH.MT_LV*_*
mtp_obset_id	The Observation Set ID for the observation set to which this observation belongs.	SHH.OBSET_ID, AST.DMH.OBSET_ID
mtp_obsnum	Observation number from the SOGS header.	SHH.OBSERVTN, AST.DMH.OBSERVTN
mtp_program_id	The SOGS Program ID for the proposal which requested this observation.	SHH.PROGRMID, AST.DMH.PROGRMID
mtp_spec_text	The actual text of the target position specification line. (This text follows the standard format specified in the STScI solar system target list instructions.) The text is made up of three levels. Each level arrives from SOGS in five parts which must be reassembled by DADS before storing the information in the Catalog.	SHH.MT_LV*_*

Table B.8: The *oms_data* Table

Field	Contents Description
oms_acq2fail	Target acquisition failure.
oms_actgssep	Actual Guide Star Separation (arcsec)
oms_altitude	Average altitude during observation (km)
oms_aper_v2	V2 Aperture position in Vehicle frame (arcsec)
oms_aper_v3	V3 Aperture position in Vehicle frame (arcsec)
oms_aperture	Aperture
oms_asn_id	Unique identifier assigned to association
oms_asn_mtyp	Role of the Exposure in the Association
oms_beta_1	Angle from +V3 to image +x(toward +V2)
oms_beta_2	Angle from +V3 to image +y(toward +V2)
oms_cd1_1	Partial of first axis coordinate w.r.t. x (deg/pix)
oms_cd1_2	Partial of first axis coordinate w.r.t. y (deg/pix)
oms_cd2_1	Partial of second axis coordinate w.r.t. x (deg/pixel)
oms_cd2_2	Partial of second axis coordinate w.r.t. y (deg/pixel)
oms_clamperr	Cal lamp may not be enabled
oms_coordsys	Image coordinate system
oms_crpix1	x-coordinate of reference pixel
oms_crpix2	y-coordinate of reference pixel
oms_crval1	First axis value at reference pixel
oms_crval2	Second axis value at reference pixel
oms_ctype1	First coordinate type
oms_ctype2	Second coordinate type
oms_data_set_name	Data set name
oms_datamax	The maximum value of the data
oms_datamin	The minimum value of the data
oms_dcfunchg	DCF number unchanged from previous observation
oms_dec_avg	Average DEC (deg)
oms_endtime	Predicted Observation Window End Time
oms_expname	9 character exposure identifier
oms_extver	Extension version number

Table B.8: The *oms_data* Table

Field	Contents Description
oms_fgs_fail	FGS astrometry target acquisition failed
oms_fos_open	FOS aperture door not open
oms_fw_error	Error occurred with filter wheel
oms_gs_gap	Duration of missing tlm. during GS acquisition
oms_gsacq	Actual time of GS Acquisition Completion
oms_gsfail	Guide star acquisition failure
oms_gsseprms	RMS of Guide Star Separation (milli-arcsec)
oms_guideact	Actual Guiding mode at end of GS acquisition
oms_inherit	Inherit the primary header
oms_lockloss	Total loss of lock time (sec)
oms_los_limb	Average line of sight to Earth limb (deg)
oms_los_moon	Minimum Line Of Sight to Moon (deg)
oms_los_scv	Minimum line of sight to S/C veloc. (deg)
oms_los_sun	Minimum Line Of Sight to Sun (deg)
oms_n_tm_gap	Number of telemetry gaps during observation
oms_nlosses	Number of loss of lock events
oms_no_ephem	No JPL ephemeris available
oms_no_sam	SI requested small angle maneuver rejected
oms_no_slew	NSSC-1 executive refused to honor slew request
oms_no_tlm	No engineering telemetry available for obs.
oms_nrecent	Number of recentering events (sec)
oms_obset_id	Observation set id
oms_obsnum	Observation number (base 36)
oms_proctime	Date-Time When OMS Processed Observation
oms_program_id	Program id (base 36)
oms_proposid	PEP proposal identifier
oms_ra_avg	Average RA (deg)
oms_recentr	Total recentering time
oms_roll_avg	Average Roll (deg)
oms_sd_lost	Science data may be lost due to SI error.
oms_sgstar	Scheduled use of guide star.

Table B.8: The *oms_data* Table

Field	Contents Description
oms_shadoent	Earth shadow last entry (predicted).
oms_shadoex	Earth shadow last exit (predicted)
oms_si_safed	Science instrument safed during this observation
oms_sisuspnd	Science instrument suspended during observation
oms_slewing	Slewing occurred during this observation
oms_startime	Predicted Observation Window Start Time
oms_tapedrop	Possible loss of science data due to ETR problem
oms_tdf_down	Take-data-flag not up during entire exposure
oms_tlm_prob	Problem with the engineering telemetry
oms_tlmform	Telemetry Format
oms_tm_gap	Total duration of missing telemetry (sec.)
oms_v2_p2p	Dominant guide star V2 axis peak to peak (mas)
oms_v2_rms	Dominant guide star V2 axis RMS (mas)
oms_v3_p2p	Dominant guide star V3 axis peak to peak (mas)
oms_v3_rms	Dominant guide star V3 axis RMS (mas)
oms_xpixinc	Plate scale along X in mas per pixel
oms_ypixinc	Plate scale along Y in mas per pixel

Table B.9: The *oms_summary* Table_

Field	Contents Description
oss_acq2fail	Target acquisition failure.
oss_actgssep	Actual Guide Star Separation (arcsec)
oss_altitude	Average altitude during observation (km)
oss_aper_v2	V2 Aperture position in Vehicle frame (arcsec)
oss_aper_v3	V3 Aperture position in Vehicle frame (arcsec)
oss_aperture	Aperture
oss_asn_id	Unique identifier assigned to association

oss_xpixinc	Plate scale along X in mas per pixel
oss_ypixinc	Plate scale along Y in mas per pixel

Table B.10: The *otfc_bypass_calibration* Table

Field	Contents Description
obc_comment	Comment about this entry.
obc_data_set_name	The DADS dataset name (rootname).
obc_entry_date	The date the entry was made.
obc_inactive_date	The date on which the entry was deactivated. Only filled in for inactive states.
obc_instrument	The instrument name.
obc_pr_number	The pr number associated with this uncalibratable dataset. This number is assigned by the STScI OPR system, which contains the documentation on the problem.
obc_problem	The reason the dataset should not be calibrated. Possible values are: CORRUPTED_DATA, TOO_MUCH_TIME, SWITCH_OVERRIDE, CAL_SW_PROBLEM, OTHER
obc_state	This can be ACTIVE, INACTIVE or MISTAKE. ACTIVE refers to active entries, i.e., currently in use by OTFC, INACTIVE refers to inactive entries (no longer in use; these entries are maintained to provide a history of changes to OTFC processing). MISTAKE refers to when an operator inadvertently puts an entry in the table. When entry is set to INACTIVE or MISTAKE, obc_inactive_date is populated.
okr_user_name	User name of person requesting the change.

Table B.11: The *otfc_keyword_repair* Table

Field	Contents Description
okr_active_date	The date the keyword repair becomes ACTIVE. This happens after the corresponding DADS database field has been updated with the new value when there is a corresponding field.
okr_dads_change_date	The date this change was last applied to DADS (NULL if not yet applied). This field will be updated by the DADS Update Tools.

Table B.11: The *otfc_keyword_repair* Table

Field	Contents Description
okr_data_set_name	The DADS dataset name (rootname).
okr_entry_date	The date the repair is entered in the database in the NEW state.
okr_extname	It is the value of the EXTNAME keyword for that image extension. Used for the case of data in which changes are outside the primary header. It is used to identify the data within the imset, e.g., SCI for STIS. In the case of the primary header, it is set to a null string.
okr_extver	The value of the EXTVER keyword for that imset. In the case of the primary header, it is set to a value of zero. This is in one-to-one correspondence with the imset_value.
okr_file_extension	The file extension for the change (e.g., RAW, DOH, SPT).
okr_imset_name	Used for the case of associated data in which changes are outside the primary header. It designates the keyword name in the various headers that are used to identify the imsets in a scientifically useful way, e.g., EXPNAME for STIS, SAMPNUM for NICMOS. In the case of the primary header, it is set to PRIMARY.
okr_imset_value	Used for the case of associated data in which changes are outside the primary header. The value of the imset identifier, e.g., the value of the EXPNAME for STIS, the value of the SAMPNUM for NICMOS, and the CCD(?) for ACS. In the case of the primary header, it is set to a null string.
okr_inactive_comment	The reason why the repair was deactivated. This field is only filled in for deactivated entries.
okr_inactive_date	The date on which the repair deactivated.
okr_instrument	The instrument name.
okr_keyword	Name of keyword to be updated in headers. For best switch entries, which are not filled by keywords, this is the name of the keyword that fills the corresponding original switch field.
okr_new_keyword_value	The desired value of the keyword.
okr_old_keyword_value	The value of the keyword before the change is applied. Filled from the DADS database by the load tool.
okr_operation	What to do with the keyword. Possible values: UPDATE, INSERT, DELETE. Insert means that the keyword and new value will be added to the dataset header, if not already present. If already present, the insert will modify the keyword value to the new value. Update is the same as insert, but will not add any new keywords. Delete sets the keyword value to an empty string, but leaves the keyword in the header. It causes a value of a keyword in the DADS catalog to be set to null if the field is present.
okr_pr_number	The pr number associated with this keyword change. This number is assigned by the STScI OPR system, which contains the documentation on the problem.
okr_state	This can be NEW, ACTIVE, INACTIVE. NEW refers to new repairs that have not yet been applied to the DADS catalog, ACTIVE refers to active repairs, i.e., currently in use by OTFC, while INACTIVE refers to inactive repairs. These repairs were at one time active, but are no longer in use. These entries are maintained to provide a history of changes to OTFC processing. Such entries are useful in user support.

Table B.12: The *pdq_summary* Table

Field	Contents Description
pdq_asn_id	Unique identifier assigned to association.
pdq_comment_1	Descriptive comments about the data.
pdq_comment_2	Additional descriptive comments about the data.
pdq_comment_3	Additional descriptive comments about the data.
pdq_data_set_name	Data set name.
pdq_obset_id	The Observation Set ID for the observation set to which this observation belongs.
pdq_obsnum	Observation number from the SOGS header.
pdq_program_id	The SOGS Program ID for the proposal which requested this observation.
pdq_quality	One word summary of data quality from a standard list defined by OPUS.

Table B.13: The *proposal* Table

Field	Contents Description	Source
pro_pep_id	Unique identifier assigned to the proposal by the PEP system.	SHH.PROPOSID, AST.DMH.PROPOSID
pro_pi_first_name	The investigator's first name.	SHH.PR_INV_F, AST.DMH.PR_INV_F
pro_pi_initial	The investigator's middle initial.	SHH.PR_INV_M, AST.DMH.PR_INV_M
pro_pi_last_name	The investigator's last name.	SHH.PR_INV_L, AST.DMH.PR_INV_L
pro_program_id	The SOGS Program ID for the proposal which requested this observation.	SHH.PROGRMID, AST.DMH.PROGRMID
pro_proposal_title	The proposal title.	SHH.PROPTTL1, SHH.PROPTTL2
pro_proposal_type	The proposal type.	SHH.PROP_TYP

Table B.14: The *scan_parameters* Table

Field	Contents Description	Source
scp_angle_between_sides	The angle between the sides of the parallelogram formed by the first and last scan lines and the lines passing through the endpoints of the scan lines.	SHH.ANG_SIDE, AST.DMH.ANG_SIDE

Table B.14: The *scan_parameters* Table

Field	Contents Description	Source
scp_number_of_line	The number of scan lines.	SHH.NO_LINES, AST.DMH.NO_LINES
scp_obset_id	The Observation Set ID for the observation set to which this observation belongs.	SHH.OBSET_ID, AST.DMH.OBSET_ID
scp_obsnum	Observation number from the SOGS header.	SHH.OBSERVTN, AST.DMH.OBSERVTN
scp_points_per_line	The number of dwell points per scan line (if this is a dwell scan).	SHH.DWELL_LN, AST.DMH.DWELL_LN
scp_position_angle	Position angle of the first scan line with respect to either spacecraft or celestial coordinate system.	SHH.SCAN_ANG, AST.DMH.SCAN_ANG
scp_program_id	The SOGS Program ID for the proposal which requested this observation.	SHH.PROGRMID, AST.DMH.PROGRMID
scp_scan_coord	The frame of reference selected by the investigator for the spatial scan indicating whether the scan is to be carried out in celestial coordinates or spacecraft coordinates.	SHH.SCAN_COR, AST.DMH.SCAN_COR
scp_scan_length	The length of each scan line in arc-seconds.	SHH.SCAN_LEN, AST.DMH.SCAN_LEN
scp_scan_rate	The rate at which the spacecraft is to scan the designated part of the sky, in arc-seconds per second.	SHH.SCAN_RAT, AST.DMH.SCAN_RAT
scp_scan_type	Type of scan (e.g., Dwell or Continuous).	SHH.SCAN_TYP, AST.DMH.SCAN_TYP
scp_scan_width	The width of the specified spatial scan in arcseconds.	SHH.SCAN_WID, AST.DMH.SCAN_WID
scp_seconds_per_dwell	The number of seconds during which the spacecraft must remain stationary at each dwell point (if this is a dwell scan).	SHH.DWELL_TM, AST.DMH.DWELL_TM

Table B.15: The *science* Table

Field	Contents Description	Source
sci_actual_duration	The actual duration of the exposure in seconds.	data header keywords
sci_aper_1234	Concatenated identifier for the 1-4 aperture elements used in the given optical configuration.	data header keywords

Table B.15: The *science* Table

Field	Contents Description	Source
sci_archive_class	The archive class for this data set type: - ACC: MAMA Accumulated Data - ANC: Ancillary Data - ASN: Association Data - AST: Astrometry - CAL: Calibrated SI Science Data - CDB: SI Calibration Data - CTB: SDAS Calibration and Throughput Tables - DIA: Engineering Diagnostic Data - DLG: DADS Logs - DMP: OBC Dump Data - EDT: Edited SI Science Data - ENG: Engineering Data - MSC: Mission Schedule Data - MTL: Mission Timeline Data - OCX: OSS Data Quality Comments - OMS: Observatory Monitoring System files - ORB: Ephemeris or Definitive Orbit Data - PDQ: OPUS Data Quality Comments - PRB: Problem Science Data (Data that are not validated) - SMS: Science Mission Specification Data - SUB: Engineering Subset Data - VLA: VLA Radio Survey.	data header keywords
sci_asn_id	Unique identifier assigned to association.	data header keywords
sci_bandwidth	Bandwidth of the data (STIS) or RMS bandwidth of the photmode (NICMOS).	data header keywords
sci_broad_category	The broad category to which the target for a given observation belongs, e.g., Star, Galaxy, Quasar, Planet.	data header keywords
sci_central_wavelength	Central wavelength of the data (STIS) or pivot wavelength of the photmode (NICMOS).	data header keywords
sci_costar_deploy	Was COSTAR deployed at the time the dataset was obtained? (i.e. after the servicing mission) (T/F).	data header keywords
sci_data_set_name	The name of the data set.	data header keywords
sci_dec	The declination value for this location, in decimal degrees.	data header keywords
sci_dec_v1	The 0.0 declination of v1 axis of ST (deg).	data header keywords
sci_dispersion	The dispersion for an HST spectrographic observation.	data header keywords
sci_ecliptic_latitude	The ecliptic latitude value for this location, in decimal degrees.	data header keywords
sci_ecliptic_longitude	The ecliptic longitude value for this location, in decimal degrees.	data header keywords
sci_expflag	The exposure interruption indicator.	data header keywords
sci_fgslock	The commanded FGS lock (FINE, COARSE, GYROS, UNKOWN).	data header keywords
sci_fov_config	Field of view configuration.	data header keywords
sci_galactic_latitude	The galactic latitude value for this location, in decimal degrees.	data header keywords
sci_galactic_longitude	The galactic longitude value for this location, in decimal degrees.	data header keywords
sci_generation_date	The date the exposure was generated.	data header keywords
sci_instrume	Instrument in use.	data header keywords

Table B.15: The *science* Table

Field	Contents Description	Source
sci_instrument_config	Name of the instrument configuration for this optical configuration, e.g.: - FOC/288 (F/288 FOC configuration) - FOS/RD (Red-range FOS detector).	data header keywords
sci_mtflag	The moving target flag; T if it is a moving target.	data header keywords
sci_obset_id	The Observation Set ID for the observation set to which the observation belongs.	data header keywords
sci_obsnum	Observation number from the SOGS header.	data header keywords
sci_operating_mode	The HST instrument data mode used to make the exposure.	data header keywords
sci_pa_aper	Position angle of aperture used with target.	data header keywords
sci_pep_id	The PEP Proposal ID for the proposal which includes this exposure.	data header keywords
sci_pi_last_name	The principal investigator's last name.	data header keywords
sci_pixel_res	Plate scale (arcsec/pixel).	data header keywords
sci_pep_expnum	The Exposure ID assigned by PEP to the exposure to which this observation corresponds.	data header keywords
sci_program_id	The SOGS Program ID for the proposal that requested the data.	data header keywords
sci_ra	The Right Ascension value for this location, in decimal degrees.	data header keywords
sci_ra_v1	The 0.0 right ascension of v1 axis of ST (deg).	data header keywords
sci_release_date	Date when this data set is expected to be released from proprietary status. This date is internally calculated when proprietary data set information is stored. A data set is considered to have transitioned from proprietary to non-proprietary status if the release date is earlier than (less than or equal to) the current date. The release is considered an actual release date, if the date is less than or equal to the current date. The operator may modify this release date and set the release date to be any desired date greater than or equal to the system date and time.	data header keywords
sci_spec_1234	Concatenated identifier for the 1-4 spectral elements used in the given optical configuration.	data header keywords
sci_spectral_res	Spectral resolution for this optical configuration (for spectra).	data header keywords
sci_spectrum_end	Maximum wavelength for this HST spectrum.	data header keywords
sci_spectrum_start	Minimum wavelength for this HST spectrum.	data header keywords
sci_start_time	Exposure start time (Modified Julian Date) or start time of 1st exposure in file (STIS).	data header keywords
sci_stop_time	Exposure end time (Modified Julian Date) or start time of last exposure in file (STIS).	data header keywords
sci_sun_alt	Altitude of the sun above Earth's limb (deg).	data header keywords

Table B.15: The *science* Table

Field	Contents Description	Source
sci_targname	Common name of the target.	data header keywords
sci_target_descrip	Descriptive information about the target of this observation. This information is received in two parts. DADS concatenates them so that the description is stored in the Catalog as one value.	data header keywords
sci_v3_pos_angle	V3 position angle.	data header keywords

Table B.16: The *shp_data* Table

Field	Contents Description	Source
shp_accpdate	The proposal acceptance date (YD= yyyyddd).	SHH.ACCPDATE, AST.DMH.ACCPDATE
shp_anglesep	The angle separation of target from reference object (arcsecond).	SHH.ANGLESEP, AST.DMH.ANGLESEP
shp_annparra	The parallax shift in position, non- solar system target.	SHH.ANNPARRA, AST.DMH.ANNPARRA
shp_aperobj	The SI object aperture id.	SHH.APEROBJ, AST.DMH.APEROBJ
shp_aperoffx	The x component of object offset in aperture (arcsec).	SHH.APEROFFX, AST.DMH.APEROFFX
shp_aperoffy	The y component of object offset in aperture (arcsec).	SHH.APEROFFY, AST.DMH.APEROFFY
shp_apersky	The SI sky aperture id.	SHH.APERSKY, AST.DMH.APERSKY
shp_apertype	The aperture type (SICS, SIAS, SIDS).	SHH.APERTYPE AST.DMH.APERTYPE
shp_archive_class	The archive class of the data associated with this data set.	INPUT
shp_argperig	The argument of perigee (revolutions/ second).	SHH.ARGPERIG, AST.DMH.ARGPERIG
shp_asn_id	Unique identifier assigned to association.	
shp_cal_ver	CALSTIS (STIS) or CALNIC (NICMOS) code version.	
shp_calibrat	The Calibrate data flag.	SHH.CALIBRAT, AST.DMH.CALIBRAT
shp_calibtyp	The calibration type: E, I, or Blank.	SHH.CALIBTYP, AST.DMH.CALIBTYP
shp_cdbsdata	The CDBS notification flag.	SHH.CDBSDATA, AST.DMH.CDBSDATA
shp_cirveloc	The circular orbit linear velocity (meters/seconds).	SHH.CIRVELOC, AST.DMH.CIRVELOC
shp_clkdrftr	The spacecraft clock drift rate.	SHH.CLKDRFTR
shp_clkrate	The spacecraft clock rate.	SHH.CLKRATE

Table B.16: The *shp_data* Table

Field	Contents Description	Source
shp_cmd_exp	Commanded time per exposure (from TRANS).	
shp_col_b_v	Expected B-V color.	
shp_col_u_b	Expected U-B color.	
shp_col_v_r	Expected V-R color.	
shp_cosincli	The cosine of inclination.	SHH.COSINCLI, AST.DMH.COSINCLI
shp_data_set_name	The name of the data set.	INPUT
shp_dcfobsn	The Data Capture Facility (DCF) observation number in the SHP.	SHH.DCFOBSN
shp_dec_moon	The declination of the moon (deg).	SHH.DEC_MOON, AST.DMH.DEC_MOON
shp_dec_ref	The declination of reference object (deg).	SHH.DEC_REF, AST.DMH.DEC_REF
shp_dec_sun	The declination of the sun (deg).	SHH.DEC_SUN, AST.DMH.DEC_SUN
shp_dec_targ	The declination of the target (deg).	SHH.DEC_TARG, AST.DMH.DEC_TARG
shp_dec_v1	The 0.0 declination of v1 axis of ST (deg).	SHH.DEC_V1, AST.DMH.DEC_V1
shp_dgestar	The Fine Guidance Sensor (FGS) ID (F1, F2, F3) concatenated with dominate guide star id.	SHH.DGESTAR, AST.DMH.DGESTAR
shp_e_b_v	E(B-V).	
shp_ecbdx3	The eccentricity cubed times 3.	SHH.ECBDX3, AST.DMH.ECBDX3
shp_ecbdx4d3	The eccentricity cubed times 4/3.	SHH.ECBDX4D3, AST.DMH.ECBDX4D3
shp_eccentry	The eccentricity.	SHH.ECCENTRY, AST.DMH.ECCENTRY
shp_eccentx2	The eccentricity times 2.	SHH.ECCENTX2, AST.DMH.ECCENTX2
shp_epchtime	The epoch time of parameters (ES= Elapsed seconds since 1/1/85).	SHH.EPCHTIME, AST.DMH.EPCHTIME
shp_eplongpm	The epoch of longitude of prime meridian (sec).	SHH.EPLONGPM, AST.DMH.EPLONGPM
shp_eqradtrg	The equatorial radius of target (km).	SHH.EQRADTRG, AST.DMH.EQRADTRG
shp_esqdx5d2	The eccentricity squared times 5/2.	SHH.ESQDX5D2, AST.DMH.ESQDX5D2
shp_expacket	The expected number of source packets.	SHH.EXPACKET, AST.DMH.EXPACKET
shp_extnct_v	Extinction in V.	

Table B.16: The *shp_data* Table

Field	Contents Description	Source
shp_fdmeanan	The 1st derivative coefficient for mean anomaly (revs/sec).	SHH.FDMEANAN, AST.DMH.FDMEANAN
shp_flatntrg	The flattening of target.	SHH.FLATNTRG, AST.DMH.FLATNTRG
shp_fltswver	Flight software version number.	
shp_hsthorb	Half the duration of the ST orbit (seconds).	SHH.HSTHORB, AST.DMH.HSTHORB
shp_instrume	The instrument used in the observation. Valid values are: FGS, FOC, FOS, HRS, HSP, WFPC. NOTE: NULL values are not allowed.	SHH.INSTRUME, AST.DMH.INSTRUME, WFPC2.C0H/D0H.INSTRUME
shp_linenum	Proposal logsheet line number.	
shp_longpmer	The longitude of prime meridian (deg).	SHH.LONGPMER, AST.DMH.LONGPMER
shp_mag_b	Expected B Magnitude.	
shp_mag_r	Expected R Magnitude.	
shp_mag_u	Expected U Magnitude.	
shp_mag_v	Expected V Magnitude.	
shp_meananom	The mean anomaly (radians).	SHH.MEANANOM, AST.DMH.MEANANOM
shp_mu_epoch	Epoch of proper motion from proposal.	
shp_obset_id	The Observation Set Id for the observation set to which this observation belongs.	SHH.OBSET_ID, AST.DMH.OBSET_ID
shp_obsnum	Observation number (base 36) from the SOGS header.	SHH.OBSNUM, AST.DMH.OBSNUM
shp_obsstrtt	The predicted observation start time (ES= Elapsed seconds since 1/1/85).	SHH.OBSSTRTT, AST.DMH.OBSSTRTT
shp_opformat	The output product format specification.	SHH.OPFORMAT, AST.DMH.OPFORMAT
shp_opus_ver	OPUS software system version number.	
shp_pa_ref	The position angle of target from reference object (degrees).	SHH.PA_REF, AST.DMH.PA_REF
shp_par_corr	The parallax correction used (T or F).	SHH.PAR_CORR, AST.DMH.PAR_CORR
shp_parentid	PEP proposal identifier of the parent proposal	
shp_pep_expo	The Exposure Id assigned by PEP to the exposure to which this observation corresponds.	SHH.PEP_EXPO, AST.DMH.PEP_EXPO
shp_postnstx	The position of space telescope x axis (km).	SHH.POSTNSTX, AST.DMH.POSTNSTX
shp_postnsty	The position of space telescope y axis (km).	SHH.POSTNSTY, AST.DMH.POSTNSTY
shp_postnstz	The position of space telescope z axis (km).	SHH.POSTNSTZ, AST.DMH.POSTNSTZ

Table B.16: The *shp_data* Table

Field	Contents Description	Source
shp_prodtype	The output product medium type.	SHH.PRODTYPE, AST.DMH.PRODTYPE
shp_program_id	The SOGS program id (base 36) for the proposal which requested this observation.	SHH.PROGRMID, AST.DMH.PROGRMID
shp_proposid	The PEP Proposal Id for the proposal that requested this observation.	SHH.PROPOSID, AST.DMH.PROPOSID
shp_pstptime	The predicted observation stop time (J= Julian format).	SHH.PSTPTIME, AST.DMH.PSTPTIME
shp_pstrtime	The predicted observation start time (J= Julian format).	SHH.PSTRTIME, AST.DMH.PSTRTIME
shp_ra_moon	The right ascension of the moon (deg).	SHH.RA_MOON, AST.DMH.RA_MOON
shp_ra_ref	The right ascension of reference object (deg).	SHH.RA_REF, AST.DMH.RA_REF
shp_ra_sun	The right ascension of the sun (deg).	SHH.RA_SUN, AST.DMH.RA_SUN
shp_ra_targ	The right ascension of the target (deg).	SHH.RA_TARG, AST.DMH.RA_TARG
shp_ra_v1	The 0.0 right ascension of v1 axis of ST (deg).	SHH.RA_V1, AST.DMH.RA_V1
shp_rascascn	The right ascension of ascending node (revolutions).	SHH.RASCASCN, AST.DMH.RASCASCN
shp_rcargper	The rate change of argument of perigee (revs/sec).	SHH.RCARGPER, AST.DMH.RCARGPER
shp_rcascnrd	The rate change right ascension ascend node (rads/sec).	SHH.RCASCNRD, AST.DMH.RCASCNRD
shp_rcascnrv	The rate change right ascension ascend node (revs/sec).	SHH.RCASCNRV, AST.DMH.RCASCNRV
shp_rotrttrg	The rotation rate of target.	SHH.ROTRTTRG, AST.DMH.ROTRTTRG
shp_rtamatch	The above f&i match RTA (TRUE, FALSE, NO RTA F&I AVL).	SHH.RTAMATCH
shp_saaavoid	The SAA model for SAA Avoidance (range 02-99).	SHH.SAAAVOID, AST.DMH.SAAAVOID
shp_sdma3sq	The calculation: 3*(shp_mean_anomaly_coef_2**2) radians/second**2.	SHH.SDMA3SQ, AST.DMH.SDMA3SQ
shp_sdmeanan	The 2nd derivative coefficient for mean anomaly (revs/sec/sec).	SHH.SDMEANAN, AST.DMH.SDMEANAN
shp_semilrec	The semi-latus rectum (meters).	SHH.SEMILREC, AST.DMH.SEMILREC
shp_seqline	PEP line number of defined sequence.	
shp_seqname	PEP define/use sequence name.	
shp_sgestar	The FGS ID (F1, F2, F3) concatenated with subdominate guide star id.	SHH.SGESTAR, AST.DMH.SGESTAR

Table B.16: The *shp_data* Table

Field	Contents Description	Source
shp_sineincl	The sine of inclination.	SHH.SINEINCL, AST.DMH.SINEINCL
shp_spclincn	The spacecraft clock at Coordinated Universal Time (UtCO).	SHH.SPCLINCN
shp_surf_b	Expected B surface brightness.	
shp_surf_r	Expected R surface brightness.	
shp_surf_u	Expected U surface brightness.	
shp_surf_v	Expected V surface brightness.	
shp_t51_angl	The position angle of motion of aperture (deg).	SHH.T51_ANGL, AST.DMH.T51_ANGL
shp_t51_rate	The rate of motion commanded (arcsecs/ sec).	SHH.T51_RATE, AST.DMH.T51_RATE
shp_tar_type	Target type.	
shp_taraqmod	The target acquisition mode (values 00, 01, 02, 03).	SHH.TARAQMOD, AST.DMH.TARAQMOD
shp_targ_id	SPSS target ID from proposal+target number.	
shp_targdist	The distance to target from Earth center (km).	SHH.TARGDIST, AST.DMH.TARGDIST
shp_timeffec	The time parameters took effect (ES= seconds since 1/1/85).	SHH.TIMEFFEC, AST.DMH.TIMEFFEC
shp_trk_type	The track 48 or track 51 commanding used (T48, T51).	SHH.TRK_TYPE, AST.DMH.TRK_TYPE
shp_utc0	Coordinated Universal Time (MJ= Modified Julian Date format).	SHH.UTC0
shp_utco1	Bytes 5-8 of the Coordinated Universal Time (UTC0) (MJD).	SHH.UTCO1
shp_utco2	Bytes 1-4 of the Coordinated Universal Time (UTC0) (MJD).	SHH.UTCO2
shp_v2aperce	The V2 offset of target from aperture center (arcsec).	SHH.V2APERCE, AST.DMH.V2APERCE
shp_v3aperce	The V3 offset of target from aperture center (arcsec).	SHH.V3APERCE, AST.DMH.V3APERCE
shp_velabbra	The aberration in position of the target.	SHH.VELABBRA, AST.DMH.VELABBRA
shp_velocstx	The velocity of space telescope along x axis (km/sec).	SHH.VELOCSTX, AST.DMH.VELOCSTX
shp_velocsty	The velocity of space telescope along y axis (km/sec).	SHH.VELOCSTY, AST.DMH.VELOCSTY
shp_velocstz	The velocity of space telescope along z axis (km/sec).	SHH.VELOCSTZ, AST.DMH.VELOCSTZ
shp_wrd11_14	Numerical identifier used to group packets together to form an observation (The word 11/14 (0-225)).	SHH.WRD11_14, AST.DMH.WRD11_14

Table B.17: The *sms_data* Table

Field	Contents Description	Source
sms_archive_class	The archive class for the Science Mission.	INPUT
sms_calendar	The SPSS calendar identifier.	SMS.POD.CALENDAR
sms_data_set_name	The name of the data set.	INPUT
sms_generation_date	Date and time when the last file in this dataset was generated by SOGS.	INPUT
sms_data sms_pdb_id	A mnemonic identifier for the ST project database.	SMS.POD.PDB_ID

Table B.18: The *target_keyword* Table

Field	Contents Description	Source
tak_broad_category	The broad category to which the target for a given observation belongs, e.g.: - Star - Galaxy - Quasar - Planet.	AST.DMH.TARGCAT, SHH.TARGCAT, SHH.TARGCAT2, AST.DMH.TARGCAT2
tak_keyword_text	The actual keyword(s). Up to ten (10) different keywords may exist for each target.	DBA, SHH.TARKEY1, through SHH.TARKEY10, AST.DMH.TARKEY1 through AST.DMH.TARKEY10
tak_obset_id	The Observation Set ID for the observation set to which this observation belongs.	SHH.OBSET_ID, AST.DMH.OBSET_ID
tak_obsnum	Observation number from the SOGS header.	SHH.OBSERVTN, AST.DMH.OBSERVTN
tak_program_id	The SOGS Program ID for the proposal which requested this observation.	SHH.PROGRMID, AST.DMH.PROGRMID

Table B.19: The *target_synonym* Table

Field	Contents Description	Source
tsy_name	The text of the target synonym.	AST.DMH.ALIAS1, AST.DMH.ALIAS2,SHH.ALIAS2, SHH.ALIAS1, SHH.TARGNAME1, AST.DMH.TARGNAME, FOC.C1H/C0H/D0H.TARGNAME, FOS.C1H/D0H.TARGNAME, HRS.C1H/D0H/D1H.TARGNAM HSP.D0H/D2H/D1H/D3H.TARGN AME, WFPC.C0H/D0H.TARGNAME, WFPC2.C0H/D0H.TARGNAME
tsy_obset_id	The Observation Set ID for the observation set to which this observation belongs.	SHH.OBSET_ID, AST.DMH.OBSET_ID
tsy_obsnum	Observation number from the SOGS header.	SHH.OBSERVTN, AST.DMH.OBSERVTN
tsy_program_id	The SOGS Program ID for the proposal which requested this observation.	SHH.PROGRMID, AST.DMH.PROGRMID

Calibration Database

The Calibration Database (CDBS) contains information on the raw data used to create the recommended reference files. While you can access the entire CDBS from the <Custom Query> screen, formatted StarView screens only use some of the tables in this database. Users interested in obtaining more information should consult the CDBS WWW page at `http://www.stsci.edu/instruments/observatory/cdbs/cdbs.html`. Tables in the CDBS are organized as follows: each instrument has an associated _file and _row level table. The _file level tables contain a description of the calibration file as a whole, while the _row level tables contain a description of the contents of the calibration file. In the case of calibration tables the _row files describe the important information of the individual rows of the calibration table. Tables in the CDBS are:

- **foc_file**
- **foc_row**
- **fos_file**
- **fos_row**
- **hrs_file**
- **hrs_row**
- **hsp_file**
- **hsp_row**
- **nic_file**
- **nic_row**
- **stis_file**
- **stis_row**
- **synphot_file**
- **synphot_row**
- **wfpc2_file**
- **wfpc2_row**
- **wfpc_file**
- **wfpc_row**

Proposal Database

The tables in the Proposal database allow users to examine information provided by observers in their Phase II proposals. This includes administrative information such as the proposers' names and addresses, scientific justification provided in the abstract, and detailed scheduling information such as target positions, exposure times, and filters and gratings selected. We give here a detailed description of the **conflicts** table only. Tables and views (or virtual tables) in the Proposal database include:

- **abstract**: This table contains the summary description of the proposed observation strategy for all approved HST programs.
- **address_view**: This view contains both physical and e-mail address information for PIs and COIs and is associated with their respective proposal ids. It is a view of the address and investigator tables in the ASSIST database.
- **conflicts**: This table contains exposure level information on completed, planned, and GTO protected targets. Information in the table is used by prospective HST observers for duplication checking prior to phase I proposal submissions. Page 256.
- **conflicts_abstract**: This table contains summary description of proposed observation strategy information on completed, planned and GTO protected.
- **coverpage**: This table contains proposal level information for all approved HST programs including title, scientific category and proposal type (i.e., GO, GTO/STIS, CAL/WF2, etc.).
- **exposure**: This table contains phase II exposure level information related to the structure of exposures for all approved HST programs.
- **proposals**: Information in the table is used by prospective HST observers for duplication checking prior to phase I proposal submissions.
- **prop_track:** This table contains proposal level information for tracking the processing status/progress of approved HST programs from PI submission to flight ready to completion.
- **su_track**: This table contains visit level information for tracking the processing status/progress of visits from submission to flight ready to completion.
- **tar_fixedpos_j2000**: This table contains information on the right ascension and declination of fixed targets (fixed, generic and solar system) of all approved HST programs.
- **targets:** This table contains target description information on all fixed targets (fixed, generic and solar system) of approved HST programs.

Table B.20: The *conflicts* Table

Field	Contents Description
con_actual_duration	Actual exposure time (seconds).
con_aper_1234	Instrument aperture.
con_central_wavelength	Central wavelength.
con_conflict_type	Type of conflict.
con_data_set_name	Data set name.
con_dec	Declination of target as given in proposal (deg) (J2000)
con_exp_num	Exposure number.
con_exp_status	Exposure status.
con_instrume	Instrument used for observation.
con_instrument_config	Configuration of instrument.
con_number_of_exposures	Number of exposures.
con_number_of_visits	Number of visits.
con_operating_mode	Operation mode.
con_pdq_comment_1	PODPS Data Quality comment one.
con_pdq_comment_2	PODPS Data Quality comment two.
con_pdq_comment_3	PODPS Data Quality comment three.
con_pep_id	Proposal Identification number in PEPSI database.
con_pi_last_name	Principal Investigator last name.
con_prop_type	Proposal type. Examples: GO, GTO, SNAP, GTO/WF2, GTO/NIC, CAL/FOC, ...
con_proposal_cycle	Proposal cycle.
con_ra	Right ascension of target as given in proposal (deg) (J2000).
con_release_date	Release date.
con_sci_category	Scientific category.
con_spec_1234	Spectral elements.
con_start_time	Start time of exposure.
con_target_descrip	Target description.
con_targname	Proposer supplied target name.
con_visit_id	Visit ID.

HST Data Handbook

February 2002

The HST Data Handbook describes datasets produced by each instrument aboard the Hubble Space Telescope. Techniques for reading, displaying, understanding, calibrating, and analyzing datasets are presented for all data sent to observers or available through the HST Data Archive.

Introduction	A general look at file formats, tools and methods for reducing and analyzing HST data PDF version (1.29 Mb) [Introductory and appendix material common to all Instruments]
ACS	Advanced Camera for Surveys PDF version (1.55 Mb) [instrument only]
FGS	Fine Guidance Sensors PDF version (1.48 Mb) [instrument only]
NICMOS	Near Infrared Camera and Multi Object Spectrometer PDF version (3.13 Mb) [instrument only]
STIS	Space Telescope Imaging Spectrograph PDF version (1.47 Mb) [instrument only]
WFPC2	Wide Field Planetary Camera 2 PDF version (2.07 Mb) [instrument only]
Appendix	References to IRAF, file naming, & observation logs. PDF version (1.29 Mb) [Introductory and appendix material common to all Instruments]

Volume 2: Heritage Instruments

March 1998

This volume focuses on the instruments that are no longer onboard the spacecraft-the heritage instruments. These instruments are: FOS, GHRS, HSP, and WF/PC-1.

Preface	How to use this Handbook PDF version (123 Kb)
FOS	Faint Object Spectrograph PDF version (1.9 Mb)
GHRS	Goddard High Resolution Spectrograph PDF version (1.7 Mb)
HSP	High Speed Photometer PDF version (178 Kb)
WFPC1	Wide Field Planetary Camera 1 PDF version (798 Kb)
Appendices	internet resources, task examples, and index PDF version (381 Kb)

* StarView Version 3.8 Installed
* Distributed StarView Export Restriction Lifted
* New Archive Manual Available Soon
* VLA FIRST Survey Archived at STScI
* New Archive WWW Pages

StarView Version 3.8 Installed

We are pleased to announce the installation of StarView Version 3.8.

Several bug fixes are incorporated into this new version, as well as several new features:

* An improved table-format screen for search results, which lets you delete and resize columns. The table also has a smoother vertical scroll.

* A screen for the newly archived VLA FIRST Survey.

* A facility for using custom-designed search screens.

StarView 3.8 will be installed this morning (Tuesday, Jan 17) on STScI's internal computers, and on the Archive Host machines, stdata.stsci.edu and stdatu.stsci.edu.

Distributed StarView 3.8 will be available by Wednesday, Jan 18. You may download the software via FTP from stdatu.stsci.edu (username: starftp, password: your email address), or through the HST Archive's World Wide Web Server (http://stdatu.stsci.edu/dist_starview.html; be sure to set the "load to local disk" option on your browser before downloading.)

One change you may need to make in your environment.dat file, if you have one, is to append "other_sci_data" to the "catalogDDLList" and "initialAdHocDBs" lines. (environment.dat is a file created by StarView when you save any changes you've made through the "Options" menu. The file resides in a subdirectory of your directory called .svdata in Unix, [.SVDATA] in VMS.) The lines should then read:

```
catalogDDLList:         catalog,proposaldb,cdb1,other_sci_data
...
initialAdHocDBs:                catalog,proposaldb,cdb1,other_sci_data
```

For more information, contact the HST Archive Hotseat.

Distributed StarView Export Restriction Lifted

Formerly, exportation of Distributed StarView was limited because of some encryption software it contains. (Distributed StarView is a version of the X-StarView software that users may run on their own machines; see http://stdatu.stsci.edu/dist_starview.html.) However, this export restriction has been lifted for Distributed StarView, and the software is now available to users outside the US and Canada.

Please be sure to register when downloading the Distributed StarView software. While registration is optional, it will allow us to keep you informed of new releases of StarView.

New Archive Manual Available Soon

Version 5.0 of the Archive Manual will be available January 20. It is fully updated for DADS, including a complete description of the DADS database. The Archive Primer has not been updated, and will still serve as an general guide for StarView users; the Manual describes higher-level functions of StarView for the advanced user, and includes a description of the DADS database.

You may request printed copies of the Archive Manual by contacting the Archive Hotseat at the address below, or see http://stdatu.stsci.edu/documents.html for more information.

VLA FIRST Survey Archived at STScI

The first 1039 coadded images from the VLA FIRST Survey's 1993 observations have been imported into the HST Archive. A description of the survey is available at http://sundog.stsci.edu/.

The files are available for retrieval through StarView. StarView Version 3.8 has a VLA screen especially for the Survey, in which you can search for files covering specified areas of the sky, and mark them for retrieval. When retrieving, override the standard file options and specify 'VLA' for the archive class.

For more information about accessing the files, see http://stdatu.stsci.edu/first_data.html, or contact the Archive Hotseat.

New Archive WWW Pages

The HST Archive has a new set of World-Wide Web pages:

    http://www.stsci.edu/archive.html

If you have any questions or comments about StarView or the HST Archive, contact the Archive Hotseat:

Internet: archive@stsci.edu
SPAN: STSCIC::ARCHIVE or 6559::ARCHIVE
Phone: (410) 338-4547.

Archive, SCARS Division

----

* StarView Version 3.9 Installed
* Archive Manual 5.1 Available

StarView Version 3.9 Installed

We are pleased to announce the installation of StarView Version 3.9.

This new version fixes some bugs, and features a separate button for selecting OMS files for retrieval.

StarView 3.9 will be installed this morning (Tuesday, Mar 21) on STScI's internal computers, and on the Archive Host machines, stdata.stsci.edu and stdatu.stsci.edu. Along with the StarView installation, the DADS Archive software is being upgraded, too (the Archive will be out of service all day for the installation). As part of the upgrade, the per-request limit on the number of datasets has been tripled.

Distributed StarView 3.9 will be available by Wednesday, Mar 22. You may download the software via FTP from stdatu.stsci.edu (username: starftp, password: your email address), or through the HST Archive's World Wide Web Server (http://stdatu.stsci.edu/dist_starview.html; be sure to set the "load to local disk" option on your browser before downloading.)

For more information, contact the HST Archive Hotseat.

Archive Manual 5.1 Available

Version 5.1 of the Archive Manual is now available. It fixes some documentation bugs, like tables that were left out of the Database Description in Appendix D.

You may request printed copies of the Archive Manual by contacting the Archive Hotseat at the address below, or see http://stdatu.stsci.edu/documents.html for more information.

If you have any questions or comments about StarView or the HST Archive, contact the Archive Hotseat:

Internet: archive@stsci.edu
SPAN: STSCIC::ARCHIVE or 6559::ARCHIVE
Phone: (410) 338-4547.

```

May 23, 1995   Space Telescope Science Institute   Volume   3

* StarView Version 4.0 Installed
* WWW Access to the Digitized Sky Survey

StarView Version 4.0 Installed

We are pleased to announce the installation of StarView Version 4.0.

StarView 4.0 features:

* A screen for extracting scans from the complete Digitized Sky Survey CD-ROMS (disks 1-102).
* A new version of SAOimage that displays world coordinates in the preview images.
* Output from a screen may be written to a file to be used as cross-correlation input in another screen.

Users of Distributed StarView will notice that the package is a little smaller now. That's because StarView now fetches the screen definitions and help files from STScI via http. This will help us keep the screen files updated and corrected here, without requiring you to install them at your site.

You may download the software via FTP from stdatu.stsci.edu (username: starftp, password: your email address), or through the HST Archive's World Wide Web Server (http://stdatu.stsci.edu/dist_starview.html; be sure to set the "load to local disk" option on your browser before downloading.)

WWW Access to the Digitized Sky Survey

In addition to accessing the Digitized Sky Survey CD-ROMs through StarView (see above), you can now access them through the World Wide Web. Point your browser to

http://stdatu.stsci.edu/dss/dss_form.html

You can enter either an RA & Dec, or you can use this form's target name resolver to get the RA/Dec for you, either from SIMBAD or NED. Scans of up to 60 x 60 arcminutes may be retrieved, with a default of 15 x 15. (This default scan yields a FITS file of about a little over 500 kilobytes.)

Image formats available are: FITS (uncompressed, gzip compressed, or Unix compressed), FITS with a generic mime type (to make your browser save the file to disk instead of trying to display it), and GIF.

If you have any questions or comments about StarView or the HST Archive, contact the Archive Hotseat:

Internet: archive@stsci.edu
SPAN: STSCIC::ARCHIVE or 6559::ARCHIVE
Phone: (410) 338-4547.

* HST ARCHIVE USER SURVEY

* STARVIEW 4.2

* NEW FEATURES OF DADS
  + Retrieve Data Directly To Your Home Site.
  + PIs May Retrieve Their Own Data.

* THE HUBBLE DEEP FIELD: AVAILABILTY OF REDUCED DATA

* WWW ACCESS TO THE 2ND-GENERATION DIGITIZED SKY SURVEY

* UPGRADE OF STDATU TO SOLARIS 2.4

-=-

HST ARCHIVE USER SURVEY

From now trough January 1996, we're conducting a survey through the World Wide Web of our archive users. We'd like to hear your suggestions and comments on recalibration, GO/GTO data media, and Archive services. The survey is located at

http://stdatu.stsci.edu/survey/

and will be running from now until January 31, 1996. If you do not have access to the World Wide Web but would like to participate in the survey, contact the Archive Hotseat for an ASCII version of the survey form.

-=-

STARVIEW 4.2

The new version of StarView, version 4.2, includes some new features.

+ New Table Export Editing Features

When saving the results of a StarView search into a file, you can now customize the file's width and column order. Simply hit the "View Results as Table" button to bring up the results of your search in table format, and customize the table format: Use the third mouse button on a column to delete or resize the width of a column, or use the second mouse button on a column name to drag-and-drop that column to another place in the table. When you save the table to a file, the customizations you make will be applied.

+ Overlay the HST Field of View onto DSS Scans

StarView now allows you not only to access the Digitized Sky Survey, but to overlay the HST field of view on it as well. In the DSS screen, specify the RA and Dec of the center of the FOV, and a roll angle (counterclockwise degrees). StarView will fetch a scan from the DSS, compute the FOV, and display the field in SAOimage with the field of view displayed on the field.

In addition, each search screen now has an "Overlay" button. After finding a dataset, simply press the "Overlay" button, and StarView will fetch and display that area of the sky from the DSS with the FOV overlaid onto the field.

+ The New Observatory Monitoring (OMS) screen.

This screen facilitates the retrieval of OMS jitter files and includes the ability to search under many new and previously unavailable fields, including:

- o The average telescope roll angle at time of observation.
- o The angles between the line of sight and the Earth and Sun limbs.
- o The jitter amplitude limits.

The Search Results screen also includes information about the line of sight to the Moon. The OMS Search screen can be found on the Other Searches screen.

+ Distributed StarView Platforms

Distributed StarView is now available for the following platforms

- o SunOS 4.1.3
- o Solaris 2.4
- o Digital UNIX on Alpha (DEC OSF/1)
- o OpenVMS VAX V6.1
- o OpenVMS Alpha V6.1 *** new! ***

Distributed StarView is available via anonymous FTP at stdatu.stsci.edu, in the directory pub/starview, or via the World Wide Web at http://stdatu.stsci.edu/dist_starview.html.

-=-

NEW FEATURES OF DADS

We have installed the next release of the software for DADS, the Space Telescope Data Archiving and Distribution System. Here are some of the new features that are part of this new release:

+ Retrieve Data Directly To Your Home Site

External users may now retrieve data directly to their home site, instead of retrieving to an archive host staging disk.

Guest users on stdata.stsci.edu and stdatu.stsci.edu, and users of Distributed StarView, will need to set an environment variable before running StarView to enable this feature; for Unix versions, do

```
% setenv SV_NETDIST_OK YES
```

and on OpenVMS, do

```
$ DEFINE SV_NETDIST_OK YES
```

Then start up StarView. While building a retrieval request, the Media Options screen (where you give your archive username and password) will contain some new fields for the destination and directory, and for your username and password on that node. Simply specify in these fields the nodename and directory of the machine to which you'd like your data delivered, and your account name and password on that machine.

The destination information will be encrypted before it is sent to the Archive, and remains encrypted while your request is being processed. However, if you wish to augment this security, and if you have access to an incoming directory on an anonymous FTP server, you can use this feature to have the data sent there. Alternatively, you can still retrieve to the Archive host staging disk by pressing the HOST button on the Media Options screen.

+ PIs May Retrieve Their Own Data

Principal investigators (PIs) and PI-designated co-workers will now be able to access their proprietary data electronically. Any individual who wants electronic access to his or her own proprietary data must be both a registered and an authorized user of the Archive.

Registration allows access only to non-proprietary data; authorization additionally allows a PI and individuals selected by the PI to have access to the PI's proprietary data. You can become a registered user by filling out the World Wide Web registration form at

http://stdatu.stsci.edu/registration.html

or contact the Archive Hotseat at archive@stsci.edu. To become an authorized user, contact the Archive Hotseat.

Authorization requests will be inspected very carefully. For this reason, authorization, which allows access to proprietary data, may take a little longer than simple registration. We strongly encourage PIs desiring this option to become registered and authorized *well in advance* of the execution of their program.

We also encourage all PIs, whether or not yet registered users of the Archive, to participate in the Archive survey on the World Wide Web. Issues regarding data distribution and electronic access are being decided now with the help of user input via the survey.

+ AutoPI: New Format for GO/GTO Tapes

We're using a new tool to generate GO/GTO tapes: AutoPI. AutoPI automates work formerly done by our human operators, letting them concentrate on quality control. Also, AutoPI allows us to include more information on your tapes. For example, OMS files ("jitter" files) will now be included for every observation on every GO/GTO tape.

+ File Extension Change: .fit to .fits

Files retrieved from the Archive will now carry the extension .fits instead of .fit, to help streamline their use in FITS processing packages.

+ Request Names Will Be Longer

Request names in the Archive will be lengthened, to include the first 16 (instead of 4) characters of your archive username.

-=-

THE HUBBLE DEEP FIELD: AVAILABILTY OF REDUCED DATA

CR-rejected, coadded images for each of the four passbands of the Hubble Deep Field will be made available through anonymous FTP from stdatu.stsci.edu, about the time of the AAS meeting in January. Watch the Archive What's new page for the announcement (http://stdatu.stsci.edu/whats_new.html).

-=-

WWW ACCESS TO THE 2ND-GENERATION DIGITIZED SKY SURVEY

Our popular WWW access to the Digitized Sky Survey now provides an option to retrieve scans from the 2nd Generation of the Palomar Sky Survey. The 2nd Generation Survey is currently an ongoing project, so images from this survey will be loaded into the jukebox as they become available.

-=-

UPGRADE OF STDATU TO SOLARIS 2.4

In December, we'll be upgrading our archive host stdatu.stsci.edu to Solaris 2.4, to allow us to mount a much larger staging disk. This may result in a short period of downtime for stdatu, but we'll try to keep it to a minimum.

HST Archive Documentation

The HST Archive Manual

Provides extensive information on how to access the HST and Multimission archives via two user interfaces, StarView and the World Wide Web. Gives advice on search strategies; higher level functions of StarView; descriptions of StarView screens and the HST catalog; nomenclature convention for HST data.

Version 7.0 of the Archive Manual was released in June 1999.

PDF version (3.9 Mb),

On-line version

Postscript version (gzipped) (2.1 Mb).

Users will find the PDF version more flexible and quicker to use. Loading of some chapters with the on-line version might take some time.

The HST Data Handbook

The comprehensive guide to calibrating, reducing, and analyzing HST data.

Archive Newsletters

The electronic newsletters provide information about the various archives supported by the Multi-mission Archive at STScI (MAST), including HST

Old HST Archive Newsletters [incomplete]:

Hubble Space Telescope

The Medium Deep Survey (MDS) is an international project that uses the Hubble Space Telescope (HST) in Pure parallel mode to study the nature of faint galaxies in the deepest regions of the universe.

This site created by the MDS group at Carnegie Mellon University (CMU) gives access to data from the MDS CDROMS on a Jukebox at the Space telescope Science Institute (STScI). These now non-proprietary post-HST-refurbishment observations cover the period from February 1994 to January 1998. More MDS cdroms will be released when processed.

The released MDS database contains model fits for over 210,000 objects in over 522 WFPC2 fields, observed in most cases using the F814W (498 in I), F606W (358 in V), and for few in F450W (55 in B) photometric filters. Some fields overlap each other and duplicate observations of the same object has not yet been cross-identified.

- CMU MDS group Home-page
- Bibliography of MDS Science Publication
- Documentation
- Search the WFPC2 MDS Database at STScI (Help).
- Direct access to MDS Database on CDROM at STScI
- Clickable MDS Data of Hubble Deep Field North in color
- Top Ten Gravitational lens candidates found by MDS

Please note:
Any use of this data in a publication should reference Ratnatunga, Griffiths and Ostrander **118** 86-107 ; 1999AJ....118...86R, and make the following acknowledgment.

The Medium Deep Survey catalog is based on observations with the NASA/ESA Hubble Space Telescope, obtained at the Space Telescope Science Institute, which is operated by the Association of Universities for Research in Astronomy, Inc., under NASA contract NAS5-26555. The Medium-Deep Survey analysis was funded by the HST WFPC2 Team and STScI grants GO2684, GO6951, GO7536, and GO8384 to Prof. Richard Griffiths and Dr Kavan Ratnatunga at Carnegie Mellon University.

The initial search of database is done from disk. However access to the images and specific files from the cdroms, particularly the load time to access a new cdrom and the image transformations can take an extra minutes.This could sometime timeout the html request giving an almost blank page. Reloading should recover full page. Files and images extracted from cdrom and older than one hour are deleted from the scratch disk space.

The data is provide on the web via this cgi-driver for any preliminary study of what is available on the MDS-CDROMS. Any astronomer wishing to make extensive use of this data should request a CDROM copy. Sets of copies of the CDROMS will be made after we roughly know the demand for them. There are currently 19 CDROMs and the cost of production of a full set is estimated at about US$200/-

Library of *IUE* NEWSIPS SWP Echelle Spectra for White Dwarfs

---

Introduction

This site contains final processed IUE SWP echelle spectra for all 55 hot white dwarfs from the IUE Final Archive. These spectra are processed versions of the 213 NEWSIPS MXHI files as well as all the coadded spectra discussed in Holberg, Barstow and Sion (1998).

This page is organized by the McCook and Sion (1998) WD number for each star. Clicking on the WD number will lead to a list of processed spectra for that star. That list identifies individual processed NEWSIPS spectra for the selected star (by SWP number) and also any coadded spectra which were produced. All spectra are in a standard FITS format which contains wavelength, flux, flux uncertainty, and error flag vectors for the 1150 Angstroms to 1950 Angstroms range. The data set and data analysis procedures are described in Holberg, Barstow and Sion (1998). Spectra can be graphically displayed or retreived as FITS files via ftp.

MAST Prepared Science Products

The following is a listing of sites of highly processed datasets from missions supported by MAST. These are datasets consisting of atlases, images, and/or the data themselves which have been placed on the web either as final data products or as appendices referenced in recent published papers. These data are in the public domain and/or will soon be published. The datasets are organized by type of observation (survey, individual objects, time series) and will include a growing number of catalogs with links to the data and in some cases spectra and/or images.

Deep Sky Surveys

- Hubble Deep Field
- Hubble Deep Field South
- Medium Deep Survey

Wide Field Survey Catalogs

- Magellanic Clouds Planetary Nebulae (HST)
- SDSS Quasar Catalog

Spectral Atlases: multi-object samples

- Ultraviolet Spectral Atlas of Standard Stars (IUE)
- Library of Copernicus Atlases of Selected Stars
- Far-Ultraviolet Spectral Atlas of Stars (EUVE)
- Library of IUE NEWSIPS SWP Echelle Spectra for White Dwarfs
- FOS Composite Quasar Spectrum (FOS)

Spectral Atlases: individual objects

- High S/N GHRS LSA G160M Observations of 10 Lacertae (HST)
- High S/N GHRS SSA Echelle Observations of chi Lupi (HST)
- High S/N GHRS SSA Observations of Chromospheric lines in Procyon (HST)
- High S/N GHRS LSA G270M Observations of alpha Ori (HST)

Time-Dependent Spectra

- Grayscale of Time Variations of gamma Cas near SiIV Doublet (HST)

Guidelines for authors of new prepared science products

Search for: [ ] Submit Options

Perform a search through the text of on-line Web documents. Enter some keywords and press return. Phrases should be enclosed in double quotes or hyphenated.

If you get too many hits, try entering more keywords, changing the proximity control if your keywords should appear together, or excluding terms by preceeding them with a minus sign. For example, to search for exposure time calculators other than the one for NICMOS, try the query

> "exposure time calculator" -nicmos

If you get too few hits, try fewer keywords, and check your spelling. More extensive help is available by following this link:

AURA announces U.S. Gemini Fellowship Award

AURA Dedicates Gemini South Telescope

On January 18th, AURA formally dedicated the Gemini South Telescope completing the Gemini Observatory construction. The Dedication was attended by **President Lagos**, **Rita Colwell**, and other partner representatives. A selection of statements, images, and materials can be found by at the **Gemini Website**.

AURA Establishes Schommer Educational Fund

On December 19, friends and colleagues from around the world commemorated the life and contributions of Bob Schommer who died this month. **Bob Schommer, Director of the U.S. Gemini Science Center**, was known for his dedication to science and his energetic support for Gemini and CTIO users. This site includes statements and testimonials to Bob's contributions to astronomy. In addition, AURA has established the **Schommer Children's Fund** to assist the Schommer family in meeting the future educational expenses of the children Robert, Andrea, and Paulina. Friends and colleagues are invited to contribute to this fund.

First Announcement

Hubble's Science Legacy: Future Optical-UV Astronomy from Space, April 2-5, 2002
University of Chicago

A workshop on the science opportunities, performance requirements and technology developments needed for a large Optical-UV space telescope, in the decade following the de-orbiting of the Hubble Space Telescope when NGST is launched.

Students Operate Mars Odyssey Camera

A group of small, unnamed craters in the Martian southern hemisphere is the first site captured by a group of middle school students who are operating the camera system onboard NASA's Mars Odyssey spacecraft this week. The acquisition of the image marks the beginning of the Mars Student Imaging Project, a science education program funded by NASA and its Jet Propulsion Laboratory, Pasadena, Calif., and operated by the Mars Education Program at Arizona State University, Tempe. The project gives thousands of fifth to 12th grade students the opportunity to do real-life planetary exploration and to study planetary geology using Odyssey's visible-light camera. (Full Story)

IRAF
Image Reduction and Analysis Facility

Welcome to the IRAF Homepage! *IRAF* is the Image Reduction and Analysis Facility, a general purpose software system for the reduction and analysis of astronomical data. IRAF is written and supported by the IRAF programming group at the National Optical Astronomy Observatories (NOAO) in Tucson, Arizona. NOAO is operated by the Association of Universities for Research in Astronomy (AURA), Inc. under cooperative agreement with the National Science Foundation

News!

- Online CD-ROM Order Form
- IRAF V2.11 Release Notes
- April 1998 IRAF Newsletter

What is it? How do I get it?

IRAF is the "Image Reduction and Analysis Facility". The main IRAF distribution includes a good selection of programs for general image processing and graphics, plus a large number of programs for the reduction and analysis of optical and IR astronomy data (the "noao" packages). Other external or layered packages are available for applications such as data acquisition or handling data from other observatories and wavelength regimes such as the Hubble Space Telescope (optical), EUVE (extreme ultra-violet), or ROSAT and AXAF (X-ray). These external packages are distributed separately from the main IRAF distribution but can be easily installed. The IRAF system also includes a complete programming environment for scientific applications, which includes a programmable Command Language scripting facility, the IMFORT Fortran/C programming interface, and the full SPP/VOS programming environment in which the portable IRAF system and all applications are written.

IRAF is freely available on all platforms via anonymous ftp to our server at iraf.noao.edu or for a small cost it may be ordered on tape or CD-ROM. If you are unsure about whether IRAF can help you, we have a FAQ (frequently-asked questions list) to answer this particular question.

How to Contact Us:

IRAF Site Support is available to help users with problems or questions installing or using the system. Electronic mail is logged to guarantee a reply and questions are usually answered within 24 hours. If you can't find the answers you need in this document or our FAQ feel free to contact us by whichever means is most convenient:

- E-mail - **iraf@noao.edu** or **noao::iraf**
- Hotline - **(520) 318-8160** FAX - **(520) 318-8360**

Users may also send questions to the ADASS newsgroups. This is encouraged especially for general interest questions and discussions, site-specific problems should probably be sent to us by email although they will still be answered if posted.

Other Projects Using IRAF

IRAF is in use by thousands of astronomers at more than 1500 sites world-wide. Some of the larger projects using IRAF include:

- AXAF - Advanced X-ray Astrophysics Facility
- EUVE - Extreme Ultraviolet Explorer
- FTOOLS - FITS utility package from HEASARC
- GONG - Global Oscillation Network Group
- PROS - ROSAT XRAY Data Analysis System
- STSDAS - Space Telescope Science Data Analysis System

STSDAS Space Telescope Science Data Analysis System

Calibration and analysis software for Hubble Space Telescope data

Introduction to STSDAS

Versions and Packages

In addition to STSDAS, the STSDAS Group maintains additional software that is provided as external packages in the IRAF environment. The major external packages that you will find on STEIS include:

- TABLES
- HST_PIPELINE
- VDISPLAY

The current version of STSDAS is V2.3; The current version of TABLES is also V2.3. *You must install TABLES before installing STSDAS.*

STSDAS Package Organization

Programs in STSDAS are called *tasks*. Tasks are grouped by function into *packages*. Some of the major packages in STSDAS include:

analysis
fitsio
graphics
hst_calib
toolbox

More than 400 tasks comprise STSDAS V2.0.

PyRAF Home Page

PyRAF is a new command language for IRAF based on the Python scripting language. It is useful both for interactive data analysis and for writing analysis scripts. PyRAF coexists with the current IRAF CL; no changes need be (or should be) made to your installed IRAF system to use it. PyRAF has been developed by the Science Software Group at the Space Telescope Science Institute.

What is PyRAF?	A detailed overview of why we developed PyRAF, what it is good for, and what our general plans are.
The PyRAF Tutorial	Currently the best (and only :-) documentation on how to use PyRAF.
Learning more about Python	
• **Quick Tour**	A mini-tutorial on the key features of Python, with pointers to sources for further information.
• **Intro to Python - viewgraphs (PDF)**	Viewgraphs from an introductory lecture on Python.
• **Documentation & Books**	This is a link to a list of available tutorials and books on Python.
• **Index of Python Modules**	This is a link to pydoc created web pages of all Python modules installed at the STScI.
Download PyRAF Beta Version	PyRAF v0.9.1 (Last updated 2001 Dec 14) NEW! Information on what was recently fixed.
Register for PyRAF Beta Version	Use this form to register to receive notification when a new version of PyRAF will be ready for downloading.
PyRAF News	News about PyRAF (last updated 2001 December 6).
Frequently Asked Questions	Follow the link at the top to search the FAQ (though currently the list is short.)
Important Information for PyRAF Beta Testers	Desired feedback, future release plans.
Known Shortcomings, Differences from IRAF, Planned Improvements, and Bugs	Summary of known bugs and limitations of current version of PyRAF, differences from the IRAF CL, and a sketch of plans for the future.
Python software at STScI	Python, PyRAF, PyFITS, NumArray, 3rd party libraries: versions and configuration at STScI.

Proposing to Use HST

The Cycle 11 Call for Proposals

The Call for Proposals describes the policies and procedures for proposing to use HST.

The proposal process

Read a brief description of proposal preparation process -- from the initial Call for Proposals (CP) to final acceptance of a Phase II proposal.

Requests for Director's Discretionary Time

Up to 10% of the available HST observing time may be reserved for Director's Discretionary (DD) allocation. A DD proposal is appropriate when a truly unexpected transient phenomenon occurs or when developments since the last proposal cycle make a time-critical observation necessary. Check the DD proposal submission page for details.

Getting STSDAS and TABLES Software

Before You Begin...

STSDAS runs in the IRAF environment. If you do not already have IRAF installed on your local system, you will need to get and install IRAF before installing STSDAS. If you do not have IRAF, you can retrieve it from The IRAF group at NOAO.

STSDAS v2.3 was tested under IRAF v2.11.3. IRAF v2.11.3 is currently available for the follow platforms:

- Solaris V5.5.1
- Solaris V5.8
- SunOS 4.1.3
- Red Hat 6.1
- Slackware 3.3
- FreeBSD 2.2.5
- DEC Alpha - Digital Unix (OSF1) V5.1
- HP-UX B.10.20
- SGI IRIX 6.5

Summary of the installation instructions:

Complete installation instructions and information for system administrators is provided in the PostScript file, *STSDAS Site Manager's Installation Guide and Reference*.

Please register your site as an STSDAS user when you install the software. This will enable us to keep you informed of software upgrades and other information. The registration form also contains check boxes that can be used to request STSDAS software on magnetic tape.

If you have any problems with the installation or software retrieval, contact the STScI Help Desk: `help@stsci.edu`

Getting STSDAS and TABLES

There are a number of ways to get the files over the network:

STSDAS

**** Current version ****

- Retrieve STSDAS V2.3 pre-compiled binaries in a series of split compressed tar file s.
- Retrieve STSDAS V2.3 source code in a series of split compressed tar files.
- Retrieve STSDAS V2.3 source code in one large compressed tar file.

**** Older versions ****

- Retrieve STSDAS V2.2 source code in a series of split compressed tar files.
- Retrieve STSDAS V2.2 source code in one large compressed tar files.
- Retrieve STSDAS V2.1.1 source code in a series of split compressed tar files.
- Retrieve STSDAS V2.1 source code in a series of split compressed tar files.
- Retrieve STSDAS V2.0.2 source code in a series of split compressed tar files.
- Retrieve STSDAS V2.0.1 source code in a series of split compressed tar files.
- Retrieve STSDAS V2.0 source code in a series of split compressed tar files.
- Retrieve STSDAS V1.3 source code in a series of split compressed tar files.

TABLES

**** Current version ****

- Retrieve TABLES V2.3 pre-compiled binaries in a series of split compressed tar files.
- Retrieve TABLES V2.3 source code in a series of split compressed tar files.
- Retrieve TABLES V2.3 source code in one large compressed tar file.

**** Older versions ****

- Retrieve TABLES V2.2 source code in a series of split compressed tar files.
- Retrieve TABLES V2.2 source code in one large compressed tar files.
- Retrieve TABLES V2.1.1 source code in a series of split compressed tar files.
- Retrieve TABLES V2.1 source code in a series of split compressed tar files.
- Retrieve TABLES V2.0.2 source code in a series of split compressed tar files.
- Retrieve TABLES V2.0.1 source code in a series of split compressed tar files.
- Retrieve TABLES V2.0 source code in a series of split compressed tar files.
- Retrieve TABLES V1.3 source code in a series of split compressed tar files.

Back to the STSDAS Page

STSDAS Space Telescope Science Data Analysis System

Calibration and analysis software for Hubble Space Telescope data

Historical progression of news in STSDAS

This page is chronologically ordered from the top down. There should be a date at the end of each item that indicates when it was added to the page.

The links in this page are NOT as new as those in the STSDAS page.

Modified 17 May 2001

The ST-ECF Post-Operational Archives group has released Version 1.1 (May 2001) of the STPOA package. STPOA is an IRAF layered package which currently offers improved calibration for FOS data. In the future, this package will contain other HST post-operational instrument calibration software. Information regarding this package can be acquired from ST-ECF.

The ST-ECF Post-Operational Archives group has released the first version of the STPOA package. STPOA is an IRAF layered package which offers improved calibration for FOS data. Information regarding this package can be acquired from ST-ECF. 21 August 2000

Announcing the RELEASE of STSDAS/TABLES v2.2 . Go to the Downloading STSDAS/TABLES software section to download the source code and/or binaries. 18 August 2000

Announcing the RELEASE of STSDAS/TABLES v2.2 . Go to the Downloading STSDAS/TABLES software section to download the source code and/or binaries. 18 August 2000

C Interface to the IRAF Virtual Operating System (CVOS). The CVOS allows one to program tasks in C which have the added advantage of being able to use IRAF functionality. 07 Janua ry 2000

STSDAS/TABLES v2.1.1 has been released. The Release notes for v2.1.1 can be read at this link. 09 December 1999

STSDAS/TABLES v2.1 was released. The Release notes for v2.1 can be read at this link. 09 October 1999

There are the draft release notes for the upcoming STSDAS/TABLES 2.1 release. We expect to be releasing STSDAS/TABLES 2.1 by the end of September. 23 September 1999 Plans for Future Support of STSDAS/TABLES on OpenVMS. 28 July 1999

Synphot Users Guide version 2.1 in PostScript form. Syntax throughout the manual reflects the most recent expression evaluator. Expanded appendixes describing instrument keywords, libraries, etc. Updated task descriptions to reflect new, obsolete, and modified tasks. 28 December 1998

Upgrades to calstis (v2.0) . 20 November 1998

Upgrade to the gcombine package in STSDAS v2.0.2

The release of **STSDAS/TABLES v2.0.2** is complete for those platforms that support IRAF v2.11.1 06 October 1998

Upgrade to SYNPHOT package , a patch that includes bug fixes for the LINUX platforms. 05 August 1998

Upgrades to calstis (v1.9) . 30 July 1998

Upgrades to the calnica(v. 3.2) and calnicb (v2.2) packages. 24 July 1998

Upgrade to the calfos(v3.0) package in STSDAS v2.0.1; includes upgrades to support spectropolarimetry. 14 July 1998

Upgrade to the calstis(v1.8) package in STSDAS v2.0.1; includes includes new task ocrreject, tastis and includes major pipeline fixes. Also minor fixes to defringe, mkfringeflat, normspflat, prepspec. 14 July 1998

Upgrade to the *dither* package in STSDAS v2.0.1 29 May 1998

Upgrade to the *calstis(v1.8)* package in STSDAS v2.0.1; includes new tasks ocrreject, tastis and includes major pipeline fixes. 22 May 1998

Upgrade to the *paperprod(v2.24)* package in STSDAS v2.0.1; includes several fixes to the STIS, NICMOS and WFPC2 Paper Products. 22 May 1998

The release of **STSDAS/TABLES v2.0.1** is complete for those platforms that support IRAF v2.11 24 March 1998

Upgrade to the *calnica(v3.1)* package in STSDAS v2.0 now recognizes the new Target Acquistion filenames. 29 December 1997

Upgrade to the *contrib* package in STSDAS v2.0 now includes the new task 'slitless' for reduction of grism observations. 29 December 1997

Upgrade to the *calstis(v1.5a)* package in STSDAS v2.0 includes the new task echplot and includes some small bugs fixes. 16 October 1997

STSDAS/TABLES 2.0 Released

A Major upgrade to STSDAS/TABLES has been released for machines running Solaris V2.4 and SunOS 4.1 (or greater). STSDAS/TABLES 2.0 requires IRAF 2.11. 12 September 1997

Update of Synphot manual Synphot Users Guide version 2.0 in PostScript form. Syntax throughout the manual reflects the most recent expression evaluator. Expanded appendixes describing instrument keywords, libraries, etc. Updated task descriptions to reflect new, obsolete, and modified tasks. 31 August 1997

User's Guide to FITS kernel STScI User's Guide to the FITS Kernel. The IRAF Fits kernel, developed at STScI and NOAO, is in use on some systems at our site. This document provides a general guide for use of this kernel. 28 March 1997

STSDAS version 1.3.5 is layered on IRAF version 2.10 and TABLES version 1.3.4. 25 July 1996

STSDAS and TABLES version 1.3.4 are layered on IRAF version 2.10. STSDAS is layered on TABLES. 05 October 1995

User Support Changes

Synphot Users Guide version 1.3.3 updated

Syntax throughout the manual reflects the most recent expression evaluator. Expanded appendixes describing instrument keywords, libraries, etc. Updated task descriptions to reflect new, obsolete, and modified tasks. 31 March 1995

STSDAS and TABLES version 1.3.3 are layered on IRAF version 2.10. STSDAS is layered on TABLES. 17 March 1995

The Hubble Deep Field: latest news

1/2/01

The Hubble Deep Fields at the Rome Observatory.

1/2/01

European VLBI Network observations of the HDF-N.

9/1/00

Westerbork Synthesis Radio Telescope1.4 GHz observations.

4/20/00

First x-ray results from Chandra HDF Observations are now available.

10/19/98

The VLA survey of the HDF and flanking fieldsnow has its own web site.

6/29/98

Hawaii Flanking Field Catalog.Includes astrometry, photometry, redshifts, and H&K band infrared images.

6/3/98

A New Catalog of Photometric Redshifts in the HDF (Fernandez-Soto, Lanzetta, and Yahil 1998, ApJ submitted).

10/22/97

The link to the HDF South page has been added.

7/23/97

The ISO HDF web page has been updated to include copies of the accepted papers (I-V), active catalogs, tests of the reliability of sources, and other items of interest.

5/12/97

Hubble Deep Field Academy-- Educational Resource for Middle School students

12/12/96

The topic of the 1997 STScI May Symposium will be the Hubble Deep Field.

12/05/96

Data and Preprints of the ISO HDF observationsare now available.

11/26/96

A search of the STScI library STEPsheet reveals the following HDF Preprints and Publications.If yours is not listed here, please send a copy to the STScI Librarian (Librarian, Space Telescope Science Institute, 3700 San Martin Drive, Baltimore, MD 21218).

11/3/96

Infrared followup obervationsusing the KPNO IRIM camera are now available.

A new set of WFPC-2 mosaics are available courtesy of Mark Dickinson and Richard Hook. The World Coordinate System (WCS) keywords in the mosaics and in the IRIM data have been updated to match the system defined in Williams et al (1996, AJ, 112, 1335) based on radio interferometric positions for several HDF sources. An iraf script hdf_wcs_fix.cl is available to updated the header information in the version 2 drizzled images.

To make room for the mosaics, we have deleted the version-1 HST WFPC images from the archive disk. The v2 images (still available) should be better for most purposes. If (for some peculiar reason) you want the v1 images, you may request a tape from ferguson@stsci.edu.

10/14/96

The Hawaii Active Catalog provides a cursor-driven interface to information on individual HDF galaxies.

9/25/96

Plans are underway for a southern HDF. There is no specific date or field yet for the observations. Fields under consideration are being searched for a suitable QSO for absorption line studies.

The topic for the 1997 STScI May Symposium will be the Hubble Deep Field. Dates are still to be determined. Further details will be announced here, through mailings, and on the STScI meetings web page.

Preprints from the VLA survey are available: abstract; postscript ; figure 1; figure 2.

Redshiftsfrom the DEEP project survey with Keck are now available.

There is now a web page for the ISO HDF followup observations.

9/22/96

The Drizzlealgorithm used to reduce the HDF is now publicly available in a beta release version.

7/31/96

The Version 2 catalogs have finally been put on the web. Details of the STScI & ST-ECF data reduction, source detection, and photometry are described in Williams et al. (AJ, in press).

6/28/96

SUNY Stony Brook now has an HDF Web page.

6/17/96

The Berkeley HDF group now has a web page, listing, among other things redshifts for about 30 galaxies in the HDF and flanking fields.

Redshifts from the Caltech and Hawaii Keck runs have been added to the Caltech web page.

Astrometry of the HDF flanking fields has been carried out by the DEEP collaboration.

HDF version 3 has slowed considerably, mostly because it is not a high priority given the modest expected gains in resolution and S/N. The new target date is the end of the summer

A cautionary note on photometry. The zeropoints listed for the HDF do not include a correction for contamination, which progressively adds attenuation between monthly decontaminations (warmups) of WFPC-2. As the HDF was taken shortly after a DECON, this effect is less than 0.05 mag for F300W, and significantly less for the redder filters. The F300W correction will be posted here once it is computed.

A more serious concern is that the F300W exposures, which have low backgrounds and low source count rates, are in a regime where charge-transfer effects (CTE) could be significant. Measured magnitudes of faint sources in the F300W band could be up to 0.2 mag fainter than true magnitudes, with the size of the effect depending on row number. The effect is probably only a few hundredths of a mag for the optical filters because of their higher backgrounds. Laboratory tests and observations in Cycle 6 are being planned to try to arrive at a calibration of CTE as a function of row number, source count rate, background level, the number of counts in the previous image, and the time elapsed between images. Details of recent investigations of the CTE and (and a similar, probably related photometric dependence on exposure time) are posted on the WFPC-2 advisory page.

5/20/96

A TIFF format imageof the HDF + flanking fields, overlaid on a KPNO 4-m image has been added, for use a finder chart. CAUTION -- the frames in this image were aligned by eye. Has anyone in the greater HDF community yet done a precise registration of the HDF and flanking fields?

Added an update on J, H, and K band observations from the KPNO 4-m telescope.

5/3/96

New links to HDF followup at Cambridge and Lick Observatory have been added to the clearinghouse.

Our new target date for version 3 of the data reduction is now the end of May.

4/16/96

Well, the superdarks & superbiases are almost done...version 3 is probably still several weeks down the road, as there are quite a few other issues that have to be addressed in this final reduction.

Sky levels for the individual chips are now posted.

3/28/96

It is now clear that we will miss the April 1 target date for the version 3 release of the HDF data. We are in the midst of remaking superdarks and superbiases, correcting at the same time for the MgF faceplate glow. We are shooting for April 15.

3/20/96

Information on VLA observationshas been added to the HDF clearinghouse.

3/13/96

There is a problem in the World Coordinate System (WCS) in the version 2 images. The v2 image headers have had a lot of stuff stripped out of them that was in the v1 edition. 99% of that information was useless, but two keywords pertaining to the WCS were not. The parameters CTYPE1 and CTYPE2 should be set to 'RA---TAN' and 'DEC--TAN', respectively (note the number of dashes in each entry!). Currently, they are incorrectly set to 'PIXEL'.

3/7/96

The weight images in Version 2 give the inverse variance of the images in counts per second per INPUT (WF- or PC-sized) pixel. However, when you measure the noise in the drizzled images, you will be measuring it in counts per second per OUTPUT pixel. The ratio of areas (and therefore counts) between the input and output pixels is 6.25 in the WF and 1.31 in the PC. As a result the standard deviation estimated from 1./sqrt(weight) must be divided by the ratio of areas before comparison with the noise measured in the images.

3/4/96

A list of frames not used version 2 has been added.

2/29/96

Version 2 of the HDF data is now available. The additional processing has resulted in roughly a 10% improvement in S/N for the F450, F606, and F814W filters.

2/28/96

Information on image registration and combination and on the drizzle algortihm have been updated in preparation for the expected release of Version 2 on 29 Feb 1996 (what would we have done were it not a leap year?).

2/24/96

Proposals are now being solicited for ISO observations of the Hubble Deep Field. Up-to-date information about the ISO mission and instruments can be found on the ISO Homepage. Detailed information about the HDF proposal opportunity is on the same HomePage under the heading "ISO and the Hubble Deep Field".

2/21/96

Version 2 is just about ready. Really. The final scattered light subtraction is being done today.

2/20/96

Added a link to the University of Hawaii HDF web pageprovided by Len Cowie.

2/7/96

Flanking Field images. 1 & 2 orbit exposures of 8 adjacent fields have been installed on the ftp site.

1/30/96

Version 2 of the data is running a bit behind. We had hoped to have it ready Feb. 1, but it now looks like Feb. 8 is a better bet. The masking of moving targets is almost complete. Then the frames will be restacked, redrizzled, and will have scattered light subtracted.

1/25/96

The ESO/ECF HDF groupnow has a link in the HDF clearinghouse.

1/19/96

A link to the call for HDF archival proposals has been added. The deadline is March 15, 1996.

1/16/96

The catalogs released on January 15 had an error in the x,y and RA, DEC coordinates. They have been corrected and re-released January 16. The new versions will be stored as FITS tables (*.fits) rather than stsdas tables (*.tab), but may not propagate to the ftp site until mid-day on January 16.

1/14/96

HDF web pages are installed, but many are incomplete and will remain so until January 20th or so. If you have questions, contact the undersigned.

Harry Ferguson ferguson@stsci.edu
Andy Fruchter fruchter@stsci.edu

The Hubble Deep Field: Background

The Hubble Deep Field (HDF) is a Director's Discretionary program on HST in Cycle 5 to image a typical field at high galactic latitude in four wavelength passbands as deeply as reasonably possible. In order to optimize observing in the time available, a field in the northern continuous viewing zone (CVZ) was selected and images were taken for 10 consecutive days, or approximately 150 orbits. Shorter 1-orbit images were also obtained of the fields immediately adjacent to the primary HDF in order to facilitate spectroscopic follow-up by ground-based telescopes. The observations were carried out from 18-30 December 1995, and the data are available to the community for study.

with PA_V3=112d which corresponds to U3 ORIENT=292D
```

The Hubble Deep Field Data Products:

Quick summary

Raw Data	Can be extracted from the HST archive.
Version 1	No longer available on line. We recommend using version 2.
Version 2	Final reduced images and catalogs.

The HDF data were released for general use on January 15, 1996. We have tried to anticipate the needs and desires of most astronomers, while keeping the data volume reasonable. The data products, from least processed to most processed, are listed below. The data volume, even for final images, is considerable. To reduce the load on the STScI ftp site and speed data transfer in other parts of the world, several sites have agreed to mirror the STScI data repository. Check their web pages for details on how to transfer the data.

Other HDF data sites: ST-ECF (Germany); CADC (Canada); and UKHST (UK).

- **Raw data.** Available January 15, 1996.

  This is essentially as received from the telescope, with all the cosmic rays, hot pixels, and other defects. It will probably not be useful for most people. This is best obtained on exabyte tape, as it consists of roughly 3 Gbytes of data. Request a tape by sending email to archive@stsci.edu. (The raw data can also be extracted over the internet from the HST archive, but this will be prohibitively slow for the whole data set.)

- **Version 1.** Available January 15, 1996. As of November 1, 1996, these data are no longer available on line. We recommend the use of version 2 data.

  These data reflect processing up to January 15, 1996. A number of shortcutswere taken to make these data available within three weeks of the last observation.

- **Version 2.** Available February 29, 1996.

  Essentially all of the data have been used in the final stacks, and the images have been combined with weights that are optimal for faint sources.

Harry Ferguson ferguson@stsci.edu 10/09/01

HDF Observing logs and ancillary information

- Master list of observations.
- Photometric zeropoints.
- Sky levels for each chip in version 2.
- Shifts between dither positions.
- Shifts between filters in the version 1 drizzled images.
- Unused frames in version 2
- Version 2 summed exposure times

Harry Ferguson ferguson@stsci.edu 1/14/96

The HDF Pipeline:

HDF data were reduced with the same software as the standard HST pipeline (the STSDAS task calwp2), but with different calibration files, and with a slightly different treatment of the darktime. After pipeline processing, the data were stacked and cosmic rays were identified. Hot pixels were identified from dark frames and from the images themselves. Details are listed below.

- **superbiases.**
- **superdarks.**
- **flats.**
- **cosmic ray rejection.**
- **image stacking.**
- **hot pixel rejection.**
- **scattered light subtraction.**

There is room for improvement in all these procedures. A number of shortcuts were taken in the initial processing of the data. Our plans for reprocessing the data are evolving daily, and we would appreciate any comments.

Harry Ferguson ferguson@stsci.edu 1/14/96

HDF Image Registration and Combination

The HDF observations were carried out with roughly 9 different pointing positions per filter, spaning a scale of roughly 2 arcseconds. The primary purpose of ``dithering'' in such a fashion is to smooth out flatfielding uncertainties. A secondary purpose is to try to recover some of the information lost due to the undersampling of the WF detectors.

After having been fed through the pipeline, the registration of the individual images was checked by comparing the positions of several bright sources. This revealed a couple of unexpected large (0.8 arcsec) shifts, but otherwise suggested that the images at each dither position were registered well to within the errors of such a comparison. The images with the large shifts have been treated as separate dither positions. Subsequent tests have revealed small (~0.1 pixel) shifts between some frames that were nominally at the same dither position. These positional errors have not yet been corrected; however, their influence on the final image is expected to be negligible.

The roughly 5 images per dither position were cosmic-ray rejected and stacked into a single image. Shifts and rotations between these dither stacks were measured using a specially written cross-correlation task. Estimated errors are a few hundredths of a pixel for F450W, F606W, and F814W. Only two dither positions -- those produced by the unexpected shifts -- showed any measurable rotation.

Once the shifts and rotations were measured, the images were aligned and combined using the drizzle algorithm, which corrects for geometric distortion, and produces an output image that is sampled on a smaller pixel scale than the input images. The final pixel scale is 0.04 arcsec for both the WF and the PC chips.

Harry Ferguson ferguson@stsci.edu
Andy Fruchter fruchter@stsci.edu 2/28/96

HDF source detection and photometry

The catalogs released on January 15 had an error in the x,y and RA, DEC coordinates. They have been corrected and re-released January 16. The new versions will be stored as FITS tables (*.fits) rather than stsdas tables (*.tab), but may not propagate to the ftp site until mid-day on January 16.

In any event, the catalogs are released with a huge *caveat emptor*. We expect to replace these preliminary catalogs with more trustworthy ones within a few weeks. We would also be happy to archive any catalogs that others produce with different software or source detection algorithms.

The catalogs are available as FITS files of stsdas tables by anonymous ftp from stdatu.stsci.edu.

A brief description of the catalogs can be found in the README file.

The source detection and photometry were carried out with a revised version of FOCAS (Tyson and Jarvis 1979), created by Kurt Adelberger and Chuck Steidel at Caltech. This program is still in the testing phase, but has many improvements over previous versions. The program works by smoothing the data with a fixed kernel, typically the width of the PSF, and then searching for pixels more than a certain number of sigma above the local sky background.

Our source detection and photometry were carried out on the drizzled images. Source detection was done using the sum of the F606W and F814W images to provide the maximum limiting depth. The kernel was an HST psf derived from a star in the field. The minimum area required for detection was 16 continguous drizzled above (0.04 arcsec) above the detection threshold. For the catalog presented here, we have set the threshold fairly conservatively at 5-sigma.

Warnings

These catalogs were made at the very last minute before the AAS meeting. We recommend that you use them only as a comparison to your experiments with object detection. A visual inspection suggests that the catalog is not too bad -- the main problem seems to be oversplitting in general, and big clouds of spurious objects surrounding bright galaxies. It is possible that some fine tuning of the FOCAS "significance" parameter can help in avoiding these things. In isolated areas FOCAS appears to be finding most of the sources and not introducing too many spurious ones.

FOCAS detection and photometry rely heavily on detailed knowledge of the noise properties of the image. The drizzling process introduces correlated noise between pixels that is not yet fully understood. Therefore the formal significance of the detections and the uncertainties on the magnitudes must be taken with a grain of salt.

Harry Ferguson ferguson@stsci.edu 1/14/96

HDF Clearinghouse

While there is likely to be lively competition in interpreting the HDF images and carrying out follow up observations, it is our hope that there will not be much needless duplication of effort. To this end, we invite anyone contemplating followup observations or detailed analysis to share information through the HDF web page. In other words, we will provide pointers to other web locations that describe research on the HDF. The aim is to establish a forum for publicizing the status of followup work in order to avoid too much duplication, and to provide points of contact for cooperation/collaboration between various investigators. If you are interested in participating, please contact ferguson@stsci.edu.

Amazing Space
Galaxies Galore
UPDATED! Mission Mastermind
Star Light, Star Bright
Galileo to HST
Solar System Trading Cards
The Truth About Black Holes
Hubble Deep Field Academy
Comets
Galaxy Hunter NEW!

Amazing Space is a set of web-based activities primarily designed for classroom use, but made available for all to enjoy.

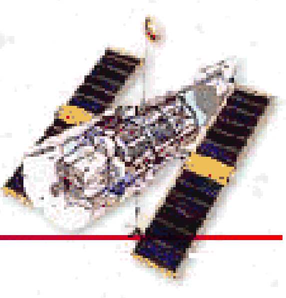
Current activities include:

- Be the Mastermind Behind the Mission! Reconstruct the order of events for Hubble Space Telescope's 2002 Servicing Mission.
  NOTE: This activity is an update of and a replacement for Astronaut Challenge.
- Explore the Hubble Deep Fields from a statistical point of view in Galaxy Hunter: A Cosmic Photo Safari.
- Whip up a batch of Comets--without trashing the kitchen!
- Fall into one of the eeriest celestial phenomena in The Truth about Black Holes
- Play with the building blocks of the universe, galaxies, in Galaxies Galore
- Find out what light and color can tell you about stars in Star Light, Star Bright
- Learn about the objects that make up the Solar System by collecting Solar System Trading Cards
- Train to be a scientist by enrolling in the Hubble Deep Field Academy.
- Brief history of telescopes from Galileo to the Hubble Space Telescope.
- Did An Activity? Tell us what you think.
- Want to preview soon-to-be-released activities? Join First Contact.

Learn more about the *Amazing Space* project.

Press Releases and other information for the general public.

Visit the Space Telescope Science Institute



What's New

After Data Release

- The Hubble Deep Fields at the Rome Observatory (January 2, 2001).
- In addition to the final combined NICMOS version 1 images that were already released on November 23, 1998, all individual calibrated (un-combined, un-mosaiced) NICMOS exposures are now also available for downloading as gzipped tar files (March 11, 1999).
- Updated the absorption line list for the QSO J2233-606 sight-line (March 5, 1999).
- Updated the list of HDF-S related references (March 5, 1999).
- Added links to the full text of some of the HDF-S related poster papers at the AAS meeting in Austin to the list of HDF-S related references (January 7, 1999).
- Added some links to technical information on the page describing the HDF-S Catalogs (December 23, 1998).
- Updated the page with file names to include the most recently added data products (December 23, 1998).
- HDF-S Catalogs are now available (December 21, 1998).
- Version 1b STIS G230L spectroscopic data are now available. This release fixes an error in the wavelength sscale of the version 1 release. Go to the Data Products page for information and data retrieval (December 21, 1998).
- Final data products for all of the WFPC-2 Flanking fields are now available, including the observations in the F606W and F814W bands taken during the 9 orbits when STIS was observing the NICMOS prime HDF-S field. Go to the Data Products page for information and data retrieval (December 21, 1998).
- Added a link to Stephen Gwyn's photometric HDF-S redshifts page on the HDF-S clearinghouse page (December 15, 1998).
- Added a link to the web site of the HDF-S group at UC Berkeley on the HDF-S clearinghouse page, and also a link to their paper Benitez et al. on the page with HDF-S related references (December 12, 1998).
- Added a link to the web site of the ESO Imaging Survey observations of the HDF-S, on the HDF-S clearinghouse page (December 7, 1998).
- Included a detailed description of the NICMOS data reduction (December 5, 1998).
- Updated the WFPC2 discussion on the Observing Strategy page (December 2, 1998).
- Added an extra column (`USED') to the NICMOS main-field observing log and the NICMOS flanking fields observing log (November 30, 1998).
- Added a link to the web site of the HDF-S group at SUNY, Stony Brook, on the HDF-S clearinghouse page (November 29, 1998).
- Added a page with links to Press Reports on the HDF_S (November 29, 1998).
- Final data products for all but one of the WFPC-2 Flanking fields are now available. Go to the Data Products page for information and data retrieval (November 25, 1998).
- Split up the NICMOS Master Observing Log into a main-field log and a flanking field log (November 24, 1998).
- Added a page with Warnings and Advisories (November 24, 1998).
- Added a section on PSF Convolution of the STIS Image to the NICMOS Data Reduction / Technical Information page, and to the README file in the nicmos/ directory on the ftp area (November 24, 1998).
- Added a page with a bare listing of all .html files on the HDF-S web site (November 23, 1998).
- Added the NICMOS Master Observing Log (November 23, 1998).
- Detailed plot added of the HST/STIS spectrum of QSO J2233-606 (November 23, 1998).

At Data Release (November 23, 1998)

- Major upgrade of the entire HDF-S web site associated with the release of the HDF-S campaign data (November 23, 1998).
  - Release of HDF-S Data Products.
  - Addition of pages on observing details, and data reduction and technical issues.
  - Addition of (links to) Public outreach materials and release pictures.
  - Addition of a page with references to HDF-S related publications.
  - Layout and content changes in most of the existing pages.

Before Data Release

- Added a link to the ESO VLT Science Verification Data of the HDF-S on the HDF-S clearinghouse page (October 7, 1998).
- Added a link to the AAO HDF-S observations page on the HDF-S clearinghouse page. Includes an AAT UCLES echelle spectrum of the quasar from 3530-4390A (October 7, 1998).
- Added a link to the ESO HDF-S project page on the HDF-S clearinghouse page (July 15, 1998).
- Updated coordinates of NIC3 field (July 2, 1998).
- Updated HDF-S working group members list (July 1, 1998).
- Updated HDF-S project description (July 1, 1998).
- Added HDF-S clearinghouse page, with addition of links to AAO, ANU, ESO NTT, ISO and AAT PF observations (February 1998 to June 1998).
- Improved NIC3 FOV overlay on CTIO image (January 7, 1998).
- Raw, pipeline calibrated and reprocessed *TEST* observations of the HDF-S (November 1997 to January 1998).

This page was last updated on March 11, 1999.

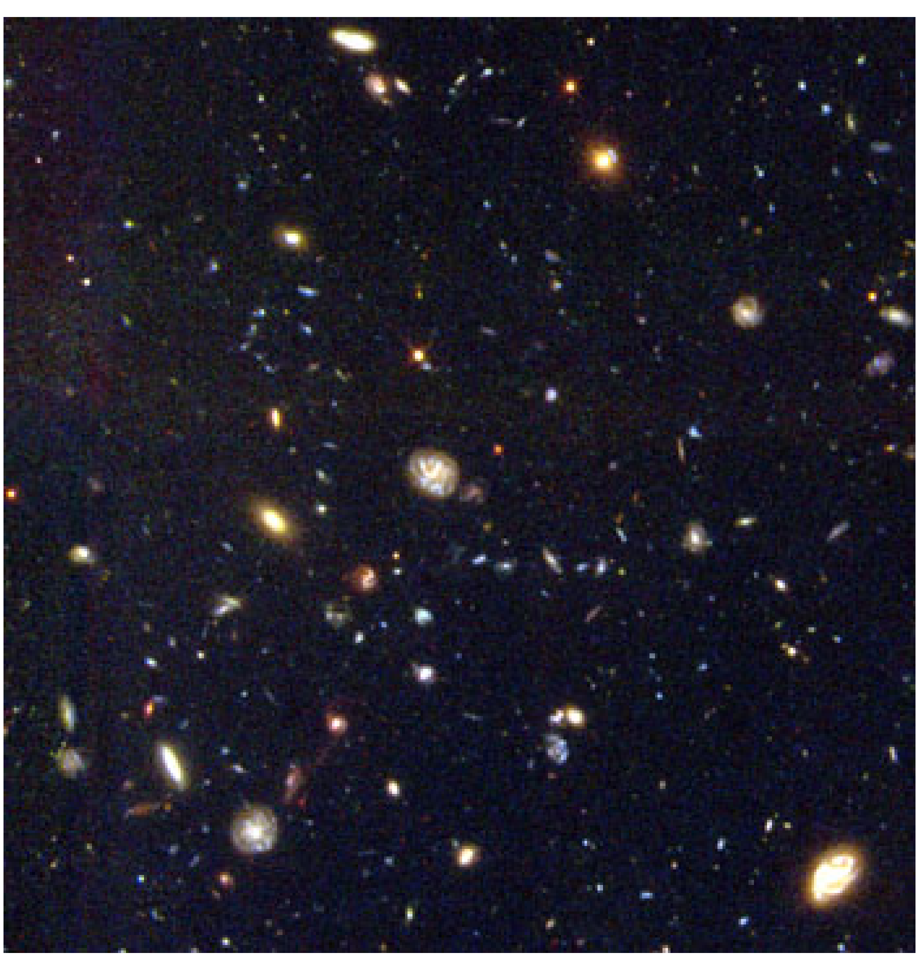
The Universe "Down Under" Is The Target of Hubble's Latest Deep-View



Turning its penetrating vision toward southern skies, NASA's Hubble Space Telescope has peered down a 12 billion light-year long corridor loaded with a dazzling assortment of thousands of never-before seen galaxies. The observation called the Hubble Deep Field South (HDF-S) doubles the number of far-flung galaxies available to astronomers for deciphering the history of the universe.

Office of Public Outreach -- outreach@stsci.edu

Data Products

Final Calibrated, Co-added, Reprocessed Data Products

- WFPC2
  - Images: version1, version2
  - Catalogs: Version 1 HDF-S, HDF-N
- STIS
  - Images: 50CCD, F28X50LP, MAMA
  - Spectra: E230M, G140L, G230L, G430M
  - Catalogs: v1catalog
- NICMOS
  - Images: Camera 3
  - Catalog: Version1
- Flanking Fields
  WFPC2, STIS

Check the file name legend for a listing and explanation of the adopted naming conventions.

Check the instrument specific technical pages for a description of the data products and the implemented data reduction steps: STIS , WFPC2 , NICMOS , Flanking Fields .

Check the pages on observational details for information on observing strategy and individual data sets.

Check the page with warnings and advisories before making any use of the data.

Individual Raw and Calibrated Data from the HST archive

For logistical reasons, the Hubble Deep Field South observations were split over 6 different proposals. Click below to extract a listing of the observations in the Hubble Data Archive for each of the proposals. These listings give information on individual datasets in the HDF-S campaign, and allow you to retrieve individual raw or calibrated datasets. You may also want to study the Phase 2 Proposal Information for the HDF-S proposals.

Project Description

Overview

In December, 1995 the Hubble Space Telescope pointed at an undistinguished high-galactic latitude patch of sky in the northern hemisphere, and observed for 10 straight days. The result was the deepest optical image of the sky yet obtained: The Hubble Deep Field (HDF) (henceforth referred to as the Hubble Deep Field North, or HDF-N). The images allow detection of sources as faint as V = 30 in four bandpasses spanning the near-UV to the near-IR (Williams et al. 1996). The data were released to the community within one month of the observations and have been used in a wide variety of projects and publications, ranging from studies of the star-formation rate as a function of redshift, to studies of faint M dwarfs in the Galactic halo.

A second Hubble Deep Field campaign was carried out between late September and October of 1998. The raw, pipeline calibrated and reprocessed data were released to the community on November 23, 1998. The rationale for undertaking a second deep field campaign followed from the wealth of information that has come out of HDF-N, and from the desire to provide a point of focus for similar studies of the distant universe from southern-hemisphere facilities. The wide public access to the HDF-N data stimulated extensive followup observations across the electromagnetic spectrum, both from major ground-based observatories and from other satellites. A similar level of effort is anticipated for HDF-S. We are maintaining a `clearinghouse' for supporting and follow-up observations of the HDF-S.

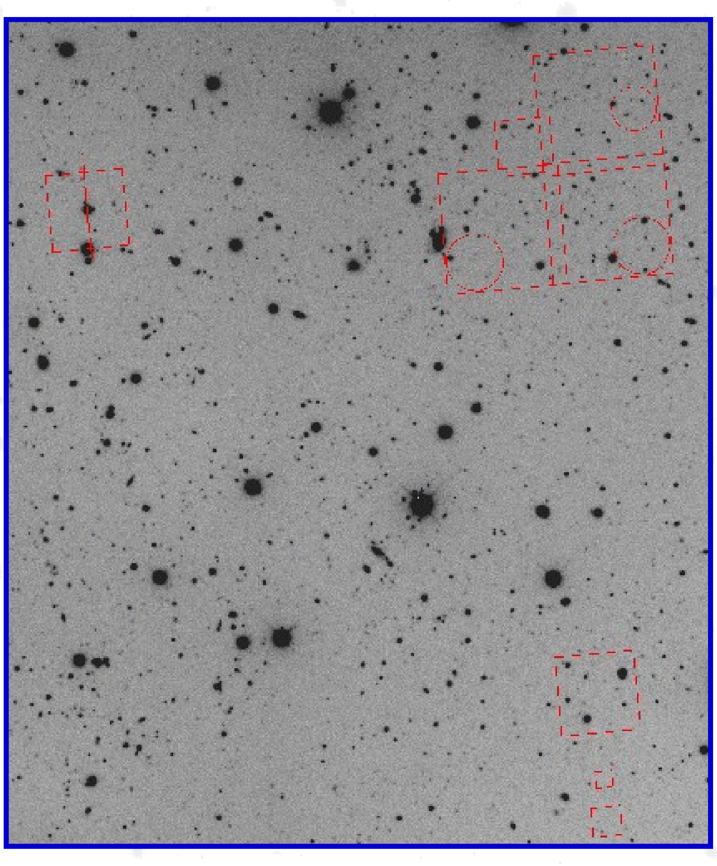
Test observations of the HDF-S field were obtained in October, 1997. The primary purpose of the test was to ensure that the guide stars to be used for the full campaign were acceptable, but an initial reconnaissance of the field was also carried out.

The HDF-S campaign differs from the HDF-N campaign in several important areas:

- The field is located in the *Southern* Continuous Viewing Zone. Choice of a field in the CVZ maximizes the observing efficiency of HST. The J2000 coordinates of the HDF-S are given here).
- A moderate redshift quasar of z ~ 2.24, identified by Boyle, Hewett, Weymann and colleagues, was placed in the STIS field for both imaging and spectroscopy so that correlations between quasar absorption redshifts and the redshifts of galaxies in the fields may be determined. Information on the QSO can be found in papers by Sealey et al. (1998) and by Savaglio (1998).
- Simultaneous, parallel observations were made with the three HST instruments STIS, WFPC2 and NICMOS of separate, neighboring fields. The STIS and NICMOS observations are significant enhancements over what was possible during the HDF-N campaign (although the HDF-N was later observed with NICMOS by GTO and GO teams).
- The early planning of the HDF-S allowed several preparatory studies to be carried out in advance, as collected on the HDF-S Clearinghouse web page.

The actual observations of the HDF-S were similar in spirit to the original HDF. As was the case for HDF-N, approximately 150 consecutive orbits were devoted to a single telescope pointing. Additional flanking field observations were made surrounding the deep STIS, WFPC2 and NICMOS fields.

Layout Main Fields

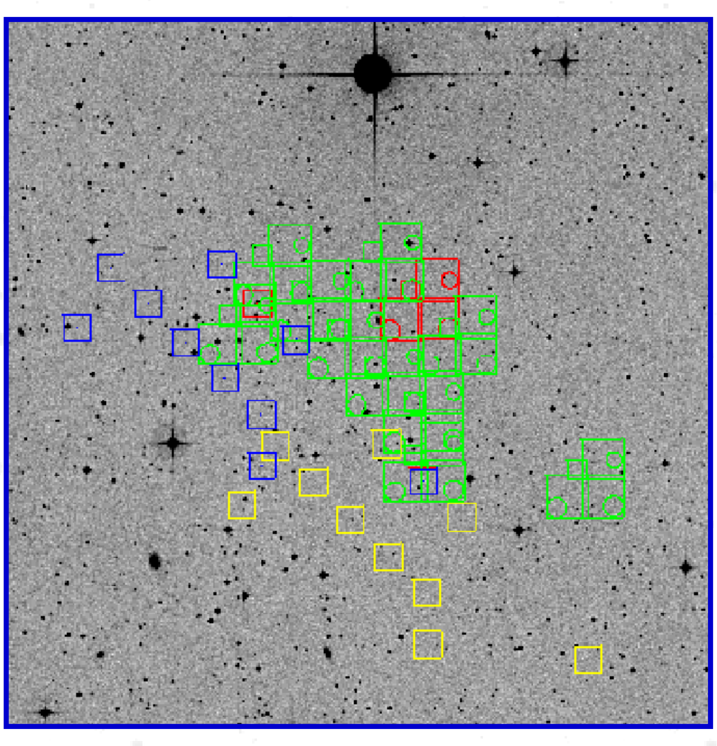


The figure shows the position of the HDF-S overlayed on a deep ground-based image. The image is a 3000s R-band exposure from the CTIO 4m telescope (courtesy of Alistair Walker). North is up and East is left. The WFPC2 region is to the West, the STIS region is to the East and NICMOS region is to the South. The STIS field is centered on the quasar at z ~ 2.24.

Note that the figure is for illustrative purposes only. The overlaid positions of the STIS and WFPC2 fields are accurate only to a few arcsec. The overlaid positions of the NICMOS fields are accurate only at the ~ 10 arcsec level. Use the calibrated J2000 coordinates of the HDF-S) when higher accuracy overlays are required.

Click on the image to get a larger scale view of the field.

Layout Flanking Fields



As with the HDF-N, some time during the HDF-S campaign was devoted to obtaining WFPC2 single-band images of a larger, contiguous area around the primary imaging field (the "flanking fields"), to a typical depth of I_AB ~ 25.5. The current plan is to observe a region about 7 arcmin in diameter, defined so as to include both the STIS and the NICMOS primary target regions. The goals of the wide-area imaging are to provide a large contiguous area for angular correlation studies, especially interesting near the QSO; to yield better statistics for less numerous, brighter galaxies; and to provide optical morphologies for galaxies in the larger fields typical of ground-based multi-object spectrographs.

The figure shows the tentative HDF-S flanking field arrangement as laid out several months before the campaign, overlaid on an image extracted from the Digitized Sky Survey. Note that the figure is for illustrative purposes only. The arrangement used for the actual campaign may have been slightly different, due to late changes in the observing strategy. Consult the actual Observing logs or the header information of the data files for more detailed information.

The red field is the main HDF-S WFPC2 field. The green fields are flanking fields for the WFPC2 with the F814W filter. The blue fields are the STIS CCD fields associated with the flanking fields, and the yellow are flanking-fields for the NIC3 parallels with the F160W filter. The main NIC3 field was observed for 9 orbits with the STIS CCD (no filter). The right-most WFPC2 flanking field is the parallel frame associated with that exposure.

Click on the image to get an overlay of the same flanking field arrangement on the deeper R-band ground-based CTIO image.

Observing strategy

Discussions about the observing strategy for the HDF-S focussed primarily on the questions:

- What filters/gratings to use for each instrument ?
- What exposure time to use for each filter/grating ?
- How to choose the detailed instrumental setup and observing parameters ?
- How to pack the observations into the individual orbits during the campaign ? In CVZ observations, scattered earth light increases the sky background in certain bandpasses on the day side of the orbit. It was therefore essential to tailor the observations for all the instruments to make optimal use of `bright' and `dark' time.

A detailed but outdated discussion of the observing strategy for each of the individual instruments is available:

- WFPC2
- NICMOS
- STIS

These discussions describe various general issues, as well as the planned observing strategy as of July 1998. The strategy used for the actual campaign was somewhat different, due to late changes in the observing strategy. Consult the actual Observing logs or the header information of the data files for more accurate and up-to-date information on the observing strategy.

Warnings and Advisories

Information is available for the following topics:

- General
- STIS Spectroscopy
- STIS Imaging
- WFPC2
- NICMOS
- Flanking Fields

General

[2] (11/29/98) When browsing through this web site, always use **RELOAD** on your browser to make sure you get the latest version of a page, rather than an older version that still exists in the cache.

[1] (11/23/98) The headers of the files may be lengthy. To avoid IRAF errors associated with the headers being too long, include the following in your login.cl: **set min_lenuserarea = 500000**

STIS Spectroscopy

[2] (11/24/98) In the Version-1 data (11/23/98) there was an error in the G230L wavelength scale, introduced in the last step of the data reduction. This was corrected in version 1b, released December 21, 1998.

[1] (11/23/98) In the Version-1 data (11/23/98) there is a mismatch between the fluxes of the G430M spectrum and the G230L and E230M spectra in the wavelength region from 3000 to 3200 Angstroms. This discrepancy is under investigation. In the meantime, caveat emptor.

STIS Imaging

[1] (11/23/98) Please read the section on the window reflection before trying to identify or analyze objects close to the quasar!

WFPC2

NICMOS

[3] (11/24/98) Photometric zeropoints : There remains some significant uncertainty in the absolute photometric calibration of the NICMOS HDF-South images, with zeropoints for some bands uncertain at roughly the 10% level. Please read the discussion of NICMOS photometric zeropoints for further information. USERS WHO REQUIRE ABSOLUTE PHOTOMETRY BETTER THAN 10% IN THE NICMOS DATA SHOULD PROCEED WITH CAUTION BECAUSE OF THESE UNCERTAINTIES. We will provide updated information on photometric zeropoints on these web pages as it becomes available.

[2] (11/24/98) PSF distortion : The tilted Field Offset Mirror (FOM) position used for the NICMOS HDF-South imaging results in some distortion of the point spread function over the field of view. Caution should be exercised in any analysis requiring precise information about the PSF.

[1] (11/24/98) Linearity corrections : During the course of HDF-South data reduction we identified problems with the standard procedures used to correct nonlinearity in NICMOS images. A new procedure was implemented for the F222M images (where the high thermal background countrate makes linearity correction necessary) but has not yet been applied to the F110W and F160W images. Moreover the new procedure is based on a preliminary revision to the linearity calibrations and has not yet been fully tested. It is unlikely that these linearity corrections affect object photometry by more than a few percent, i.e. the resulting uncertainties are probably smaller than those of the absolute photometric zeropoints of the data (see above). We will be investigating this in more detail in the near future.

Flanking Fields

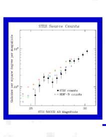
[2] (12/21/98) The final reprocessed data for all the **WFPC2 Flanking Field observations** are now available. This includes the positions 1-9, as well as the longer, 9 orbit, observations taken in parallel with STIS observations of the NICMOS deep field.

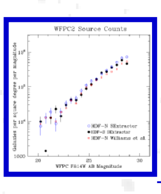
[1] (11/23/98) The **NICMOS Flanking Field data** are still being processed. The final data products will be made available as soon as they are finished. Our current target date is mid-January 1999. Raw and calibrated data for individual datasets are already available from the HST Data Archive.

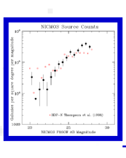
This page was last updated on December 23, 1998.

Source Catalogs

Catalogs of sources found in the HDF-S images can be obtained from this page.





HDF-S STIS catalog | HDF-S WFPC2 catalog | HDF-S NICMOS catalog

HDF-N WFPC2 catalog

HDF-S WFPC2 catalog version 2

The version 1 catalogs were produced using the Source Extractor (SExtractor) package. Details of the parameters used to control the source detection and photometry are given in the README files found with the catalogs.

Detection of faint sources near brighter objects poses a difficult problem for automated photomtetry programs. SExtractor fares better than most, but nevertheless no single set of deblending thresholds, cleaning parameters, etc., was deemed acceptable. In particular, the set of parameters that did the best job for detecting the typical faint, relatively isolated galaxies, would tend to over-merge galaxies near bright stars (counting them as part of the star rather than keeping them as separate objects). While this has a negligible effect on faint-galaxy statistics, it did produce a catalog that did not have separate entries for a number of objects that might be good candidates for spectroscopy. To recover these objects, SExtractor was run multiple times with different detection thresholds. Objects that were considered to be "over merged" in the first catalog were deleted from that catalog and the entries for their various subcomponents were taken from a catalog with a higher detection threshold. A few obvious artifacts due to diffraction spikes were deleted from each catalog as well. The object numbering and the IMA_FLAGS parameter indicate which SExtractor run each catalog entry came from. The number of objects added and deleted for the different catalogs were WFPC2: 24 deleted, 31 added; STIS: 26 deleted, 8 added; and NICMOS: 14 deleted, 29 added.

The WFPC-2 catalog of HDF-N published by Williams et al. (1996) used a modified version of FOCAS for source detection and photometry. To aid in comparison to HDF-S, we have constructed a SExtractor catalog of HDF-N.

Technical information on the construction of the catalogs for the individual instruments is available:

- STIS
- WFPC2
- NICMOS
- HDF-North

The Hubble Deep Field South

NEW This list was updated on March 5, 1999, and replaces the list that was posted on this page from November 23, 1998 to March 4, 1999. Contact Sandra Savaglio for details about the improvements in the new list.

Absorption Line List for the QSO J2233-606 sight-line

The MIDAS package FITLYMAN (Fontana & Ballester, The ESO Messenger, 80, 37 1995) has been used to measure the parameters of absorption lines in the full range (interval 2350 A - 4330 A) of the spectra E230M, G430M of STIS/HST and of the spectrum UCLES/AAT (Outram et al., 1998, MNRAS submitted, astro-ph/9809404). Line fitting through chi^2 minimization of Voigt profiles provides the redshift, the Doppler parameter b, the column density and the Equivalent Width. Multiple lines of a single ion have been fitted simultaneously. The line identification should be considered preliminary and line parameters taken with caution due to the considerable uncertainties. About 257 Lyman-alpha clouds have been identified in the redshift range 1.201 - 2.247, though a small fraction of them might be misinterpreted unidentified metal lines.

Coordinates

For accurate information on coordinates and astrometry of the HDF-S check the header information in the final data products. Consult the technical information on the data reduction to assess the accuracy of the header coordinates systems.

The following coordinates may be useful, but please contact us for up-to-date details if you plan supporting observations of this field.

WFPC2 (apex) pointing

```
22h 32m 56.22s      -60d 33' 02.69"    J2000 Equinox
```

Note: PA_V3 = 230.5D, which corresponds to U3 ORIENT=50.5D.

STIS pointing

```
22h 33m 37.67s      -60d 33' 28.95"    J2000 Equinox
```

The position of the QSO has been determined with estimated errors less than 40 milli-arcseconds to be:

```
22h 33m 37.5883s    -60d 33' 29.128"   J2000 Equinox
```

NICMOS (NIC3) pointing

```
22h 32m 51.75s      -60d 38' 48.20"    J2000 Equinox
```

Note: NIC3 coordinates are uncertain by about 5 arcsec.

Observing Strategy

Discussions about the observing strategy for the HDF-S focussed primarily on the questions:

- What filters/gratings to use for each instrument ?
- What exposure time to use for each filter/grating ?
- How to choose the detailed instrumental setup and observing parameters ?
- How to pack the observations into the individual orbits during the campaign ? In CVZ observations, scattered earth light increases the sky background in certain bandpasses on the day side of the orbit. It was therefore essential to tailor the observations for all the instruments to make optimal use of `bright' and `dark' time.

Below please find discussions of the observing strategy for each of the individual instruments. For more detailed information, check the instrument specific technical pages for a description of the data products and the implemented data reduction steps for STIS , WFPC2 , NICMOS and the Flanking Fields . Consult the observing logs or the header information of the data files for additional information. Check the page with warnings and advisories before making any use of the data.

WFPC2

The WFPC2 observing strategy was similar to that for HDF-N. We used the same filters, F300W, F450W, F606W, and F814W, and very similar total observing times. During each orbit, the part with elevated background (because of scattered Earth light) was used for F300W, where the background accounts for a relatively small fraction of the total noise. The remaining time was split evenly between F450W, F606W and F814W, with F606W receiving somewhat less observing time than the others.

Different areas of the Version 1 output image correspond to variable amounts of exposure time, due to the relatively large pointing shifts necessitated by the multi-instrument observing strategy. The weight images delivered with each image can be used to estimate the noise per unit area in the output images. About 7% of the individual exposures were excluded from the Version 1 images, generally because more processing was necessary either to determine an accurate pointing or to correct some minor image blemishes.

For quick estimates of the image depth, these are the average exposure times used in the Version 1 images and an approximate limiting magnitude for each filter (defined as 10-sigma within a 0.2 square arcsec area, or 125 pixels in the processed image):

Table 1. WFPC-2 Filters, exposure times and limiting AB magnitudes for Version 1 images

Filter	Exposure time (ks)	AB mag. limit S/N=10 in 0.2 sq. arcsec
F300W	140	26.8
F450W	101	27.7
F606W	81	28.2
F814W	100	27.7

NICMOS

The discussion of the observing strategy for NICMOS given here is **somewhat outdated**. It describes general issues, as well as the planned strategy as of **July 1998**. The strategy used for the actual campaign was somewhat different, due to late changes in the observing strategy. Consult the observing logs or the header information of the data files for more accurate information.

NICMOS will observe in parallel with WFPC2 and STIS, with the Pupil Alignment Mechanism (PAM) set to optimize focus for Camera 3, providing the widest available field of view. At present and in the foreseeable future, Camera 3 remains somewhat out of focus even with the PAM set to the end of its travel range. Nevertheless, the image quality is sharp enough to be undersampled by the NIC3 pixels, and there is little doubt that interesting science on faint galaxy images can be achieved. The images will be dithered using the NICMOS Field Offset Mirror (FOM) in order to improve flat fielding, sky subtraction, and detector artifact removal.

Nearly all of the dark-time orbits will be used for broad band imaging with the F110W and F160W filters (J and H--bands, approximately), giving approximately 48 hours of observing in each band. Limiting magnitudes are given in Table 2. It appears that scattered earthlight during the ``bright'' portions of CVZ orbits affects NICMOS imaging, and various options (including K or narrow band imaging) are being considered to take advantage of these periods. Slitless grism spectroscopy is another option during dark time, but its utility may be compromised by the fact that we cannot easily obtain data at multiple position angles during the HDF-S campaign.

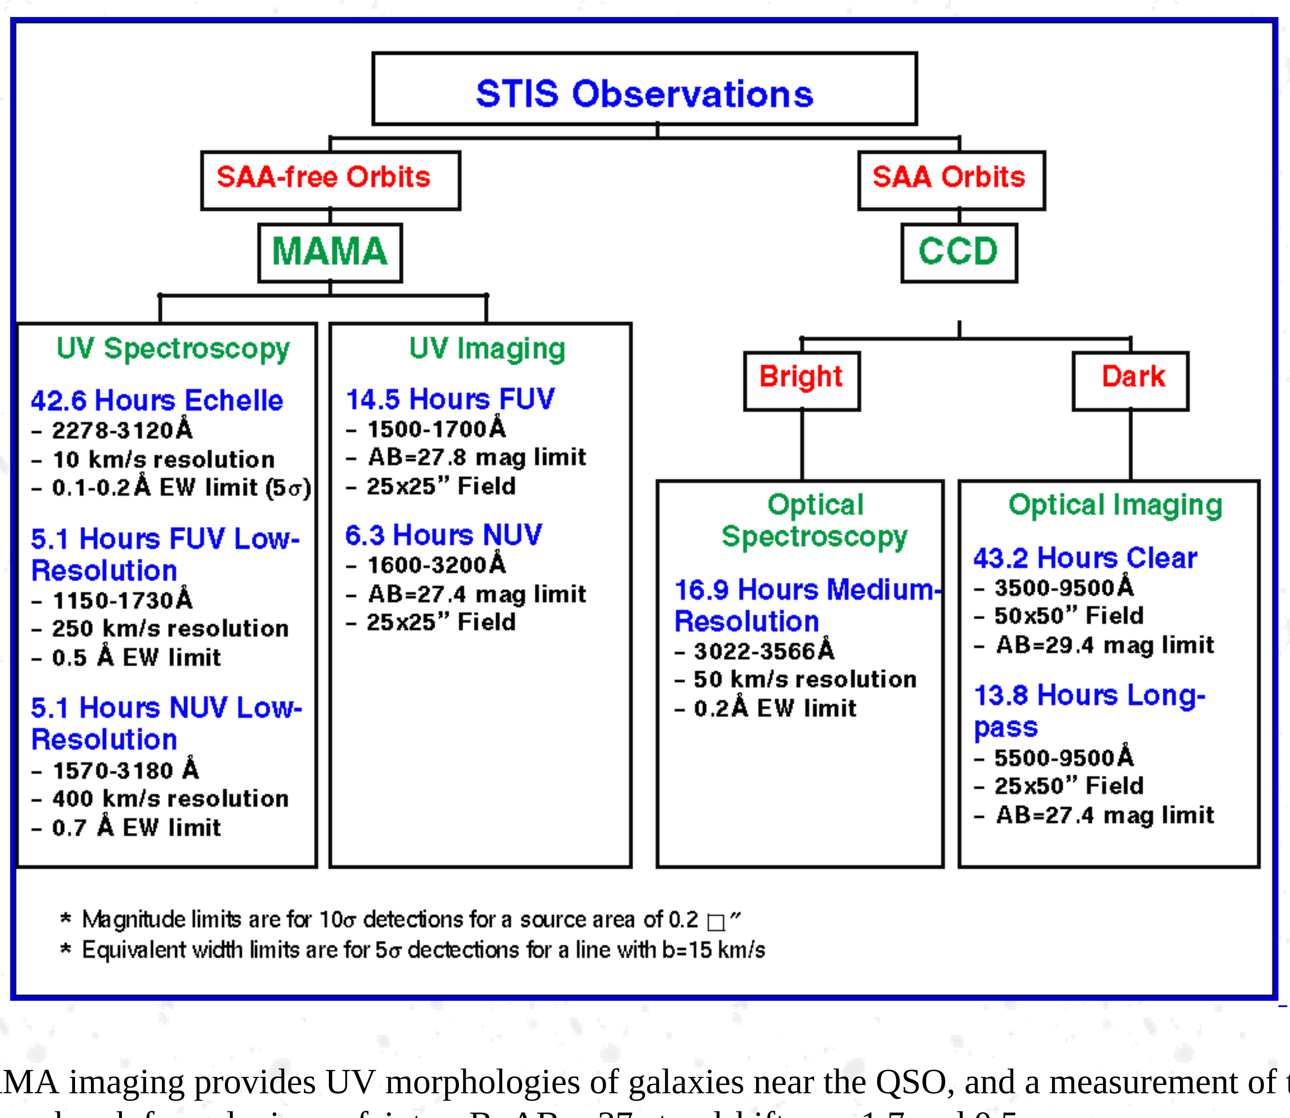
Table 2. NICMOS Filters, exposure times and limiting AB magnitudes

Filter	Exposure time (ks)	Surface Brightness limit (1 sigma over 1 sq. arcsec)	Limiting Magnitude S/N=10 in 0.8 sq. arcsec
F110W	176	6.4 x 10^-8 Jy/arcsec-2	J_AB = 27.0
F160W	174	7.6 x 10^-8 Jy/arcsec-2	H_AB = 26.8
F220M	111	1.0 x 10^-6 Jy/arcsec-2	K_AB = 24.0

STIS

Observations with the MAMA (UV) detectors on STIS are limited to about 60 orbits due to the restriction that they only operate during during SAA-free orbits.

The flowchart shows the STIS observing plan schematically. Most of the MAMA observing time is put into high-resolution spectroscopy. This provides high resolution (10 km/s) QSO absorption-line data in the region from 2650-3200 Angstroms, and low resolution (250 km/s) spectra from 1600 to 1200 Angstroms. The region from 1600-2650 is suppressed by a Lyman continuum absorption-line system at z ~ 1.9.



MAMA imaging provides UV morphologies of galaxies near the QSO, and a measurement of the Lyman break for galaxies as faint as B_AB = 27 at redshifts z ~ 1.7 and 0.5.

The STIS CCD images provide a deep view of galaxies immediately surrounding the QSO. The images are significantly deeper than those with the WFPC-2, and have a higher spatial resolution. Color information is a bit cruder than for the WFPC-2 images, but in the portion of the field with MAMA UV imaging and long-pass filter imaging, there are four bandpasses available for photometric redshifts, and the inclusion of the UV provides greater accuracy for galaxies in the redshift range 0.5-2.5.

Bright time for the CCD was used to obtain a QSO spectrum at a resolution of 30 km/s and with S/N ~50 per resolution element.

Table 3. STIS Modes and exposure times

Detector	Filter or Grating	Exposure time (s)
CCD	50CCD	155590
CCD	F28X50LP	49768
CCD	G430M (cenwave=3165)	31492
CCD	G430M (cenwave=3423)	25600
FUV-MAMA	G140L	18480
FUV-MAMA	MIRROR	52124
NUV-MAMA	E230M	151074
NUV-MAMA	G230L	18424
NUV-MAMA	MIRROR	22616

Phase 2 Proposal Information

For logistical reasons, the Hubble Deep Field South observations were split over 6 different proposals. Click below for the Phase 2 proposal information.

Main-field observations

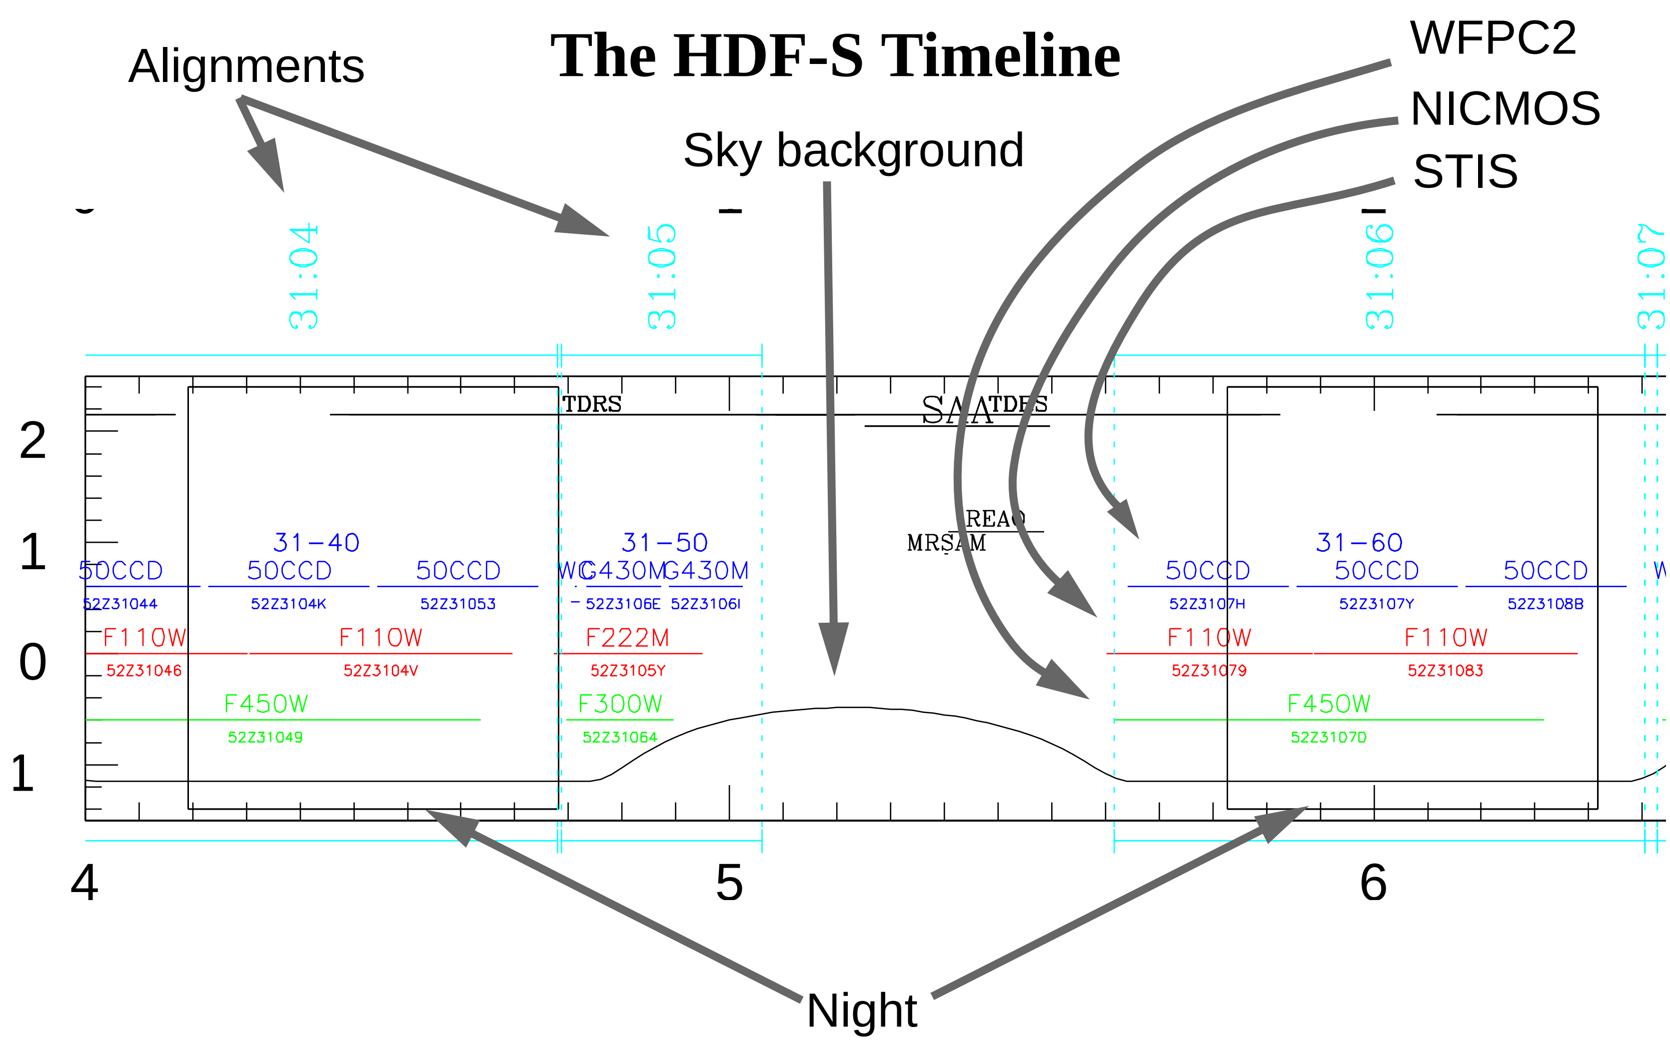
- Part 1: 8058
- Part 2: 8073
- Part 3: 8074
- Part 4: 8075
- Part 5: 8076

Flanking field and PSF star observations

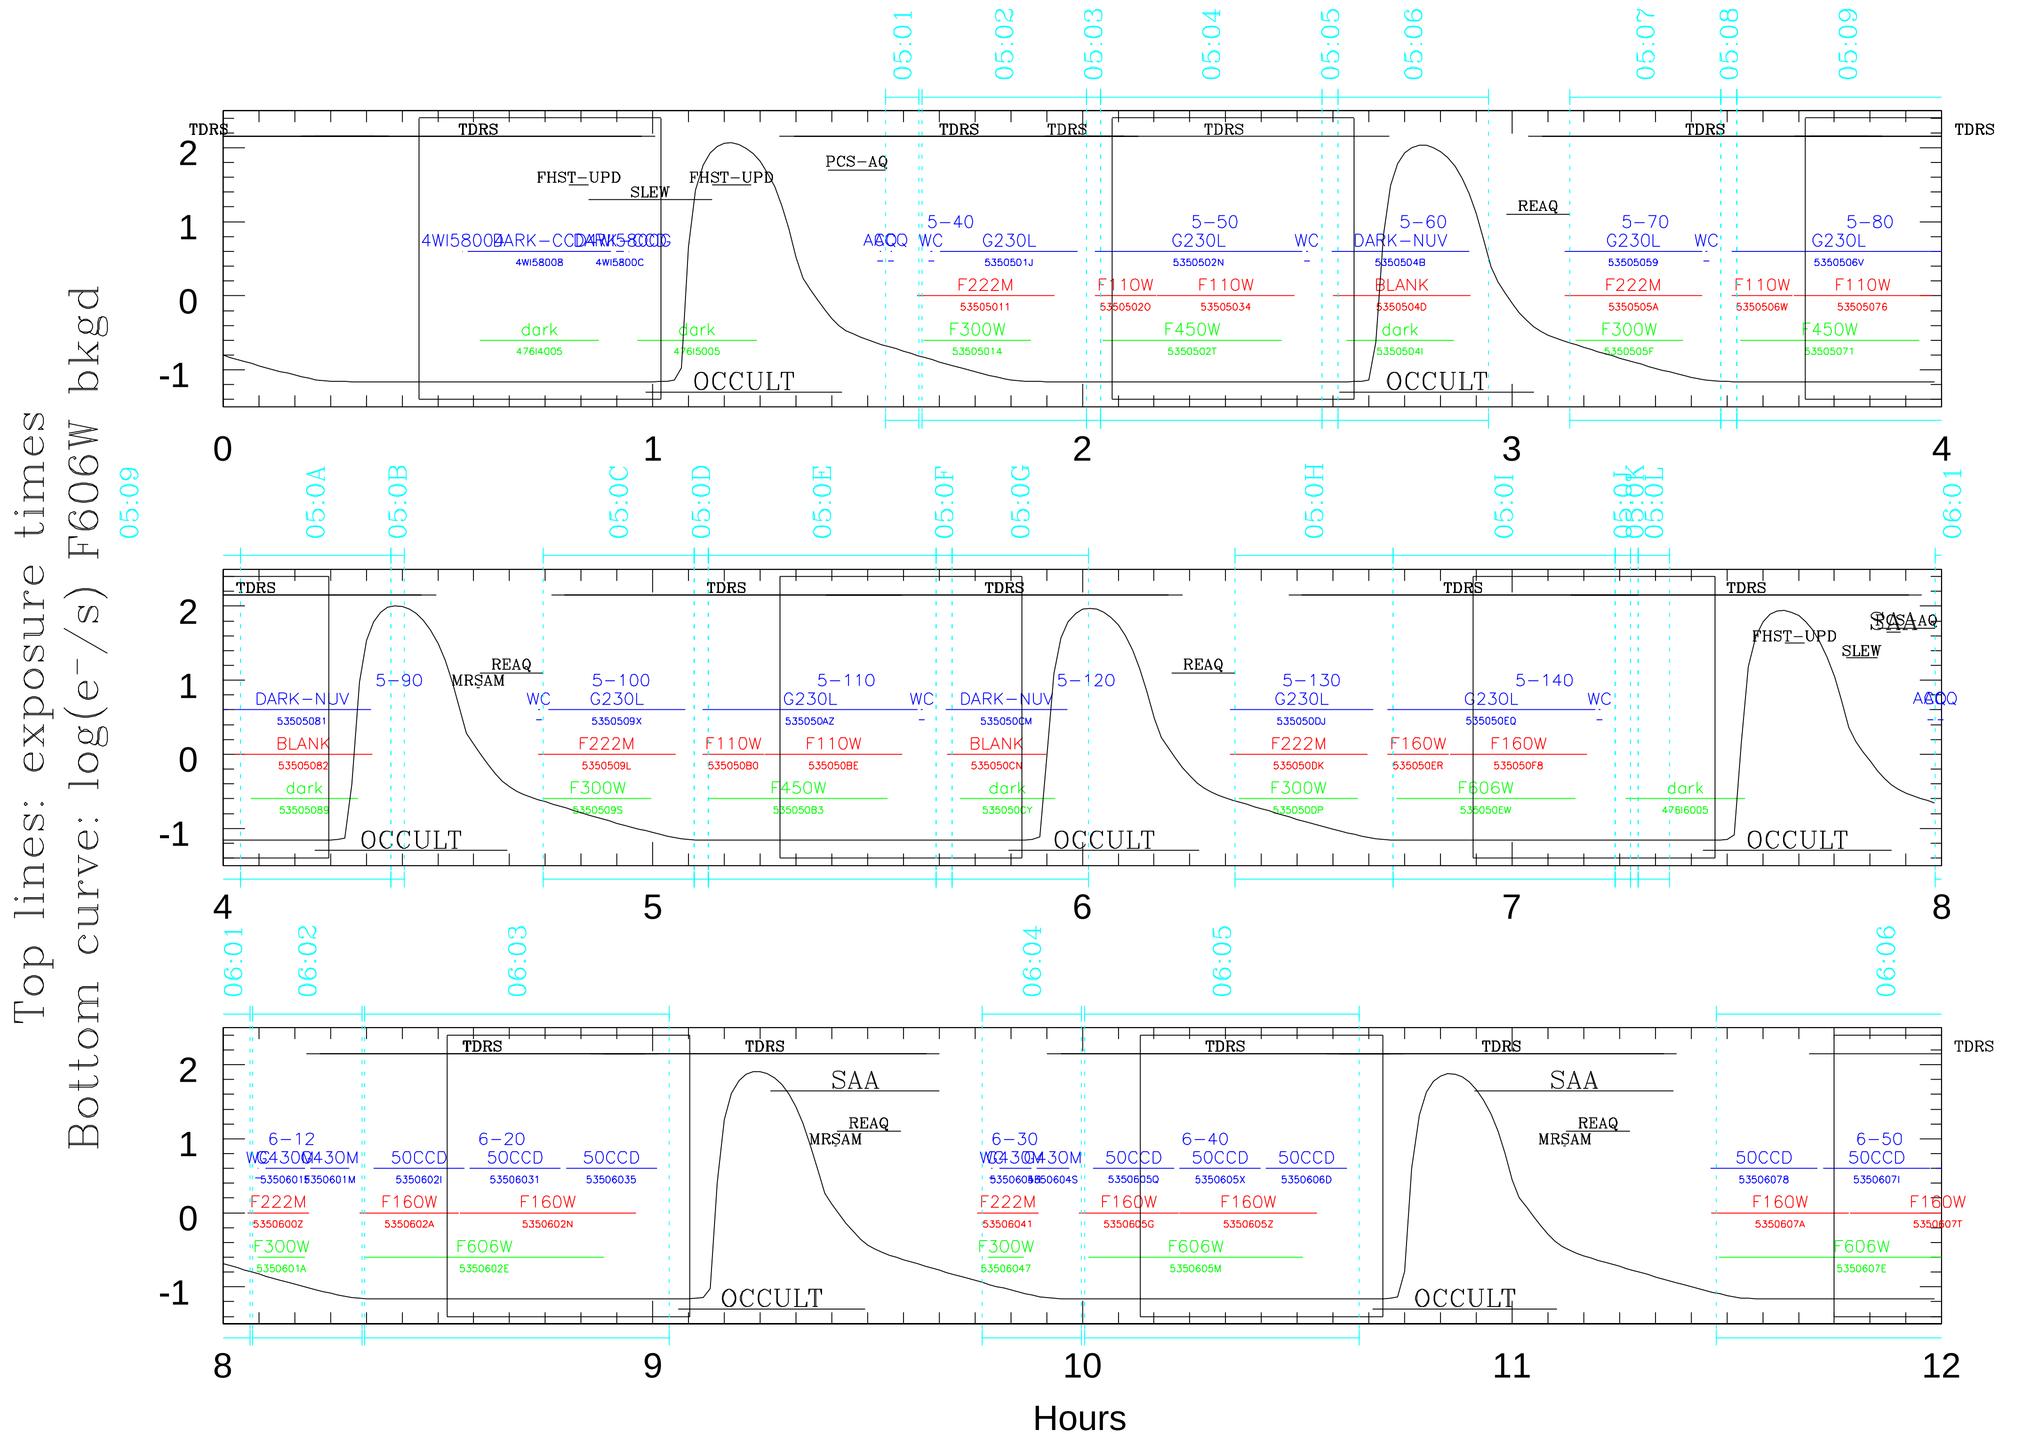
- 8071

This page was last updated on November 23, 1998.

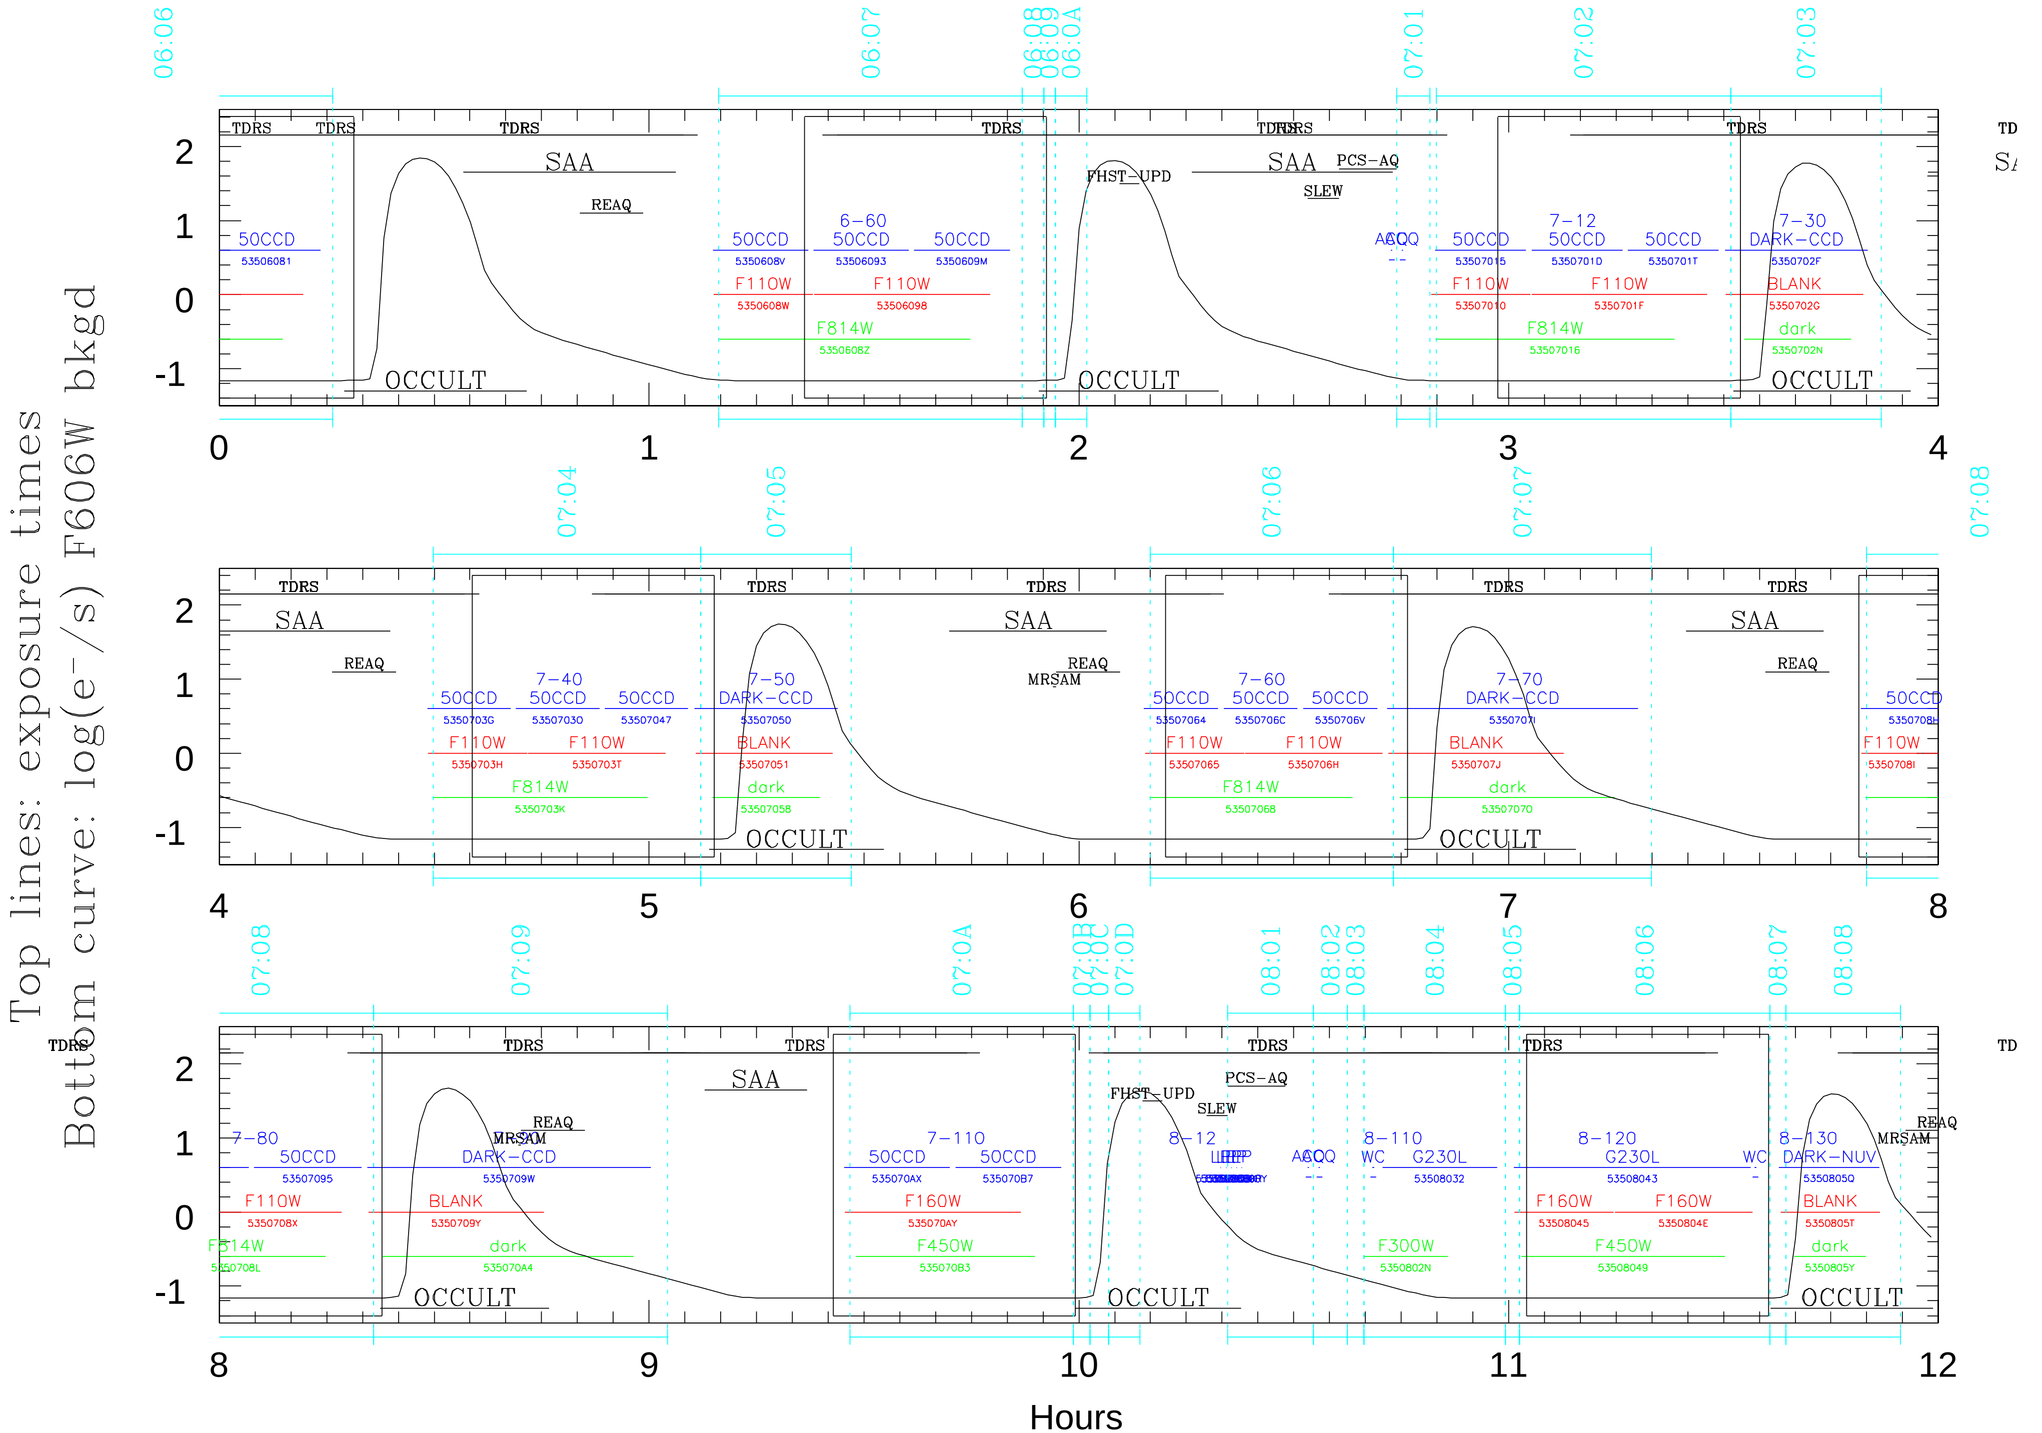
The HDF-S Timeline



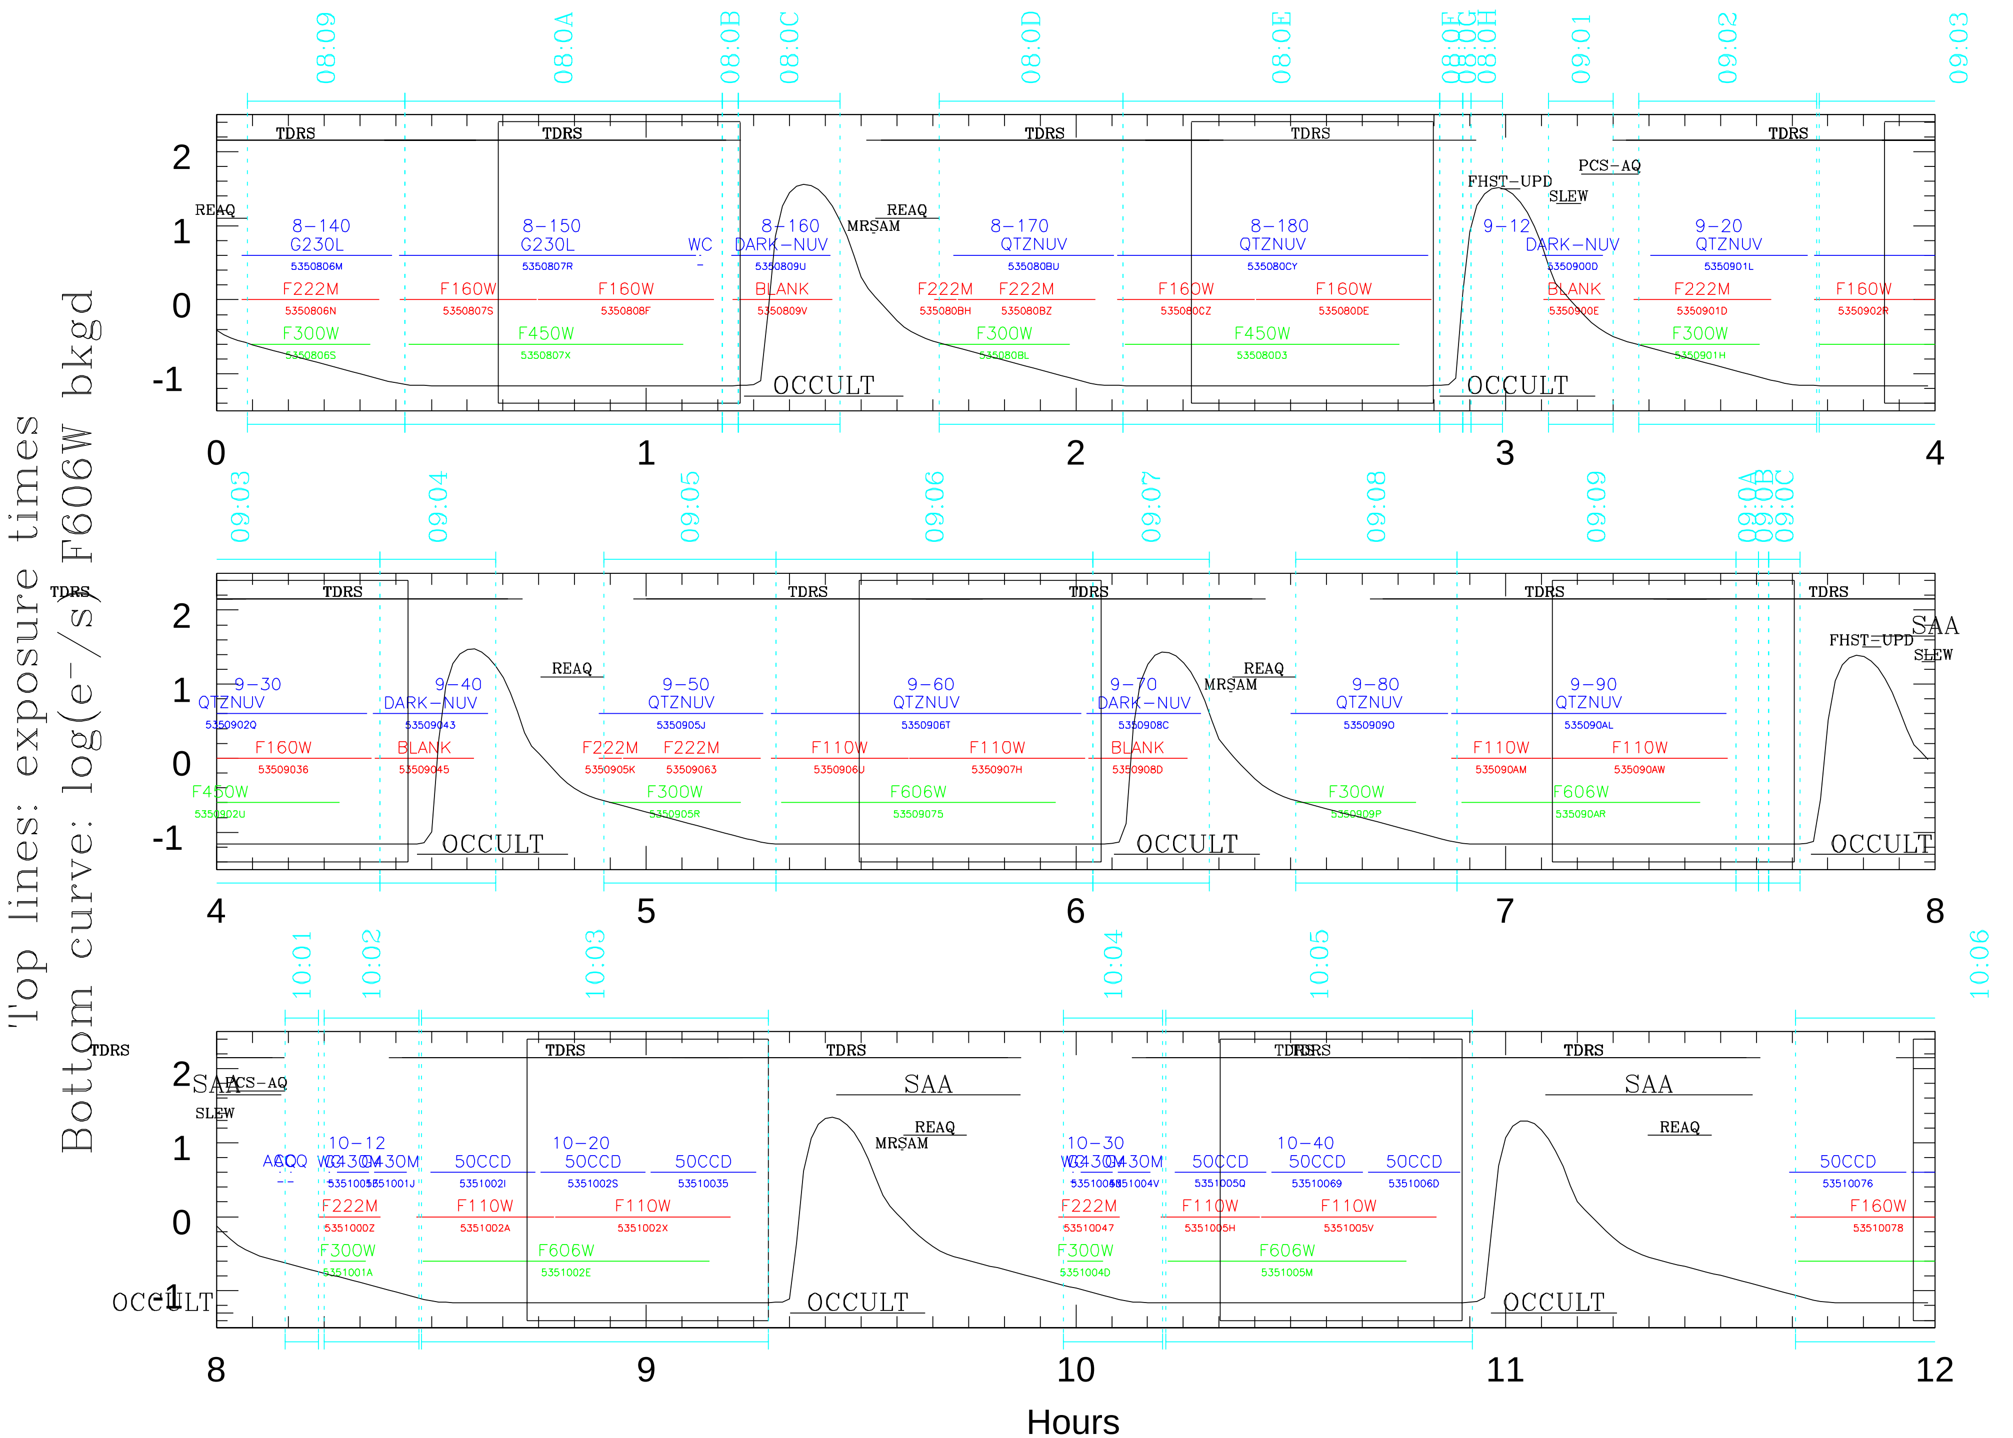
Day 271 = September 28



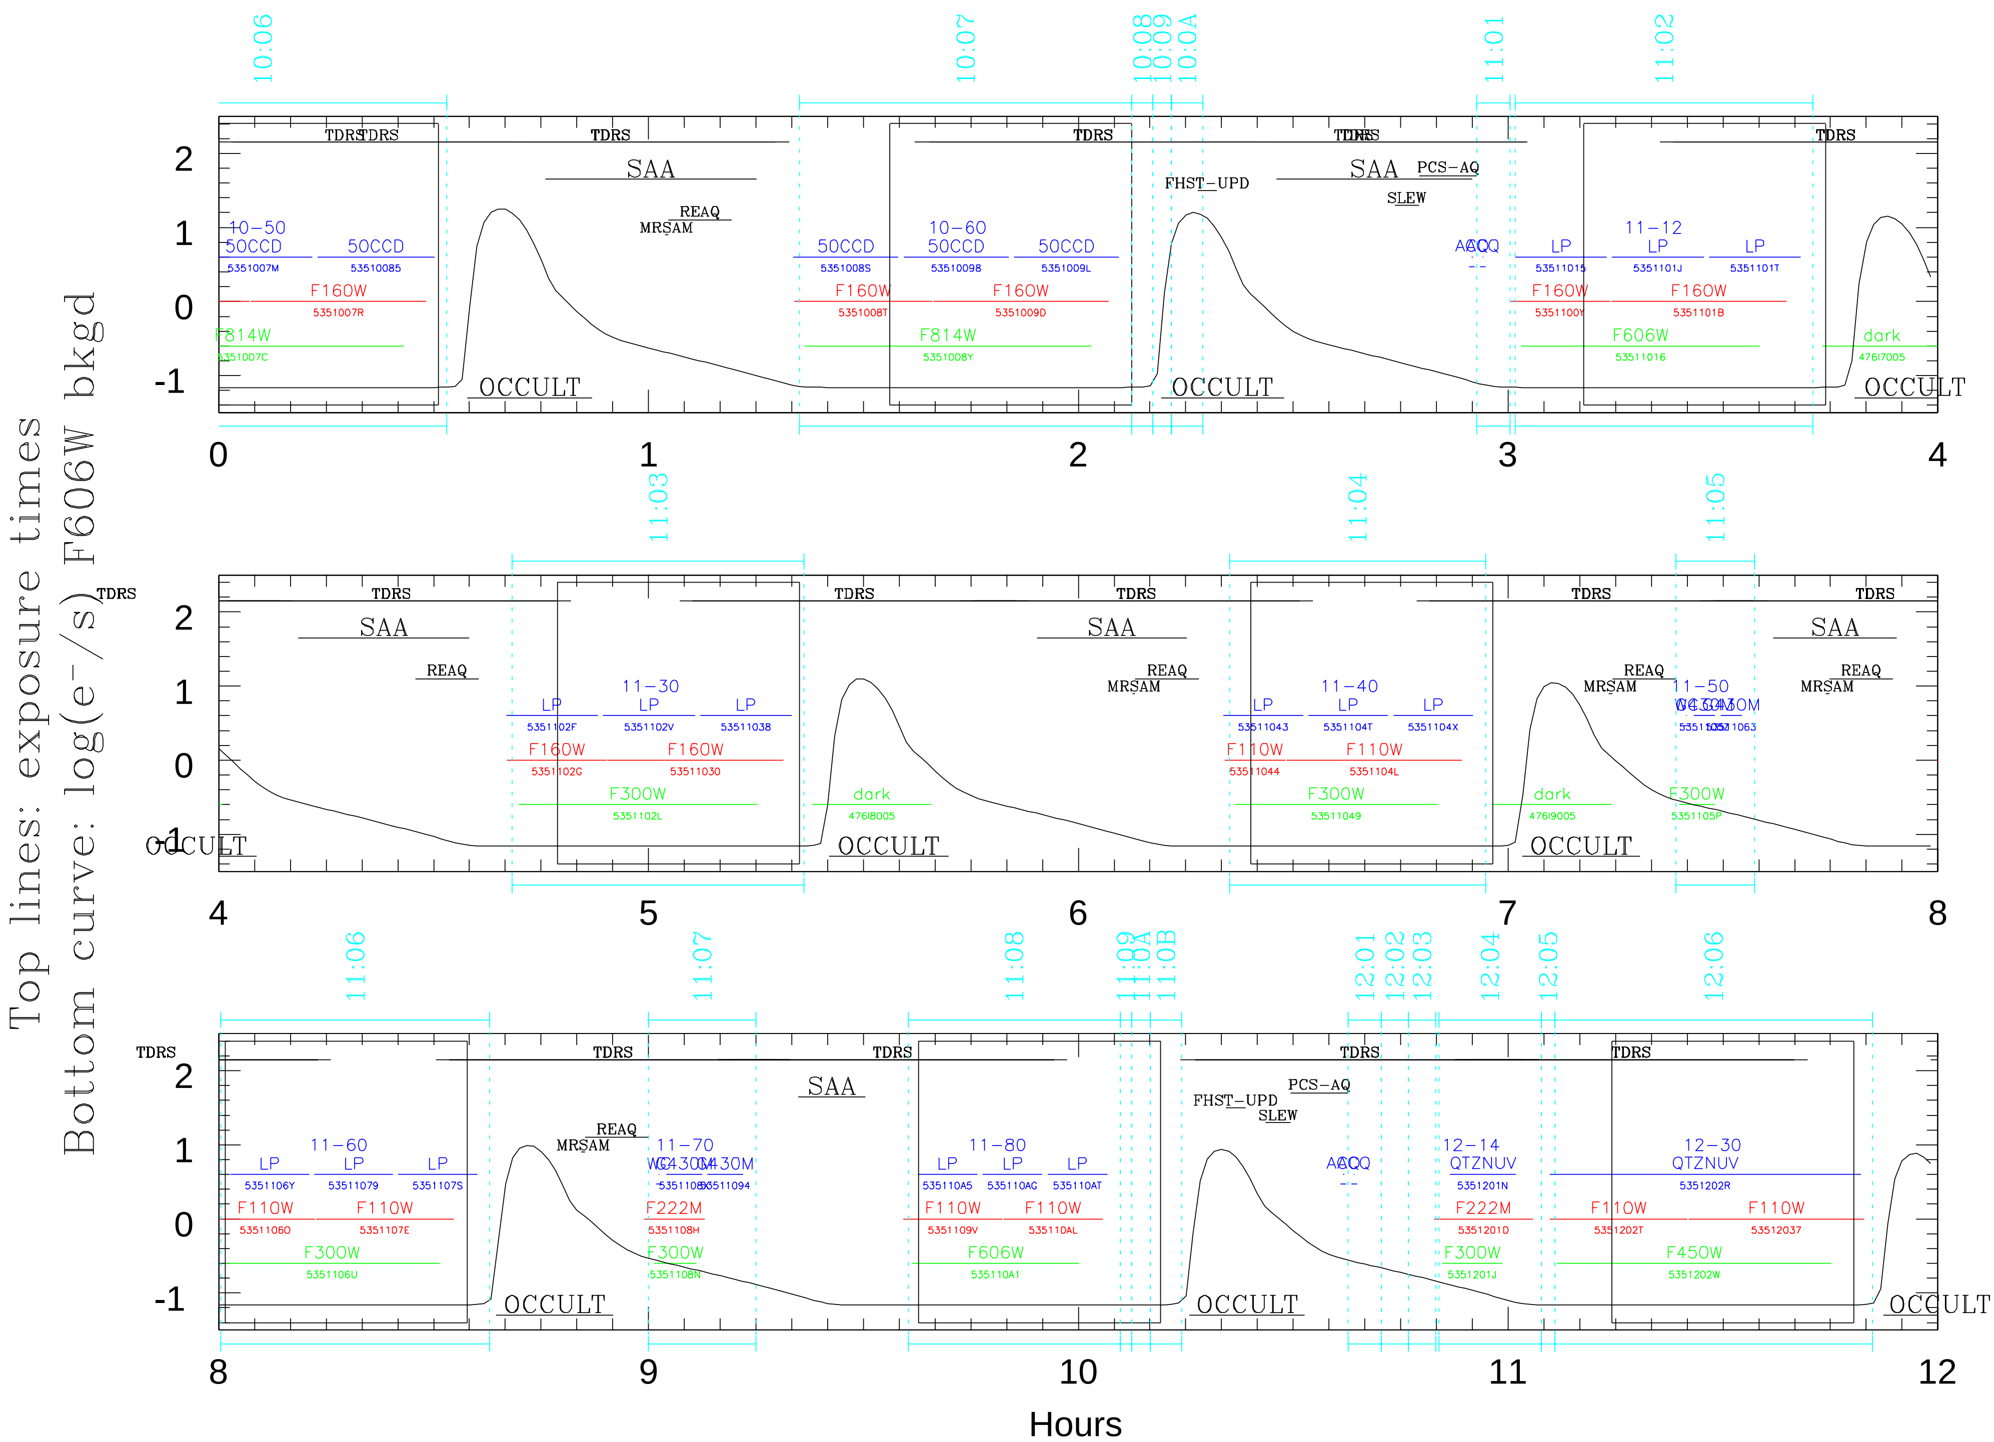
Day 271.5 = September 28



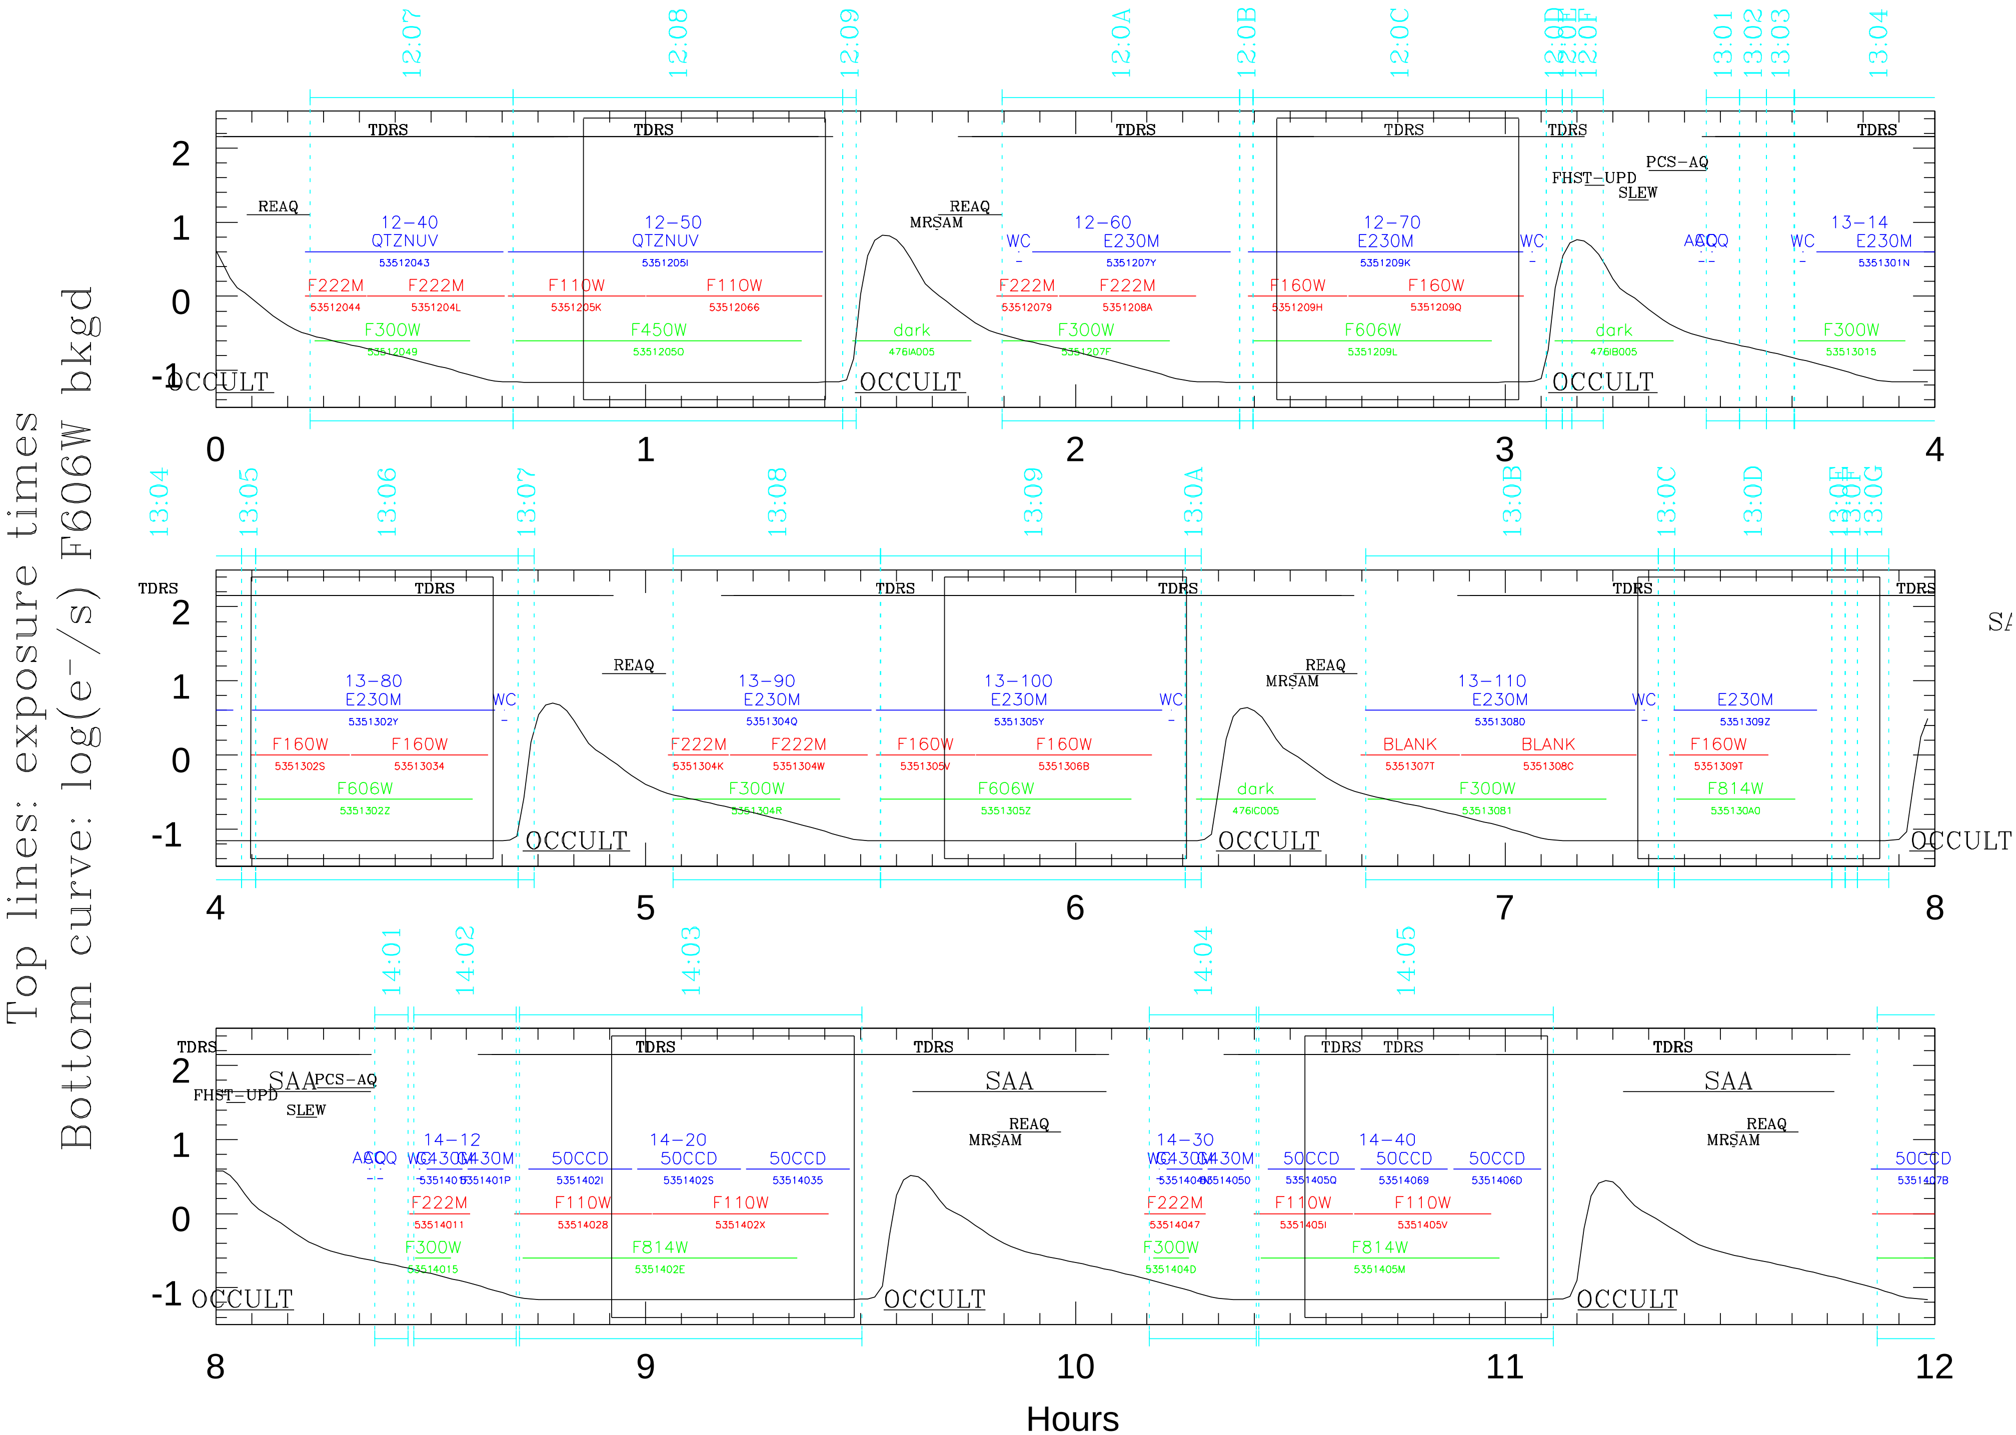
Day 272 = September 29



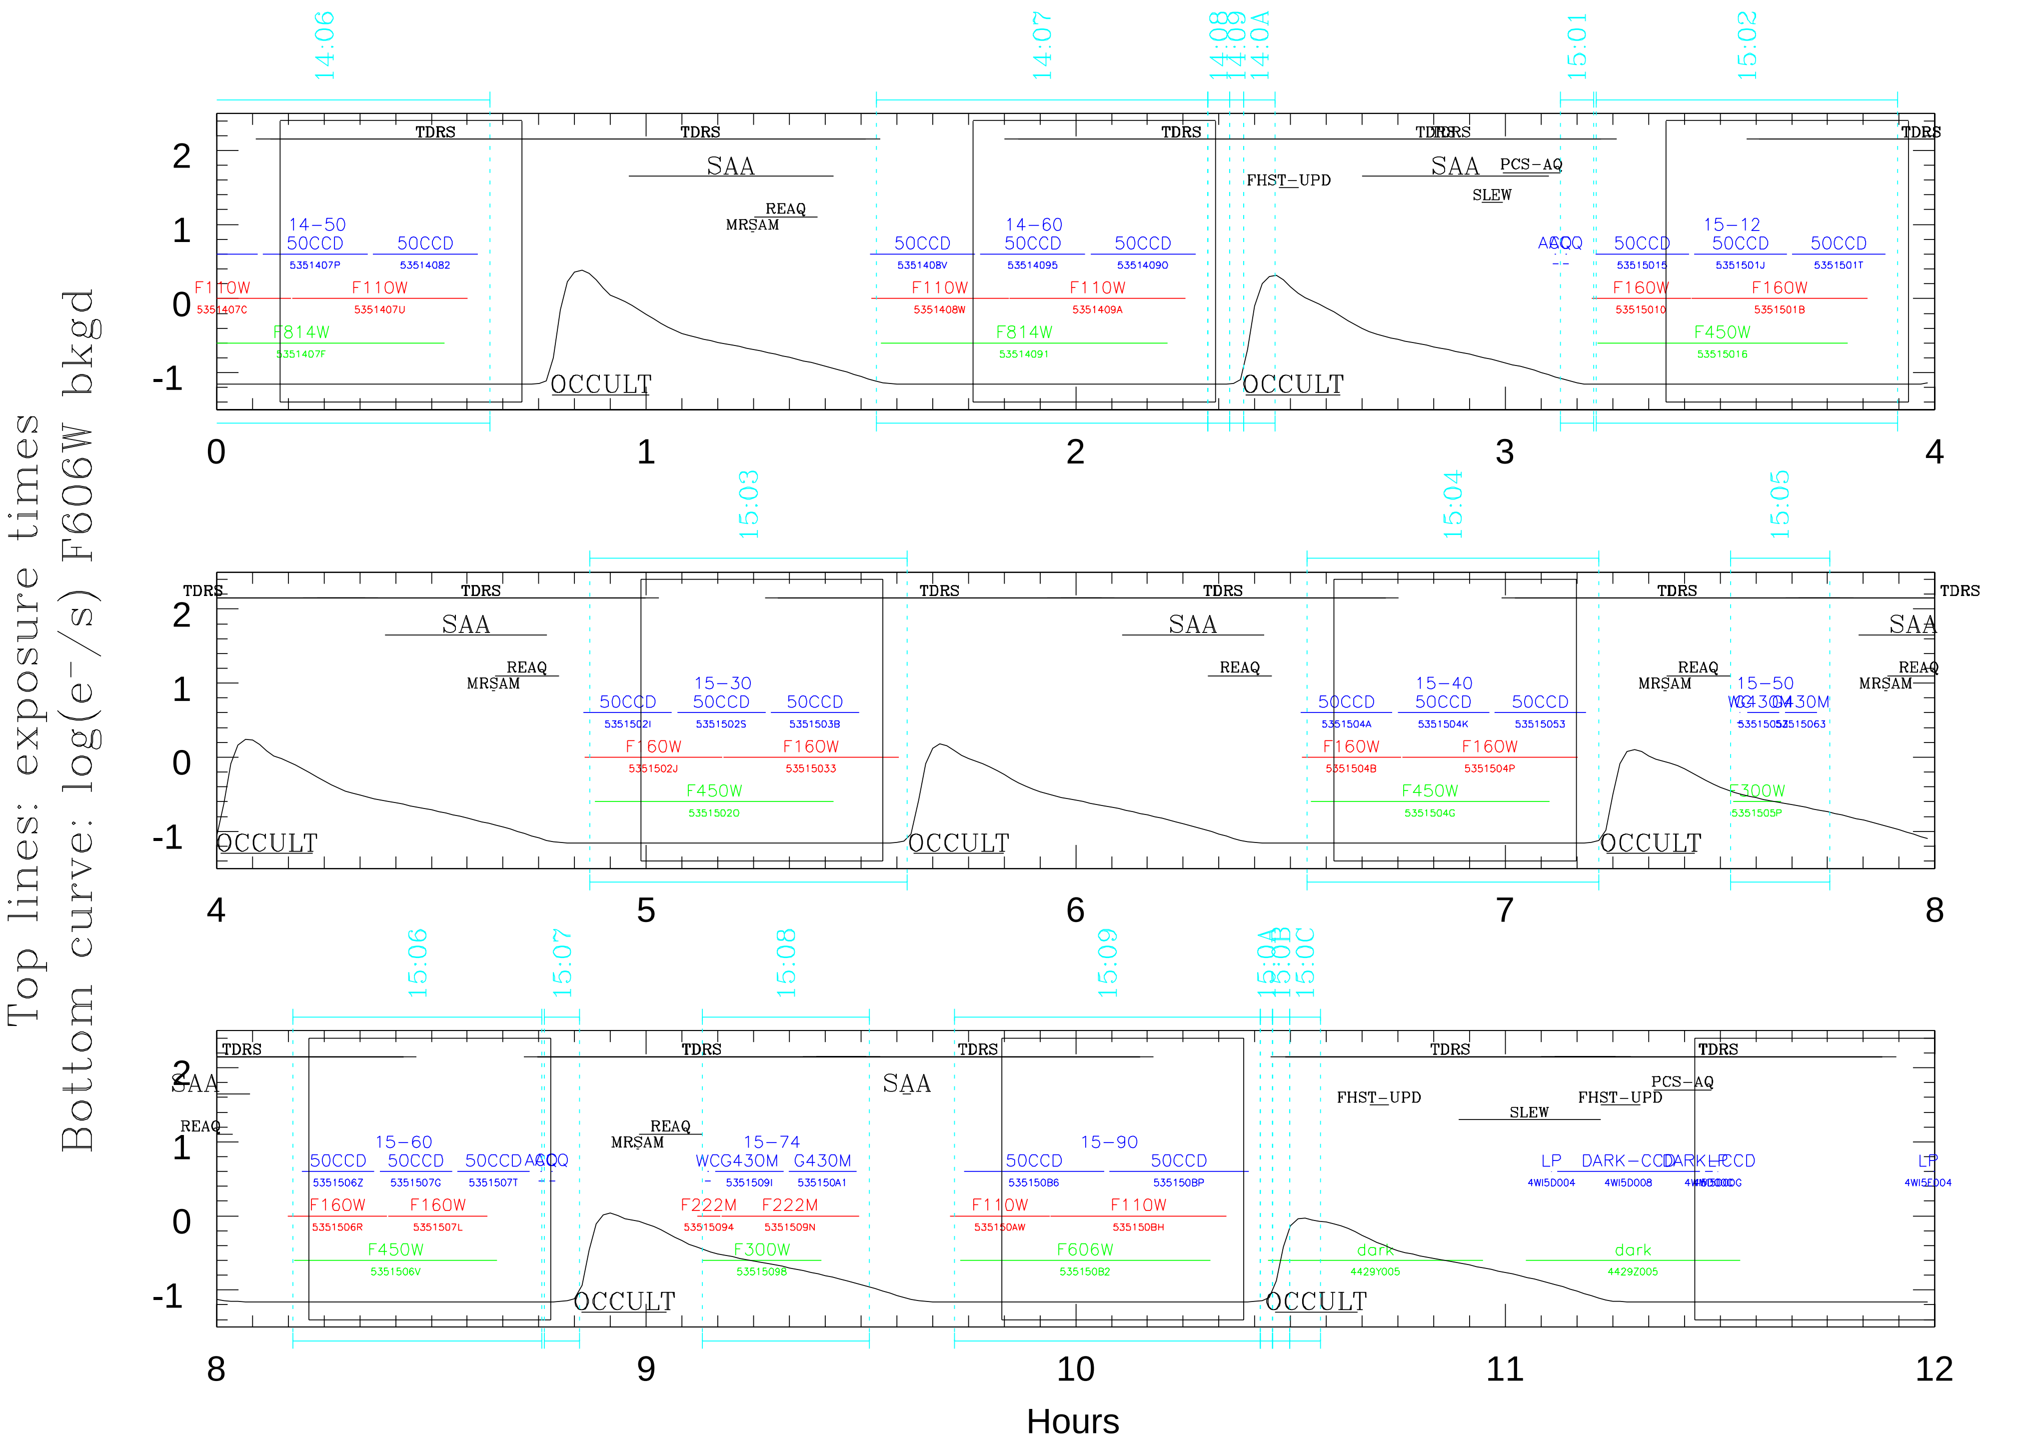
Day 272.5 = September 29



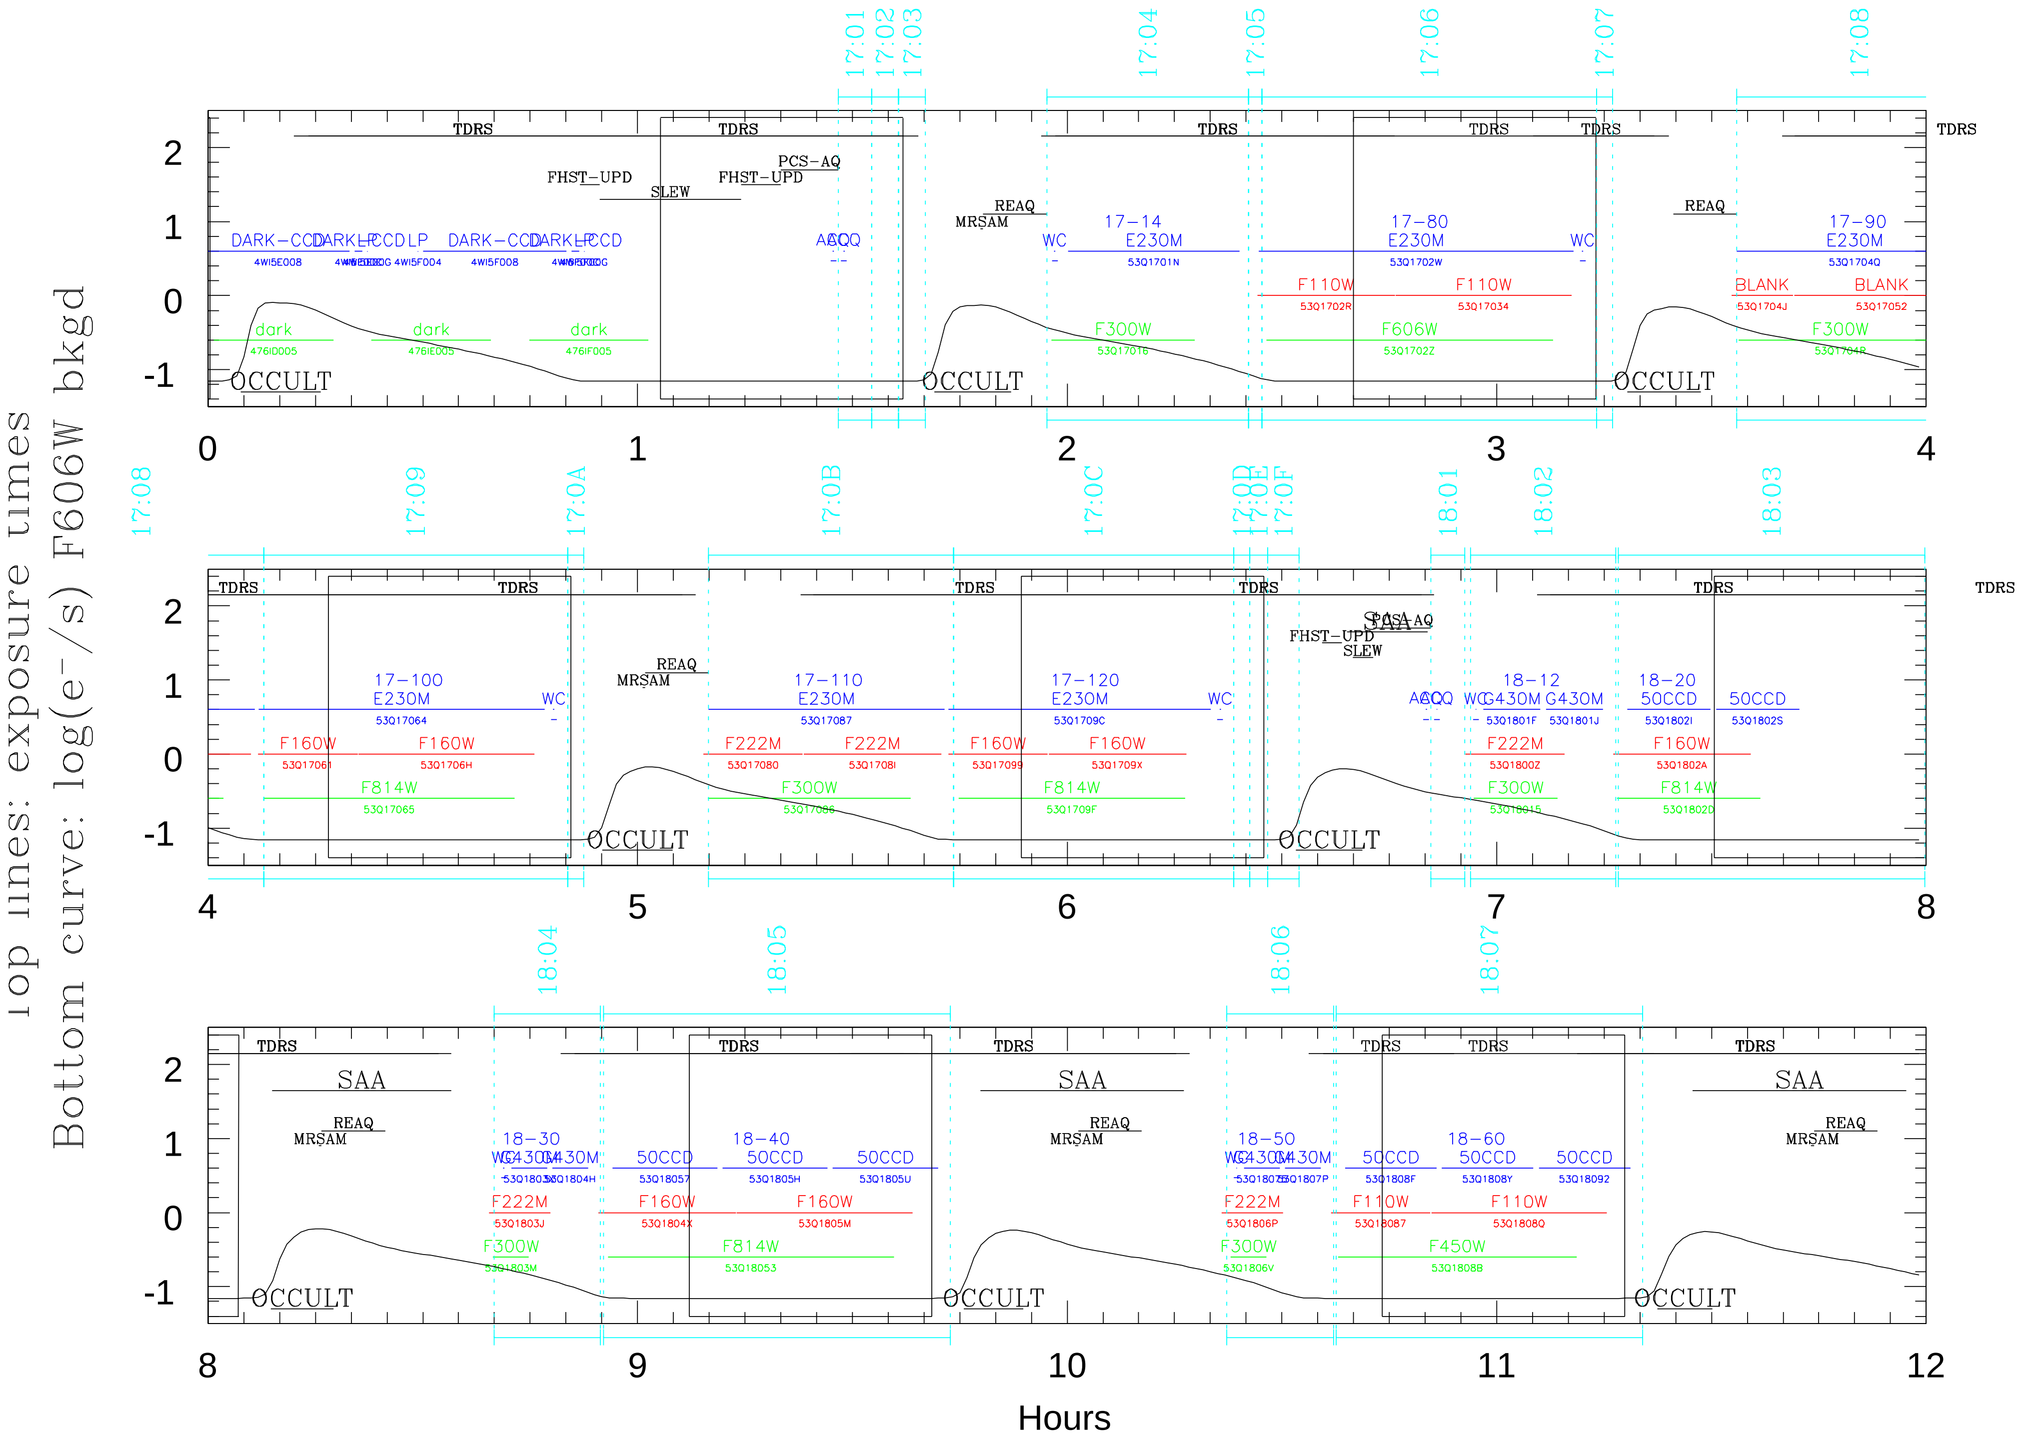
Day 273 = September 30



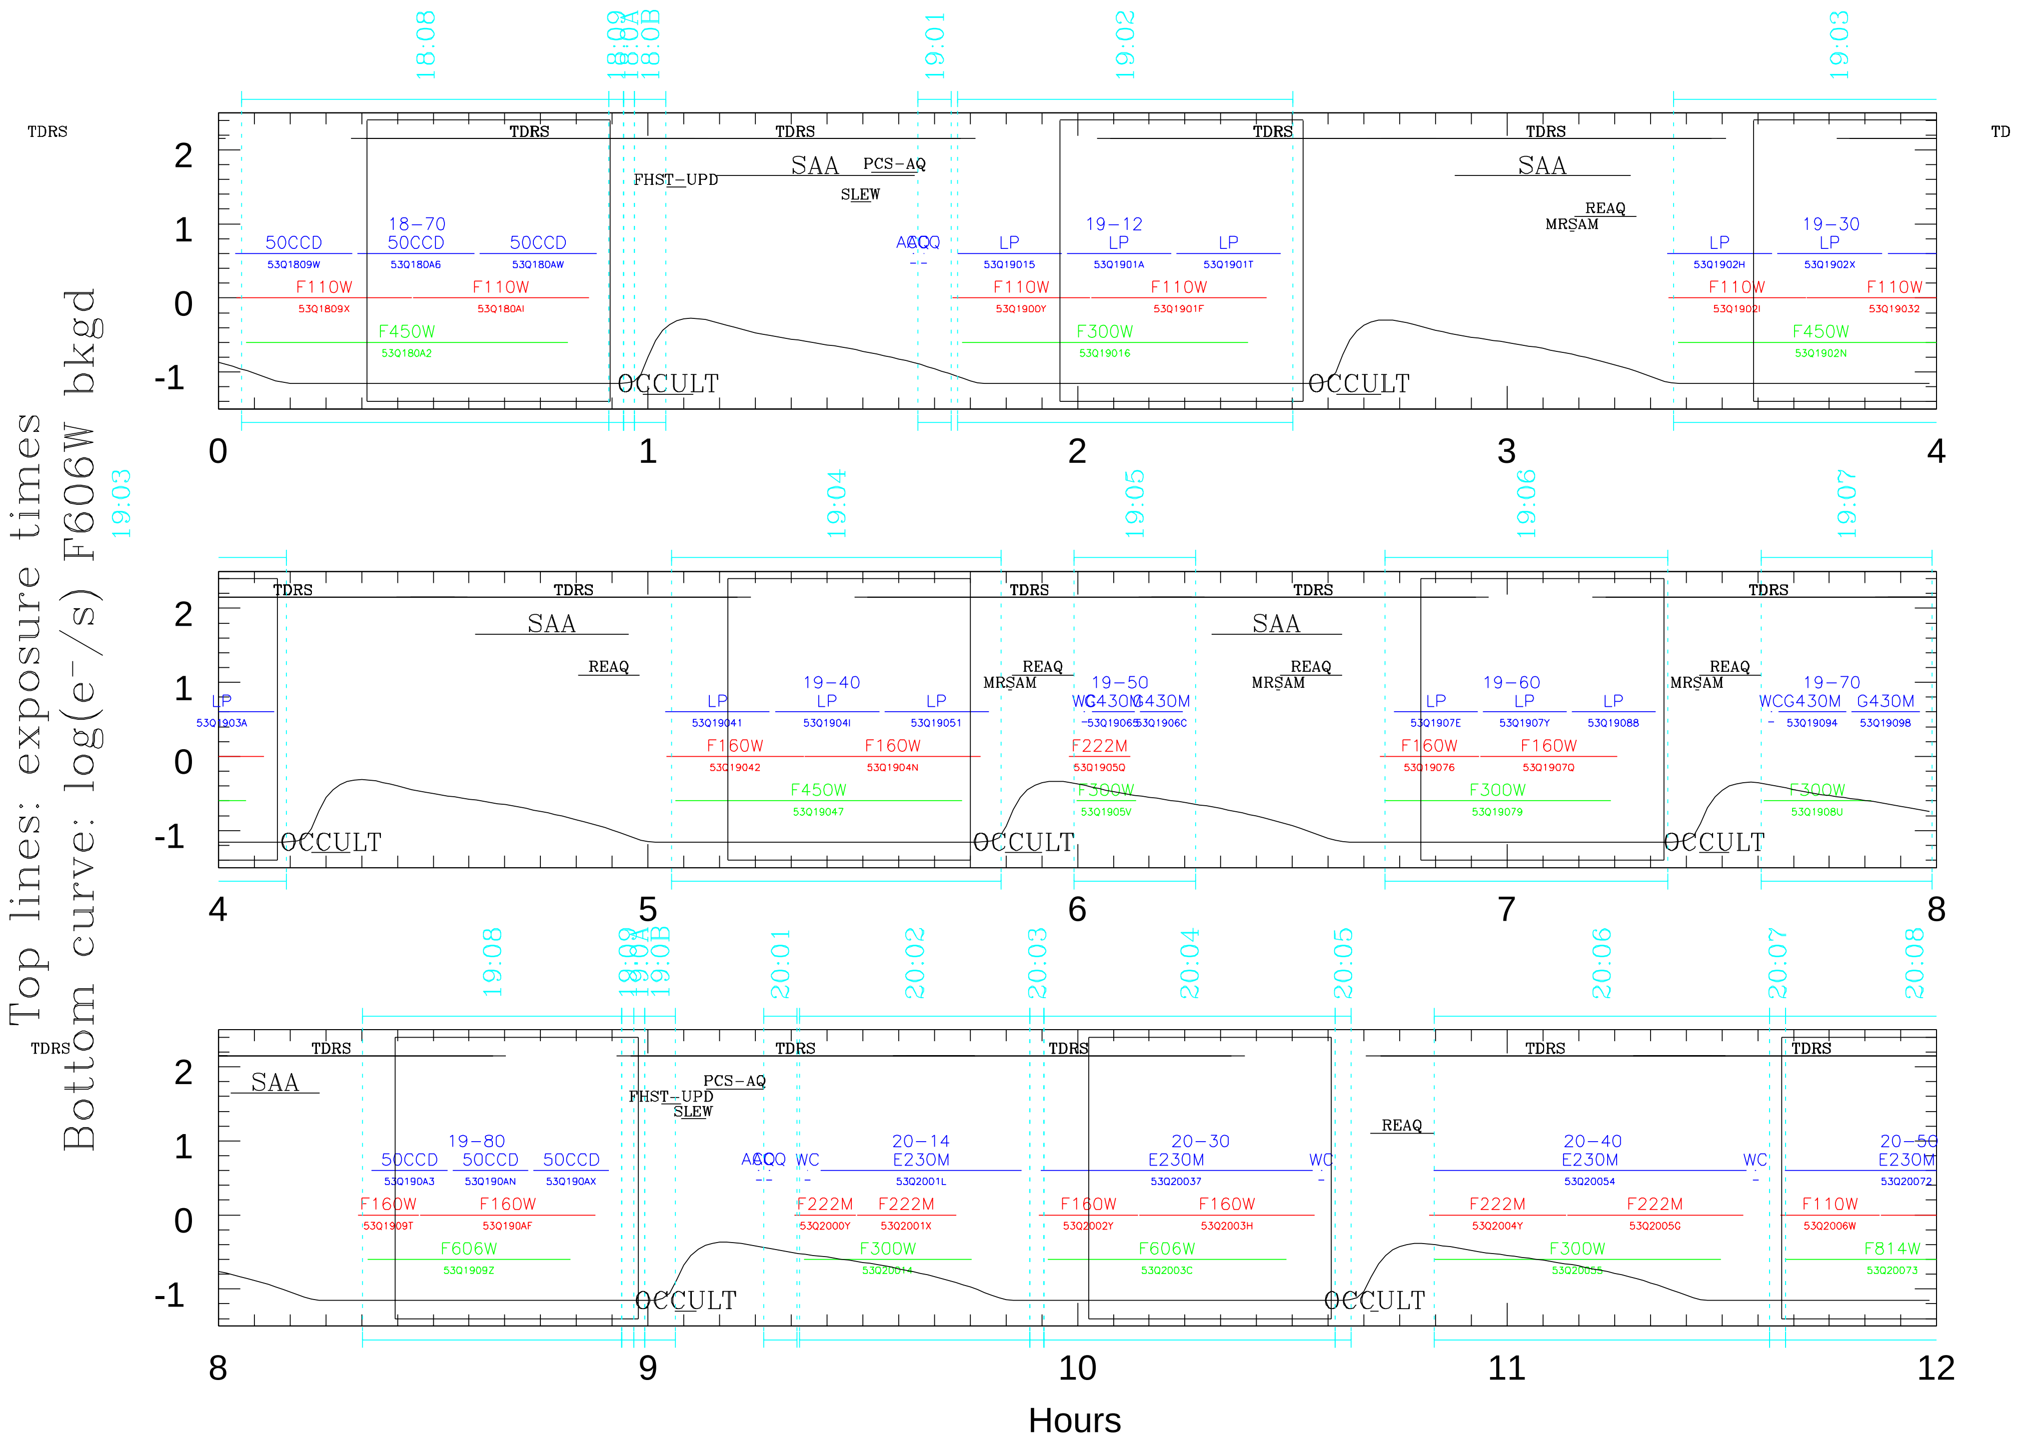
Day 273.5 = September 30



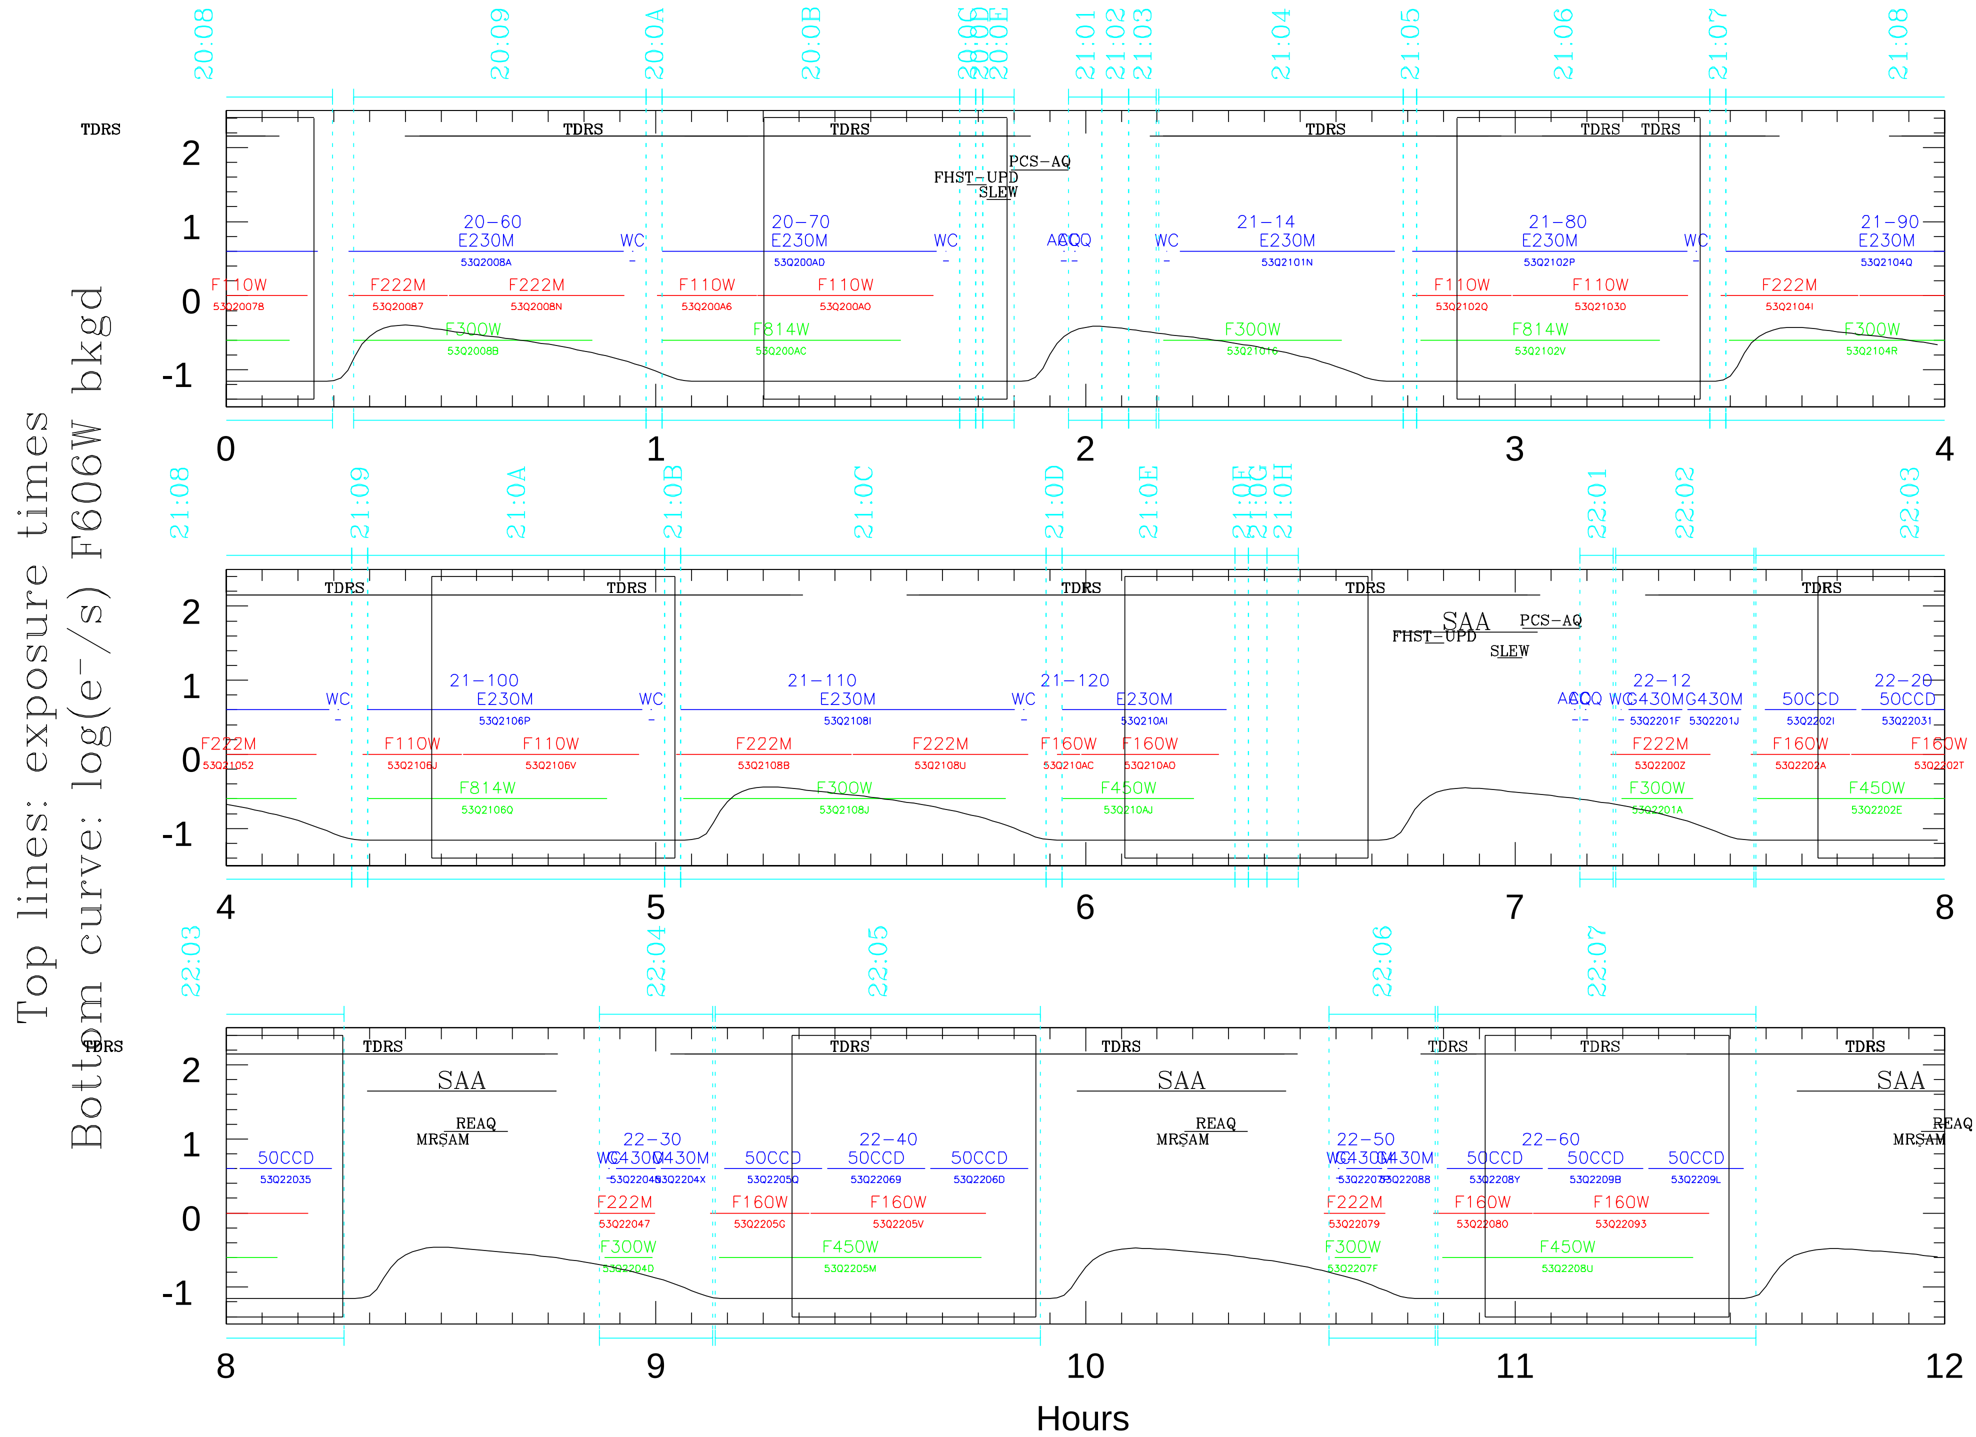
Day 274 = October 1



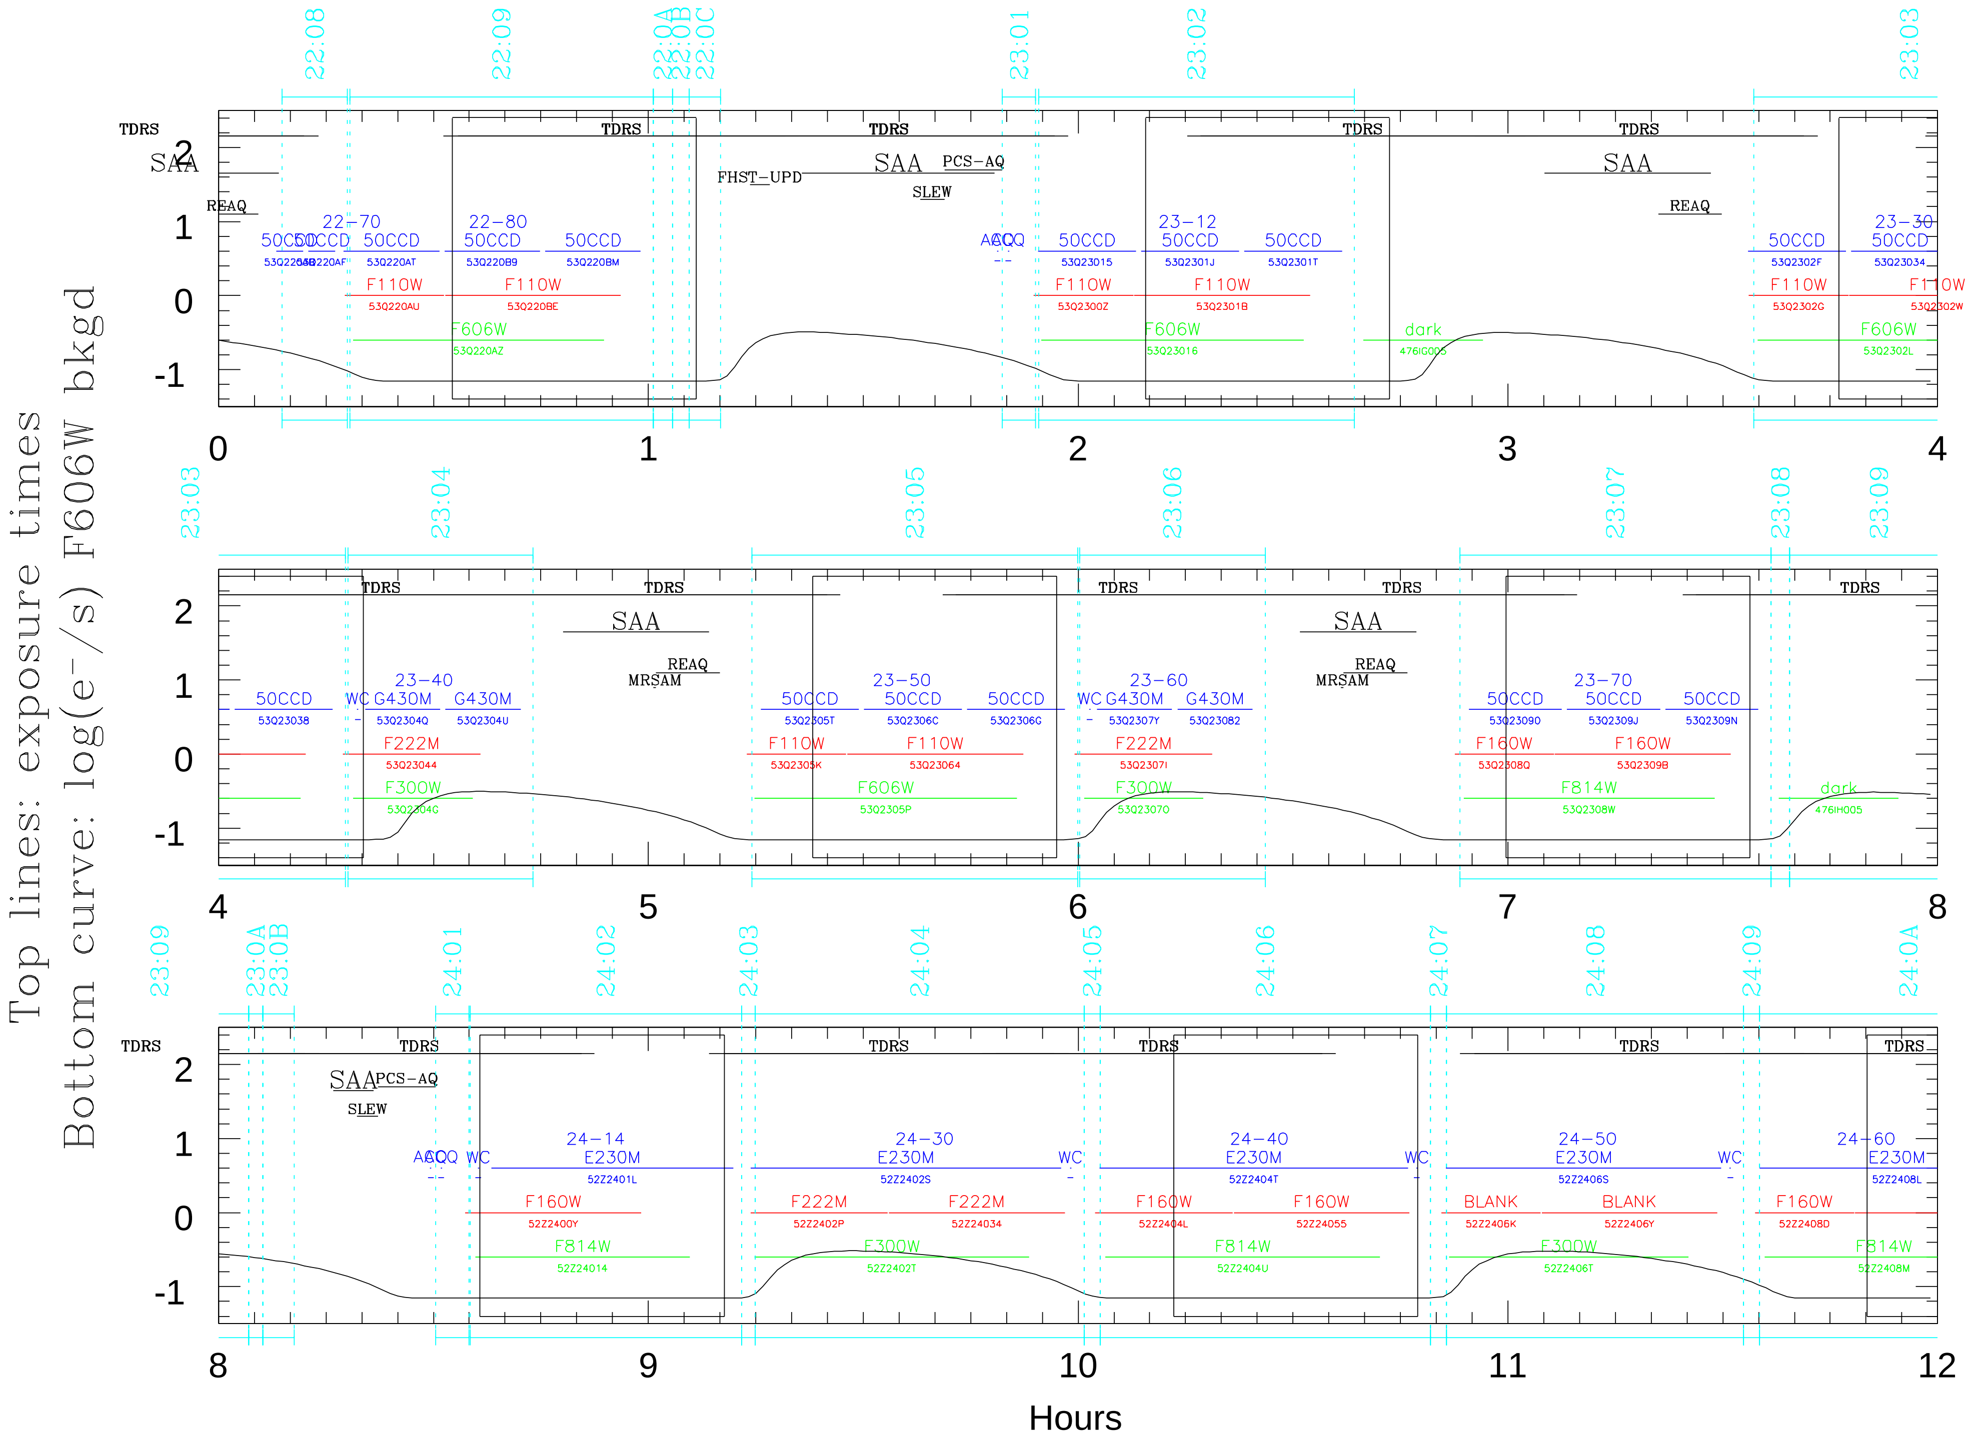
Day 274.5 = October 1



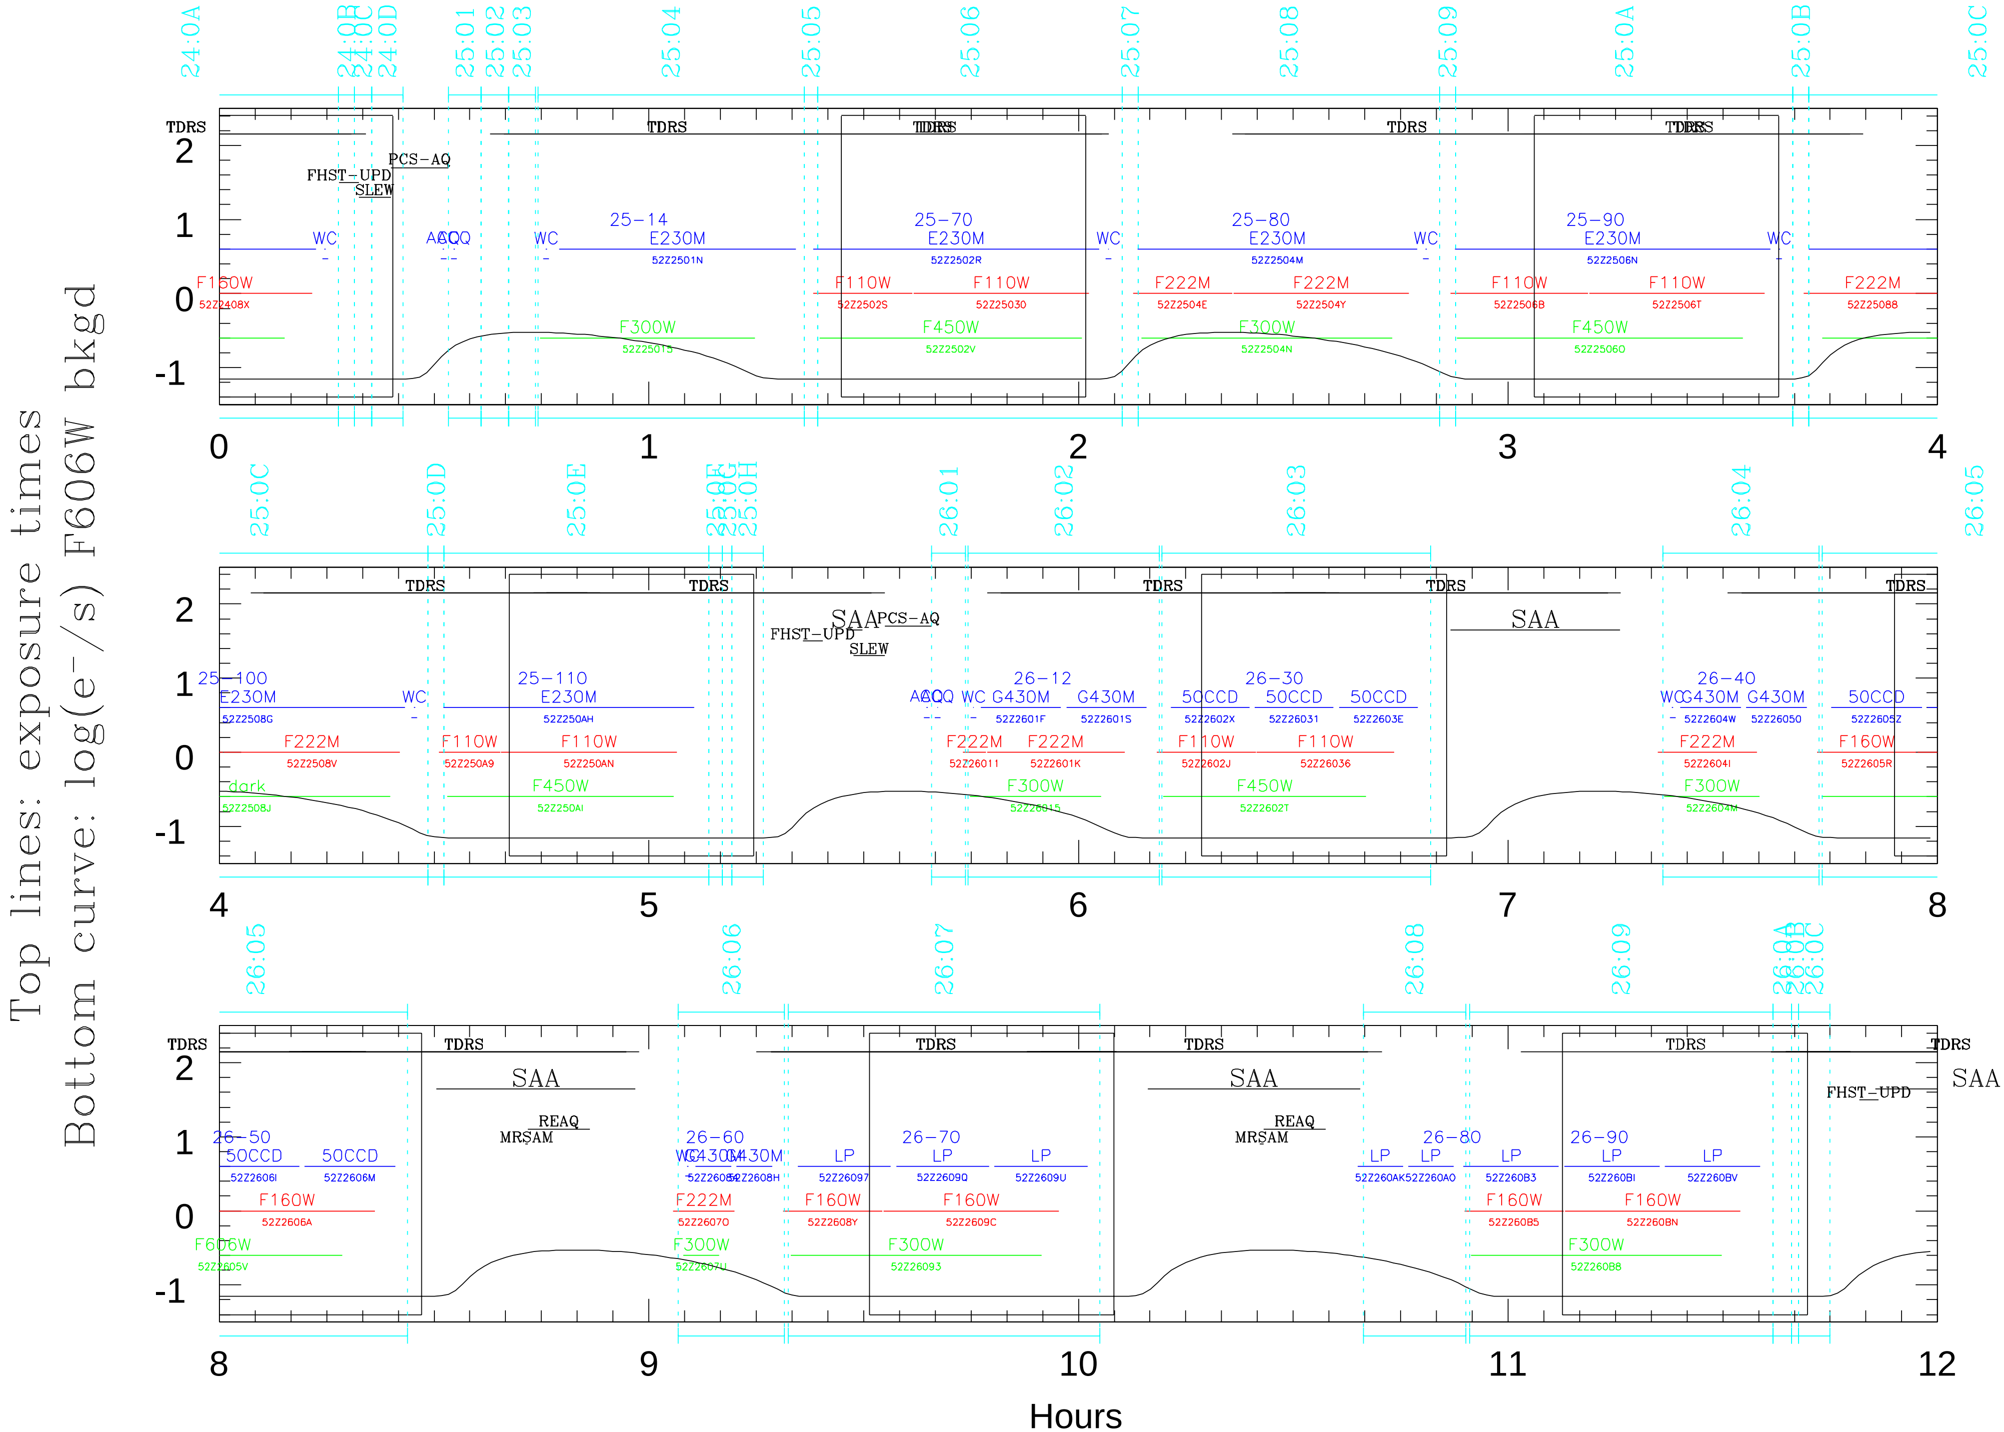
Day 275 = October 2



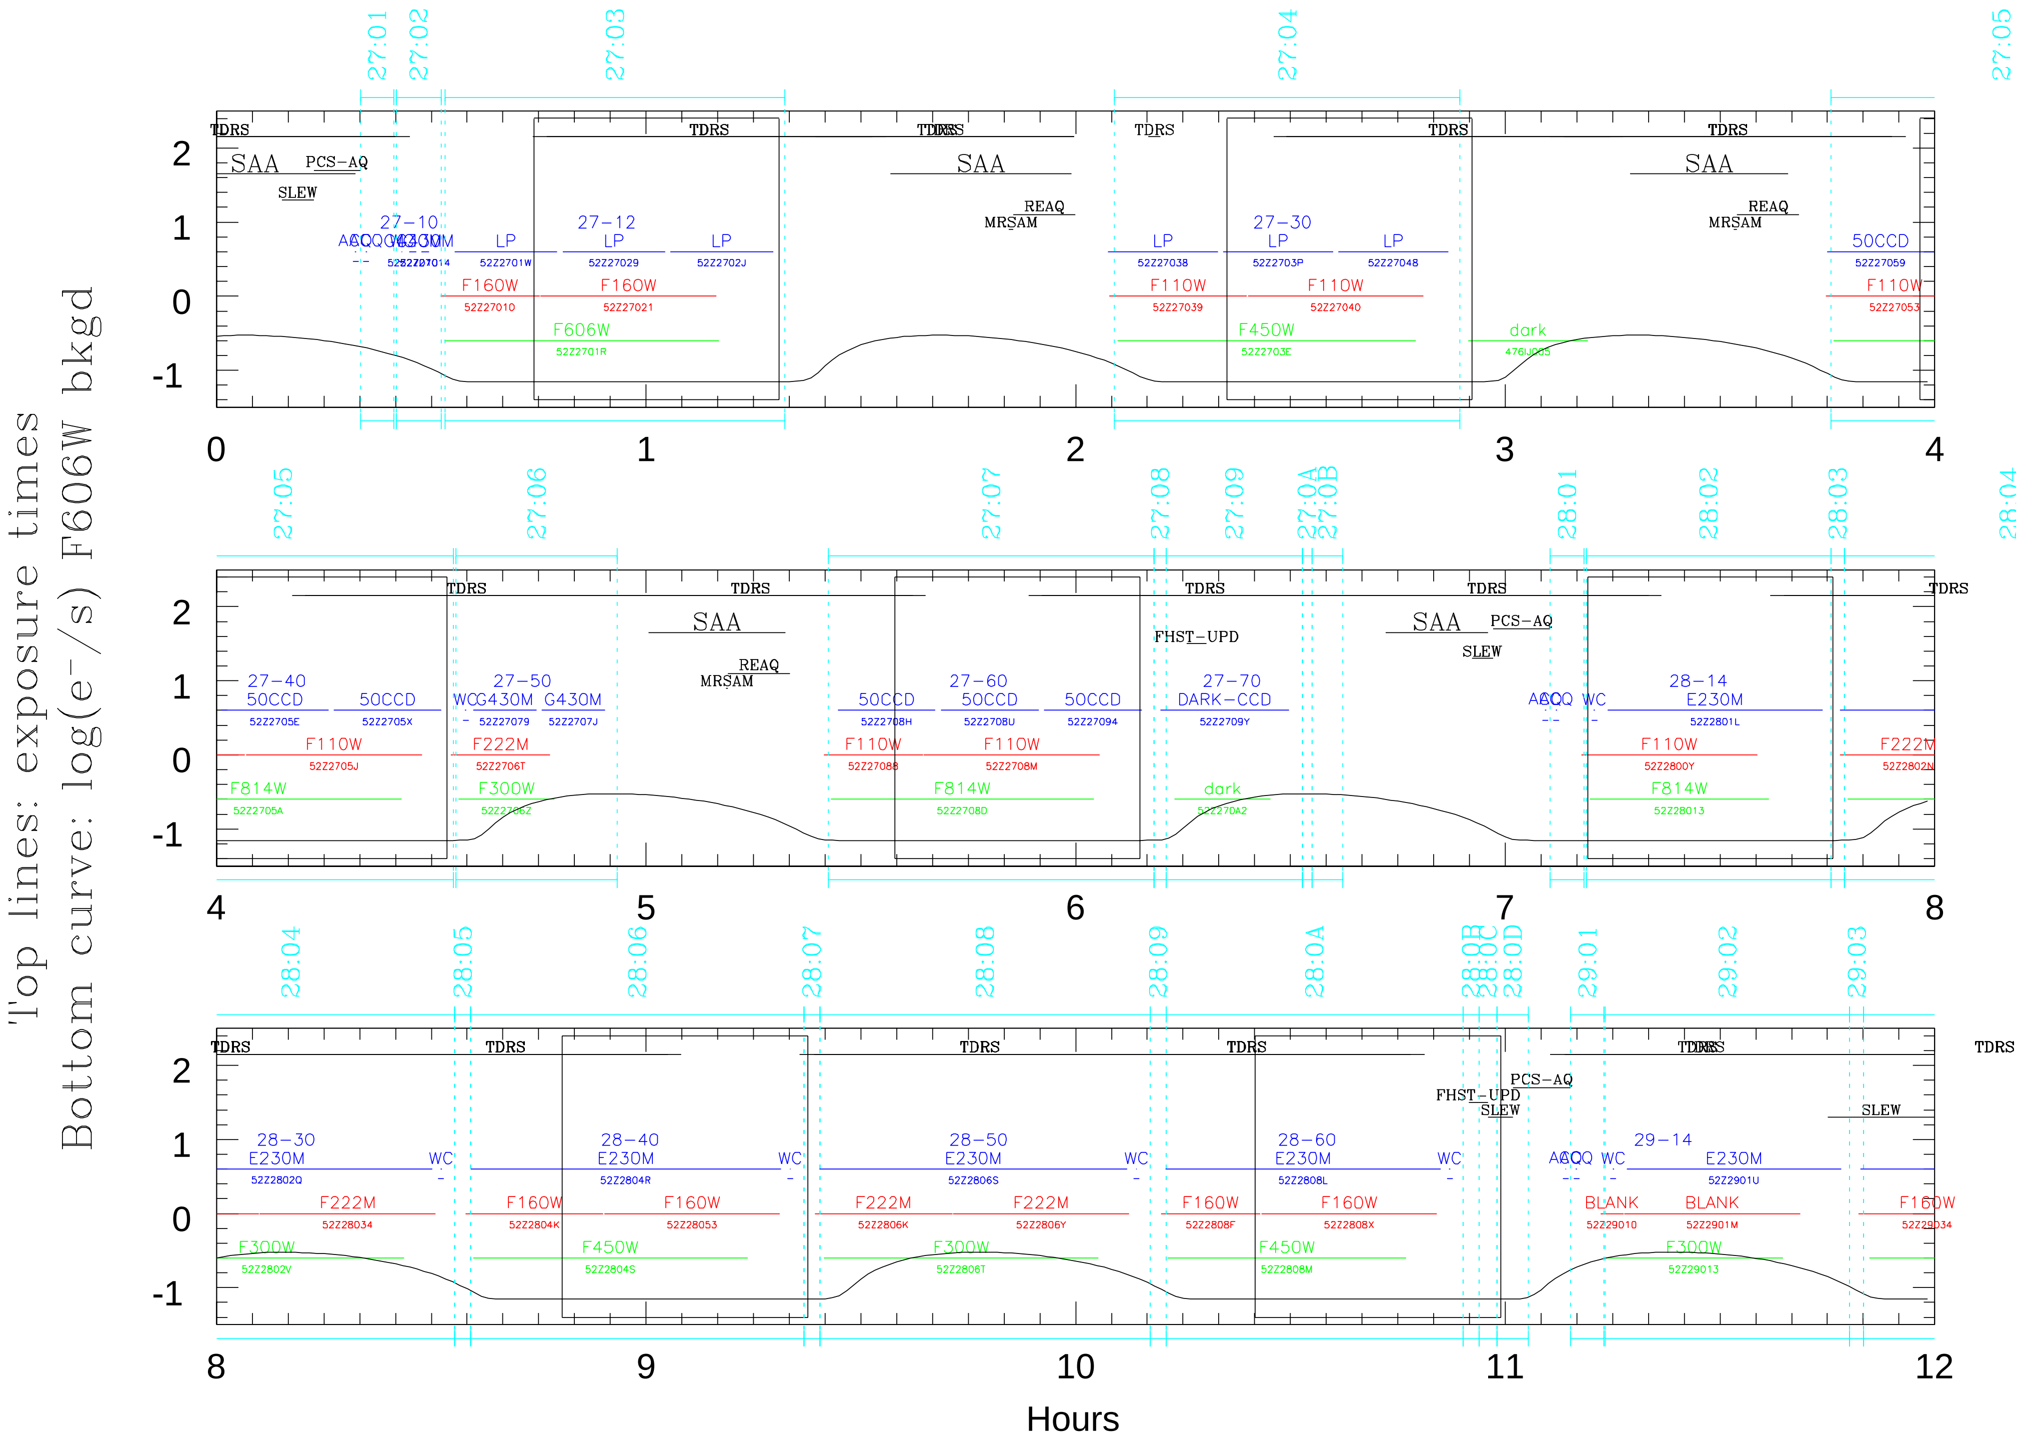
Day 275.5 = October 2



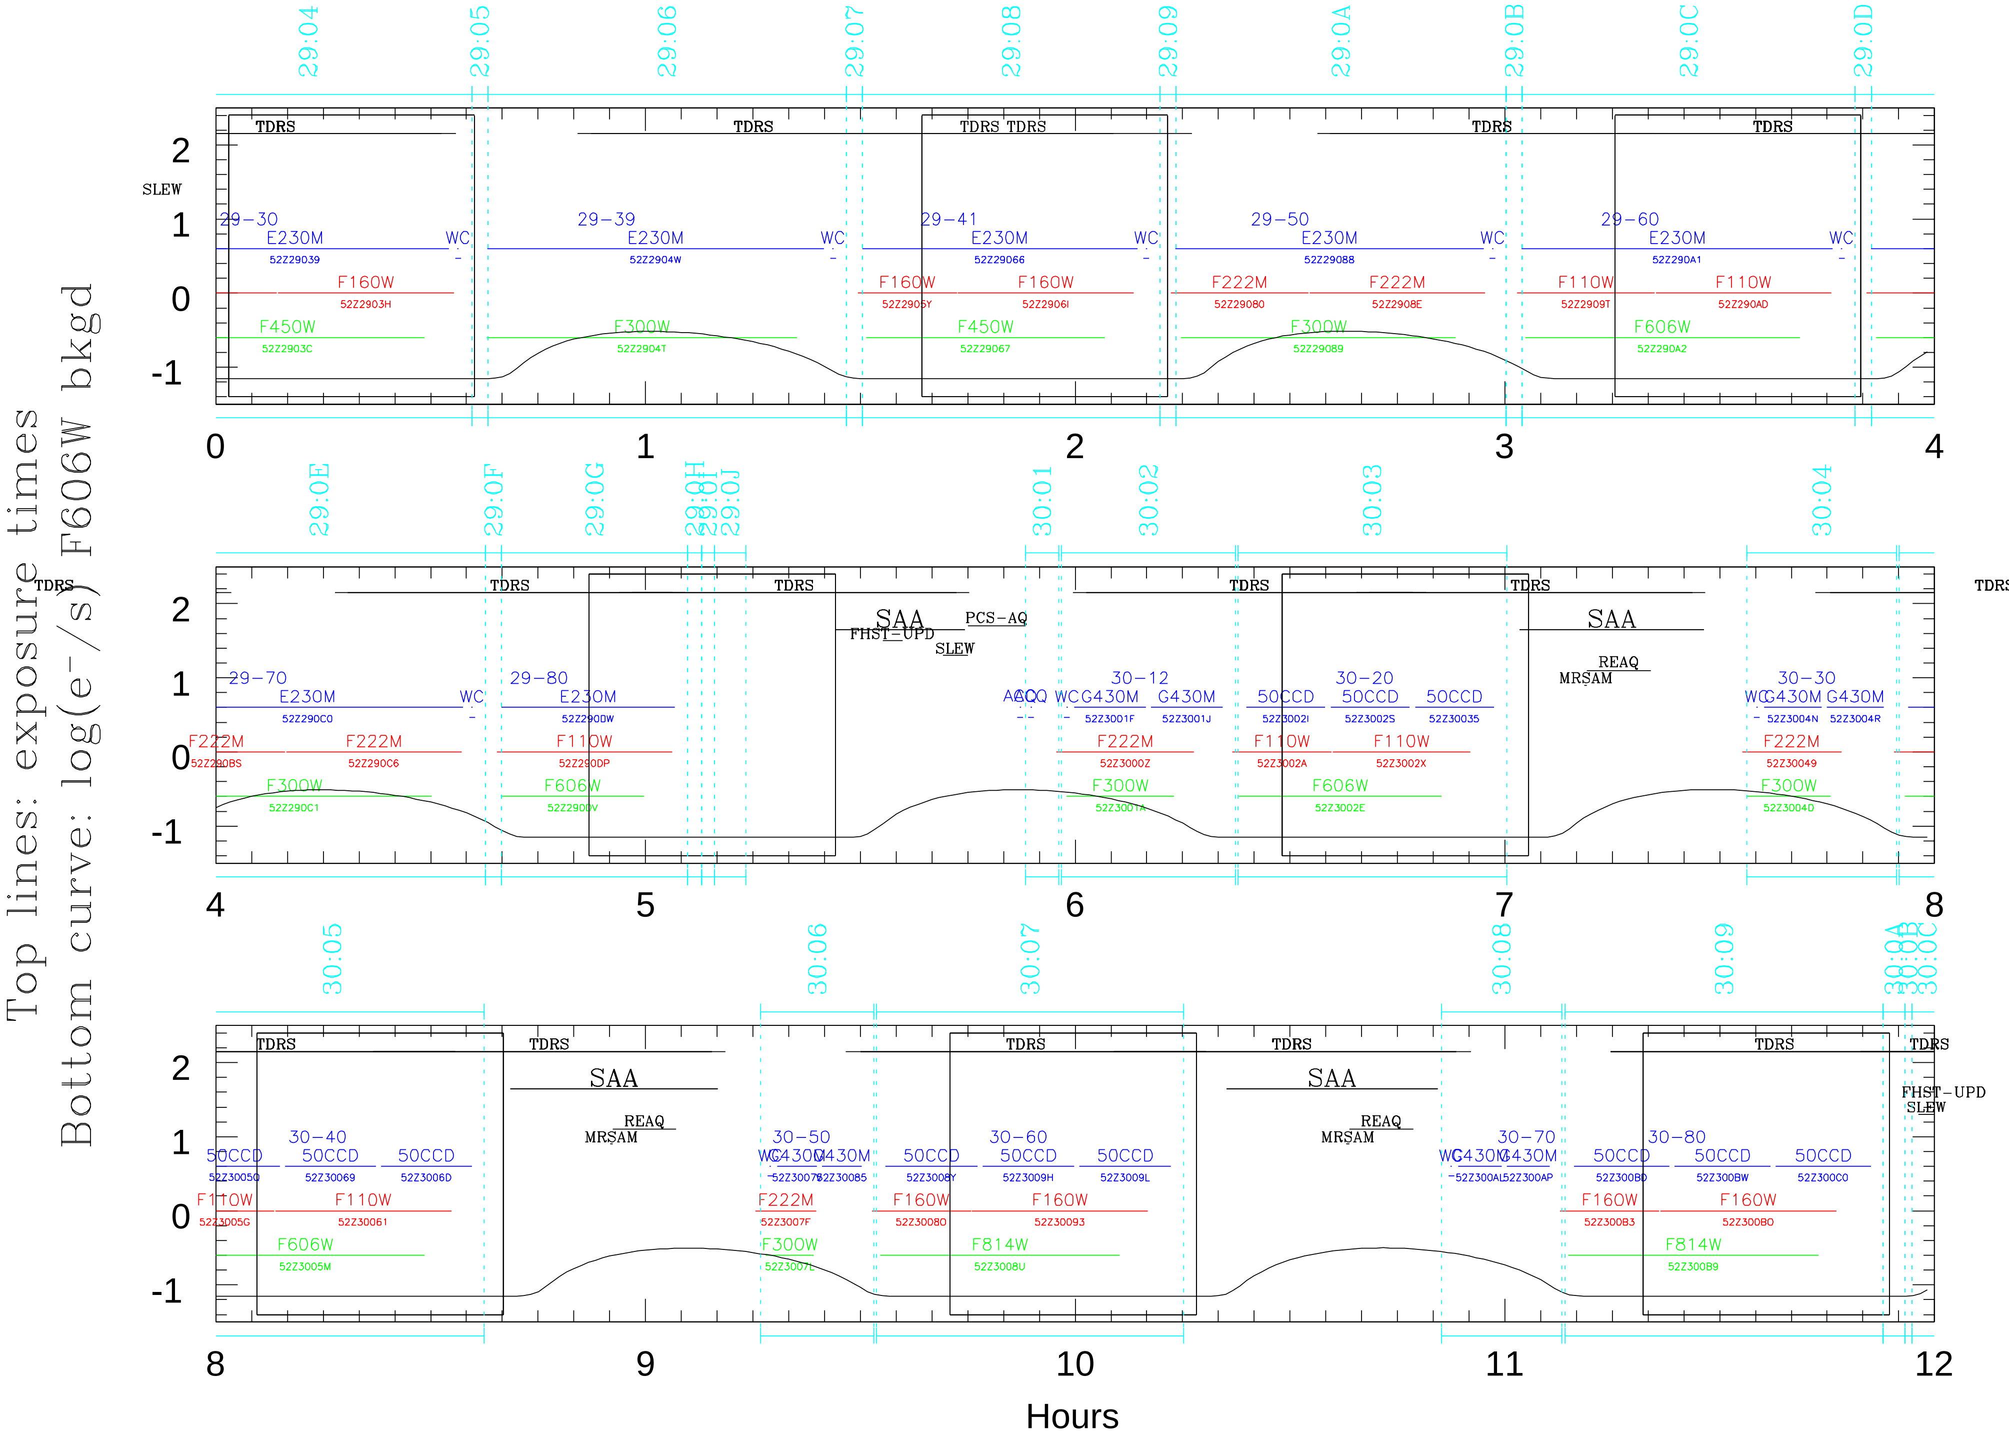
Day 276 = October 3



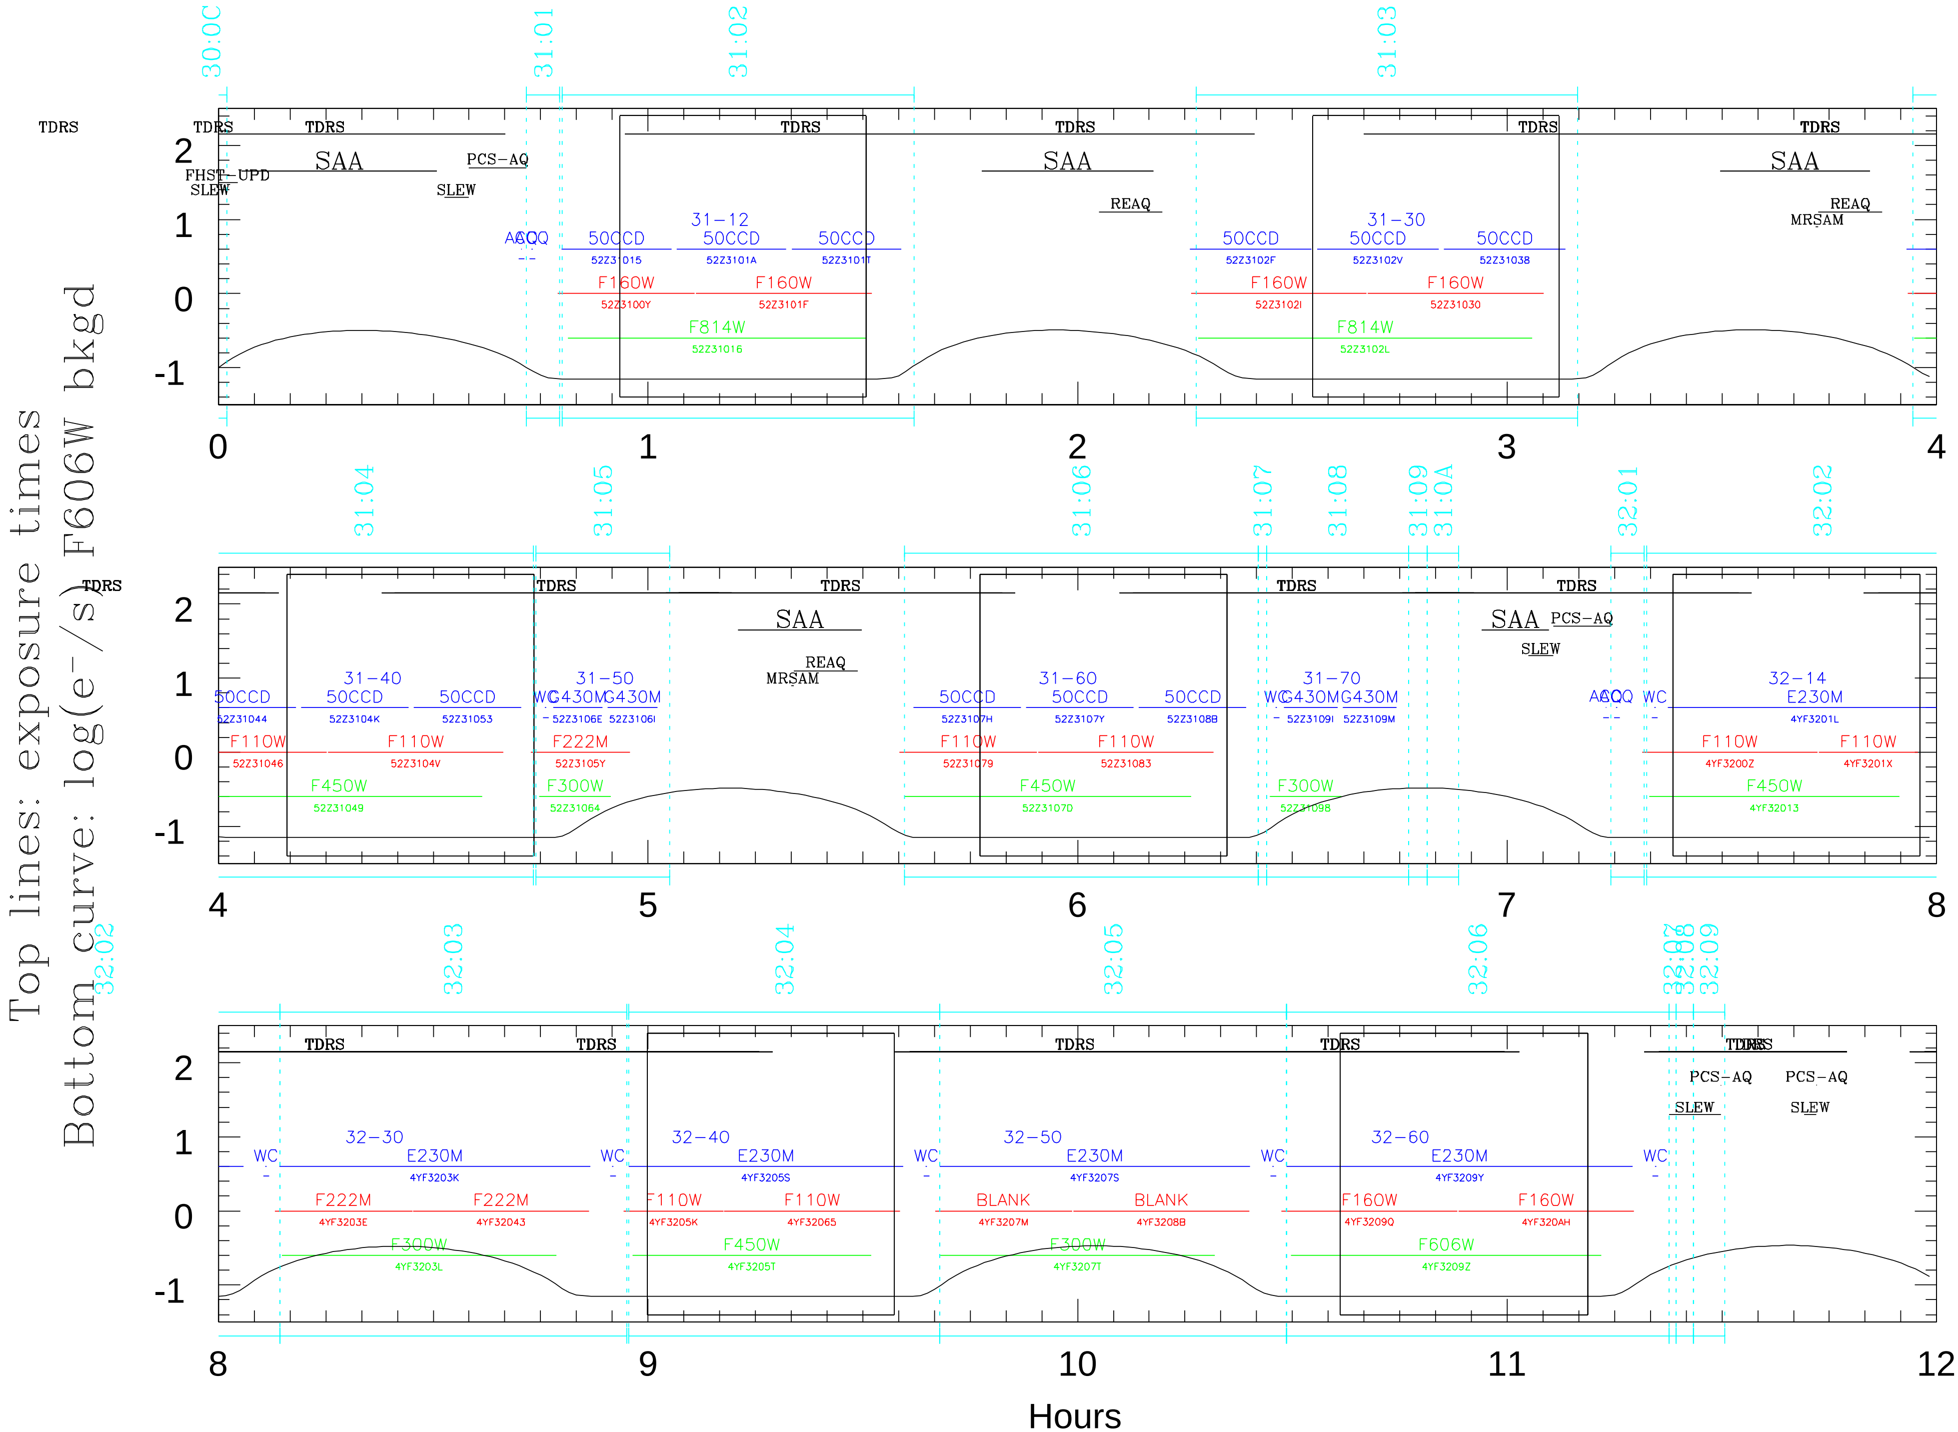
Day 276.5 = October 3



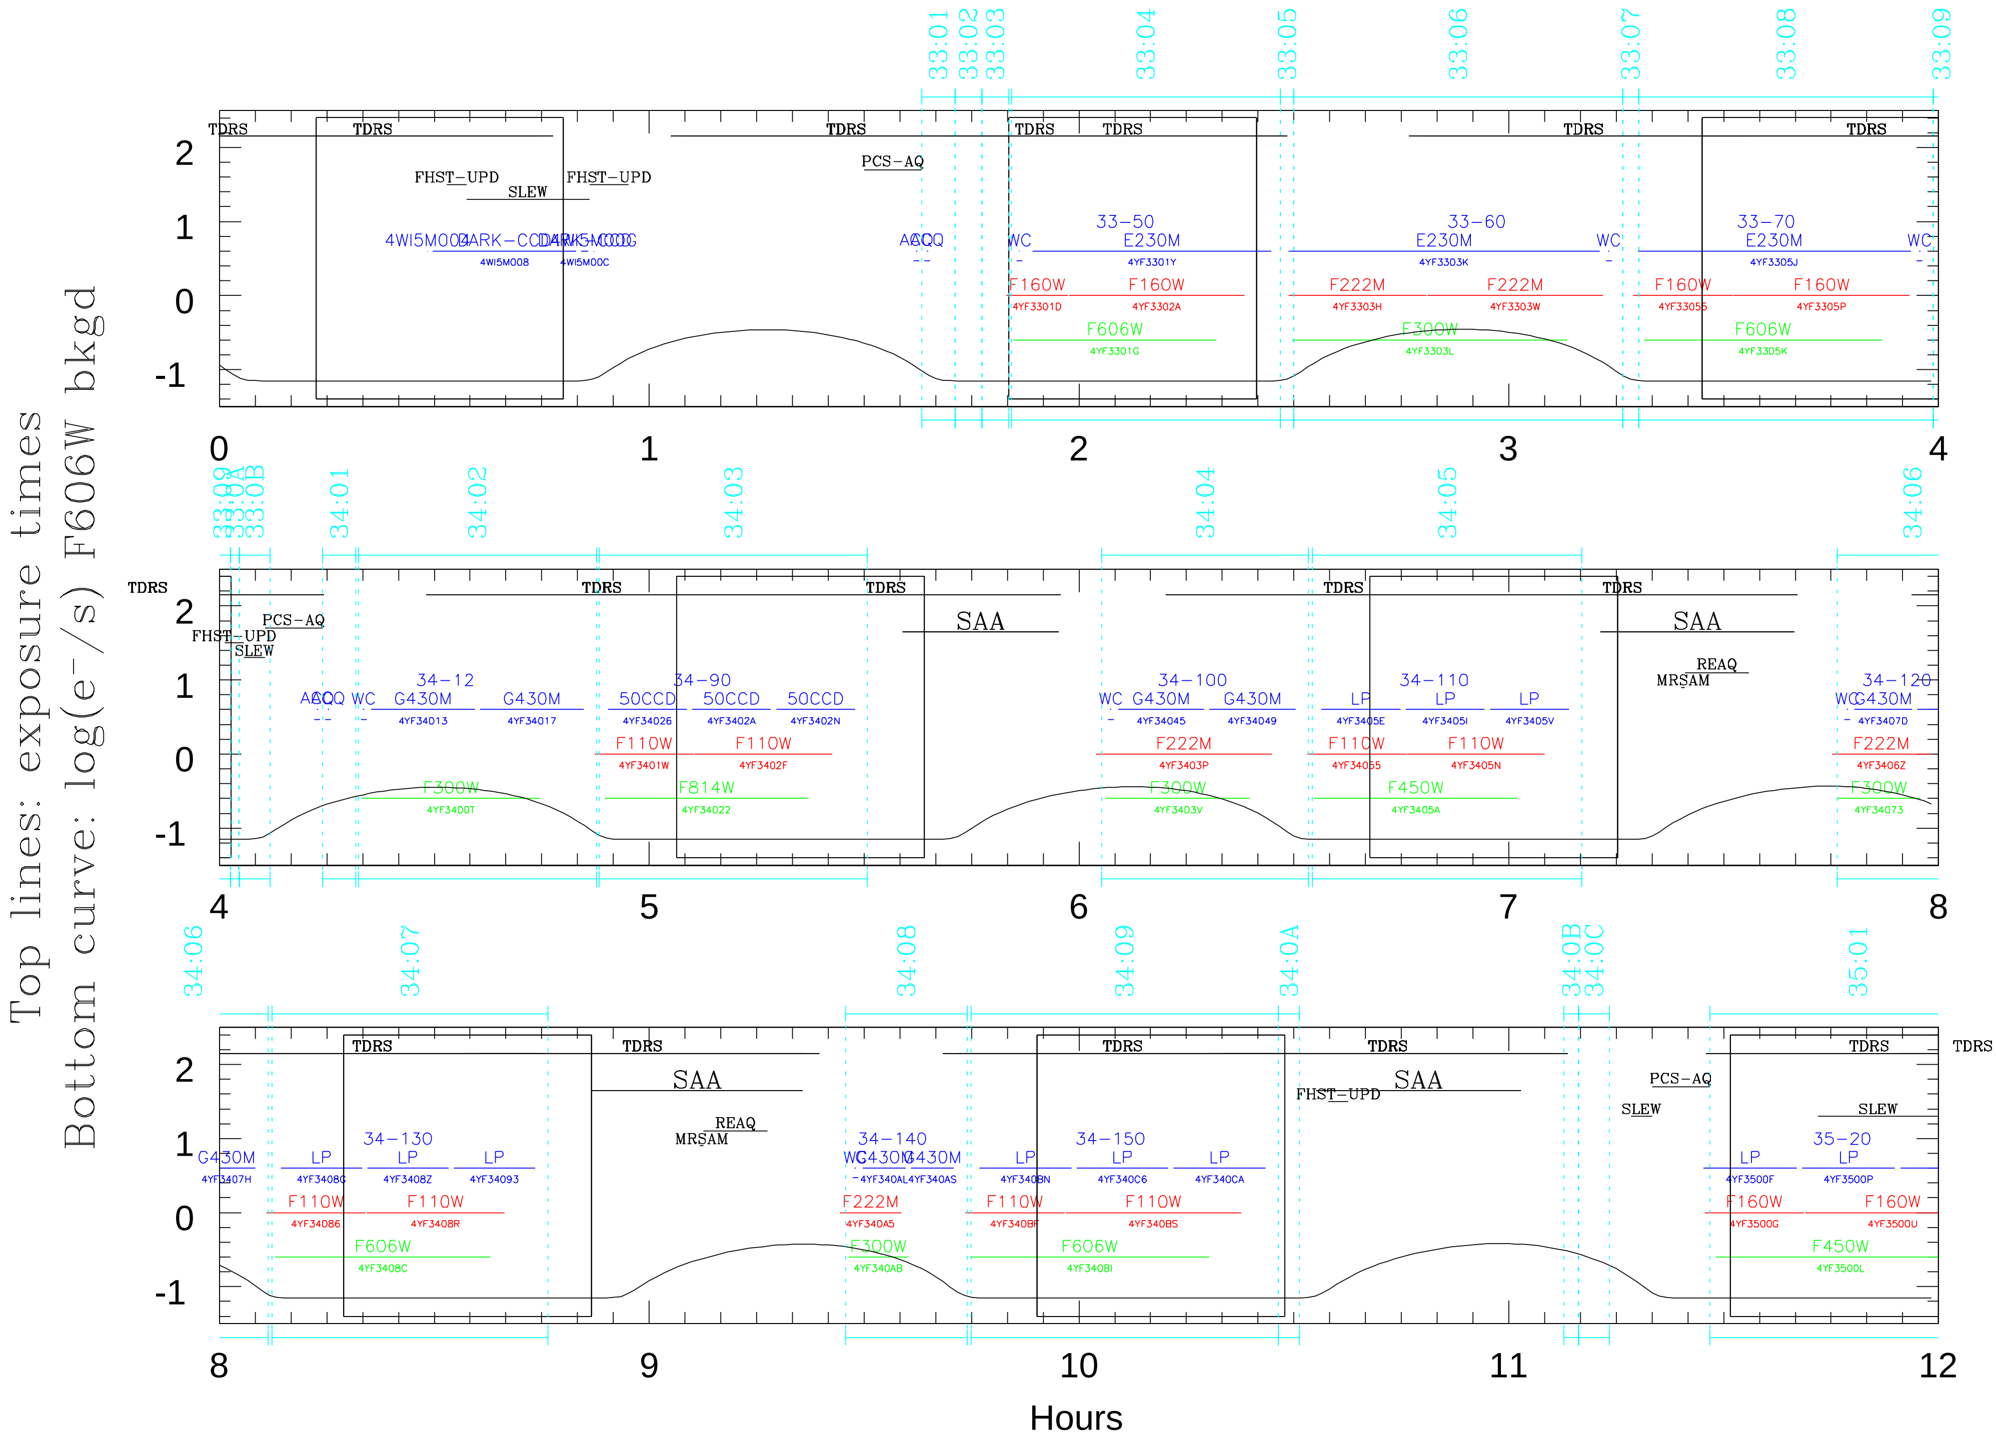
Day 277 = October 4



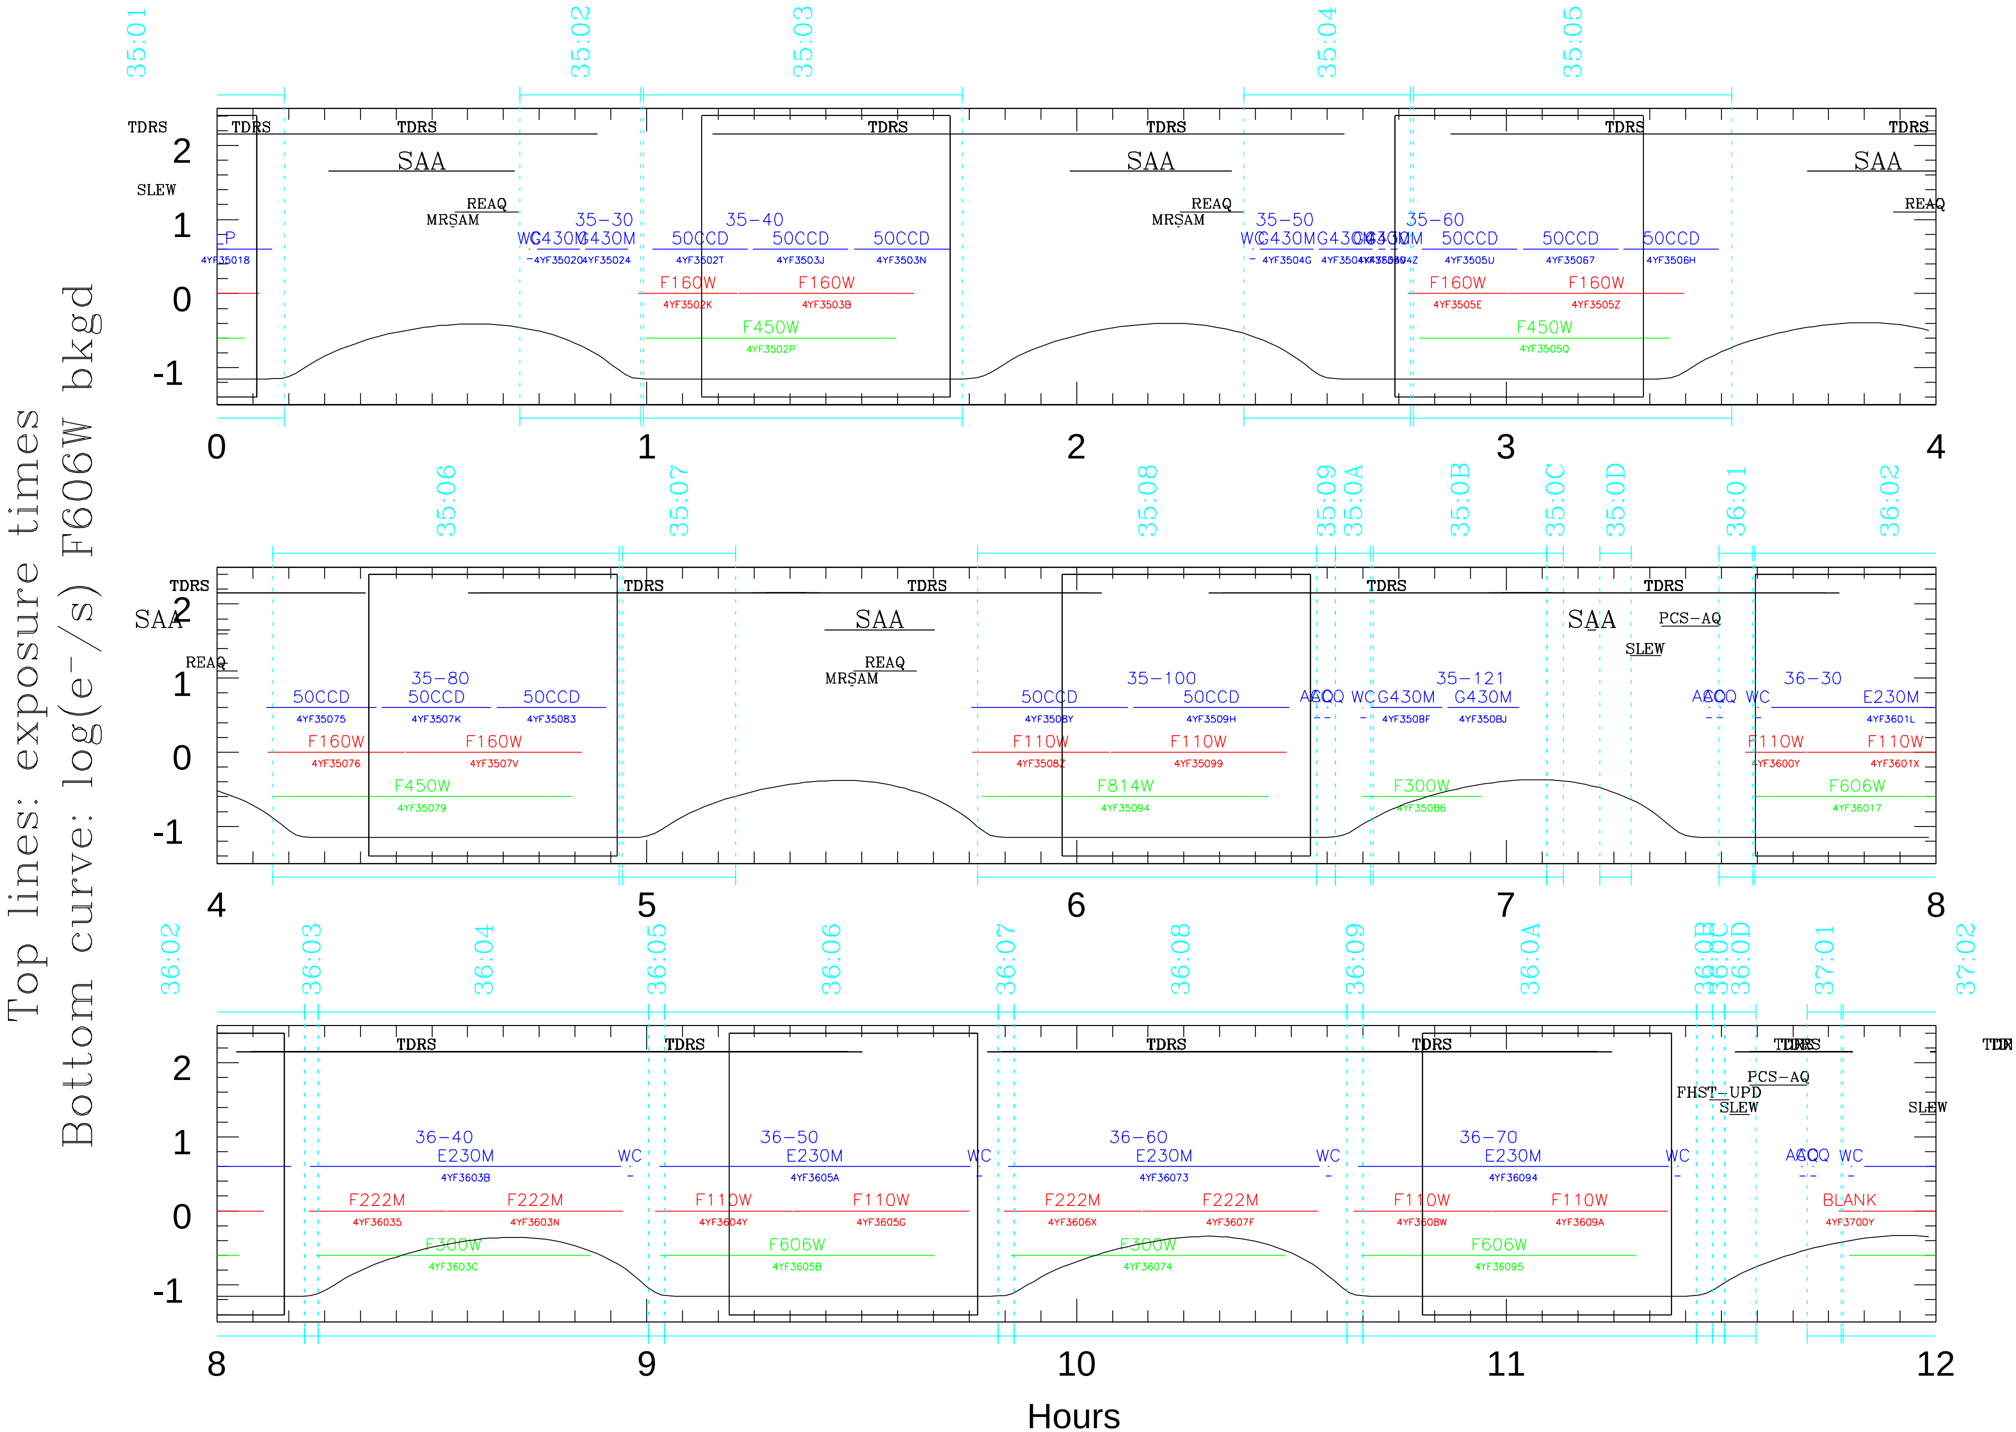
Day 277.5 = October 4



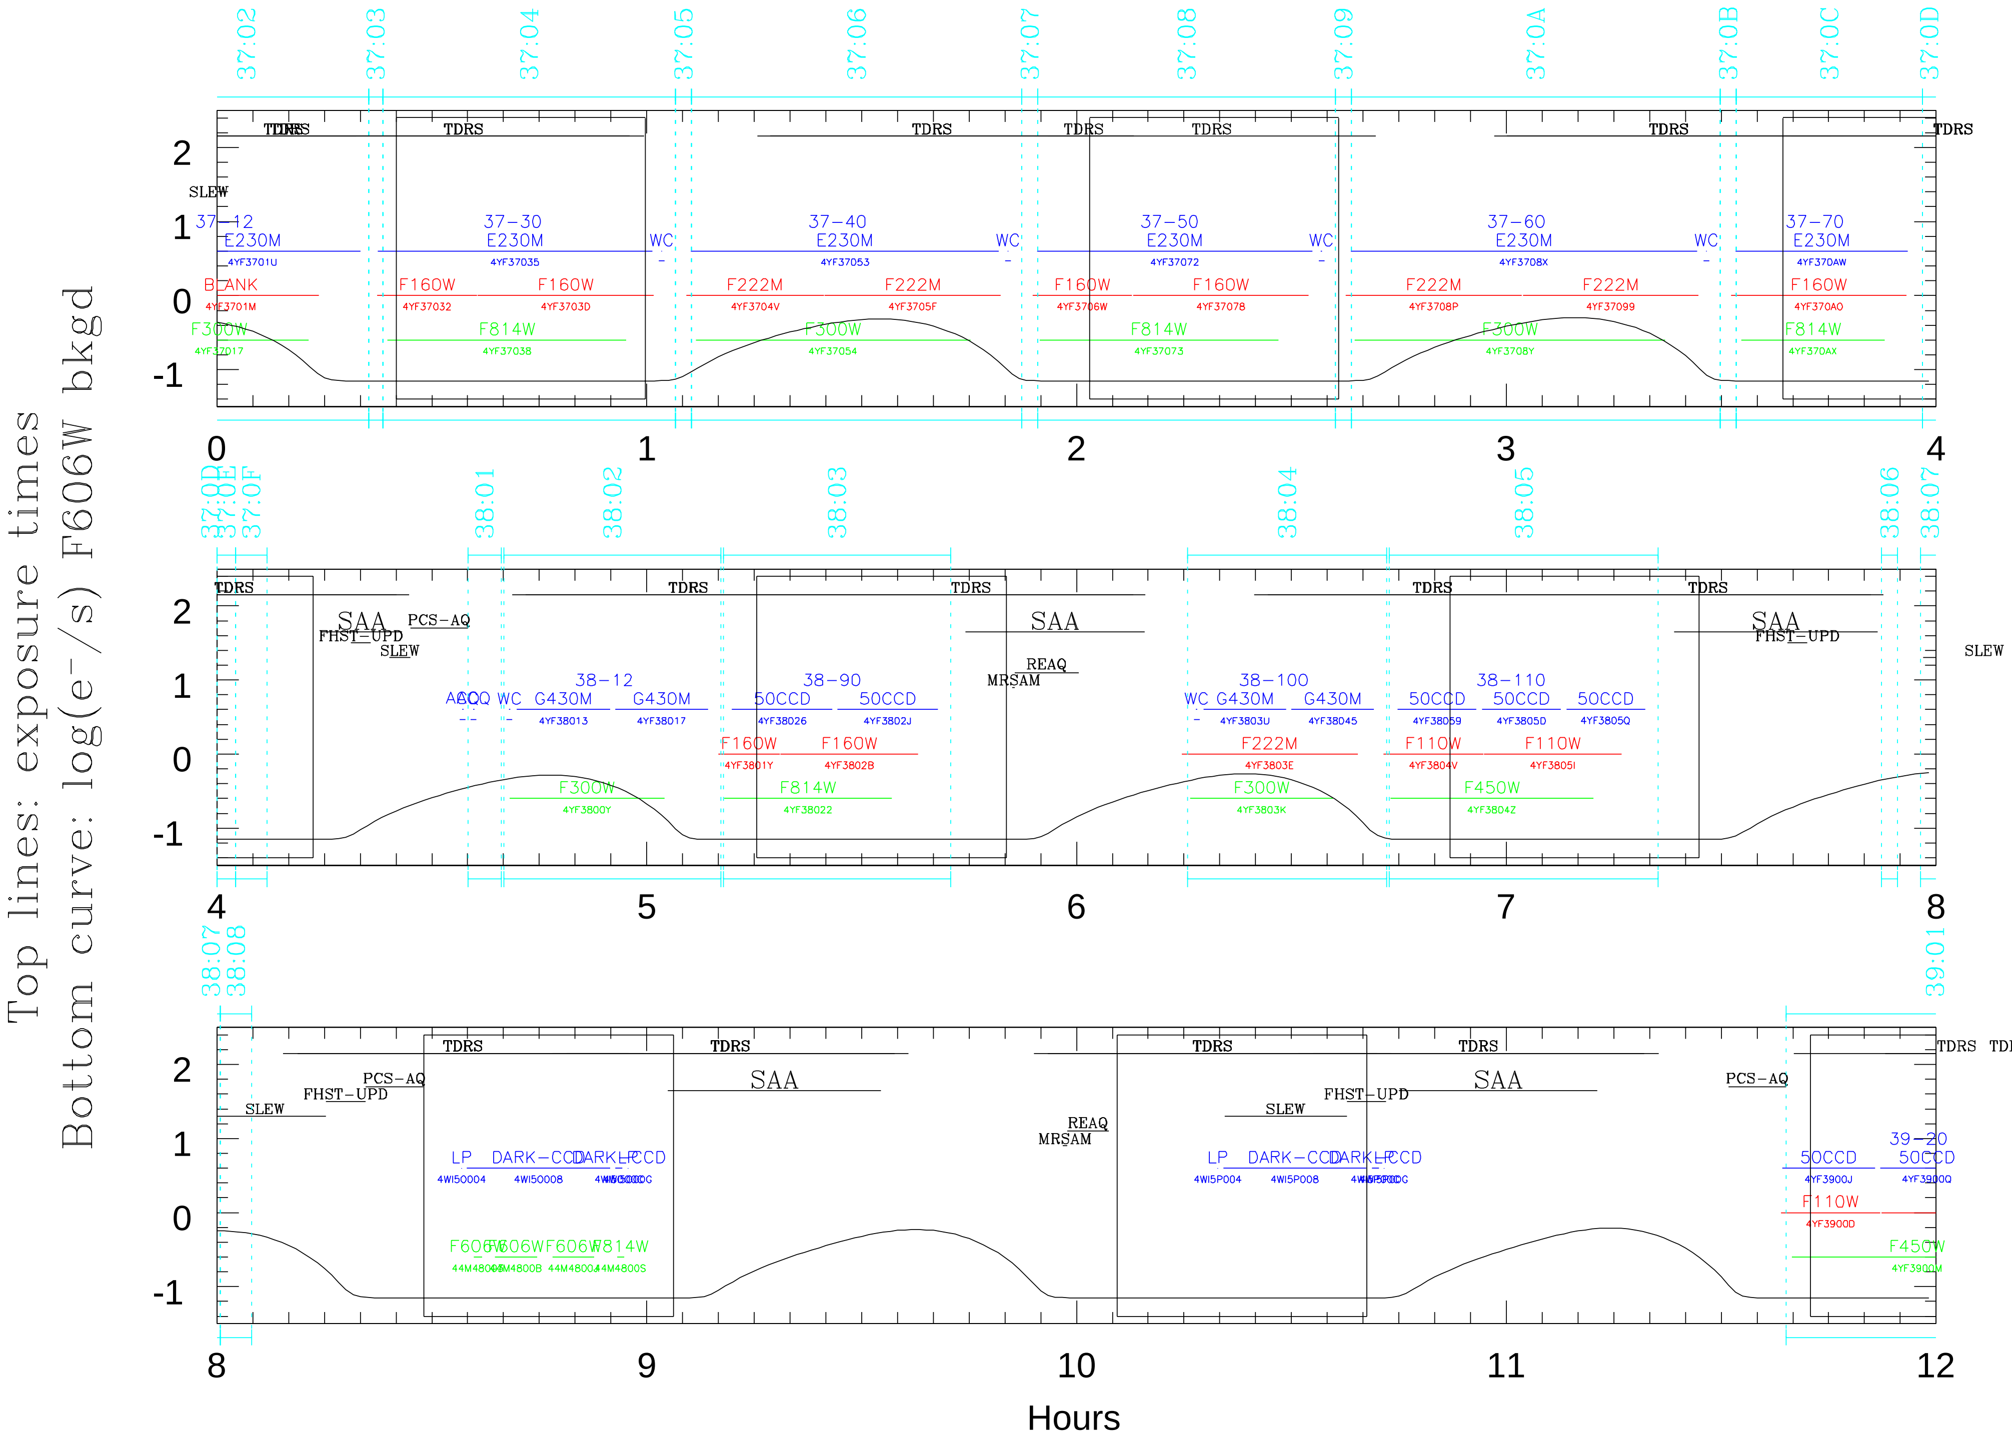
Day 278 = October 5



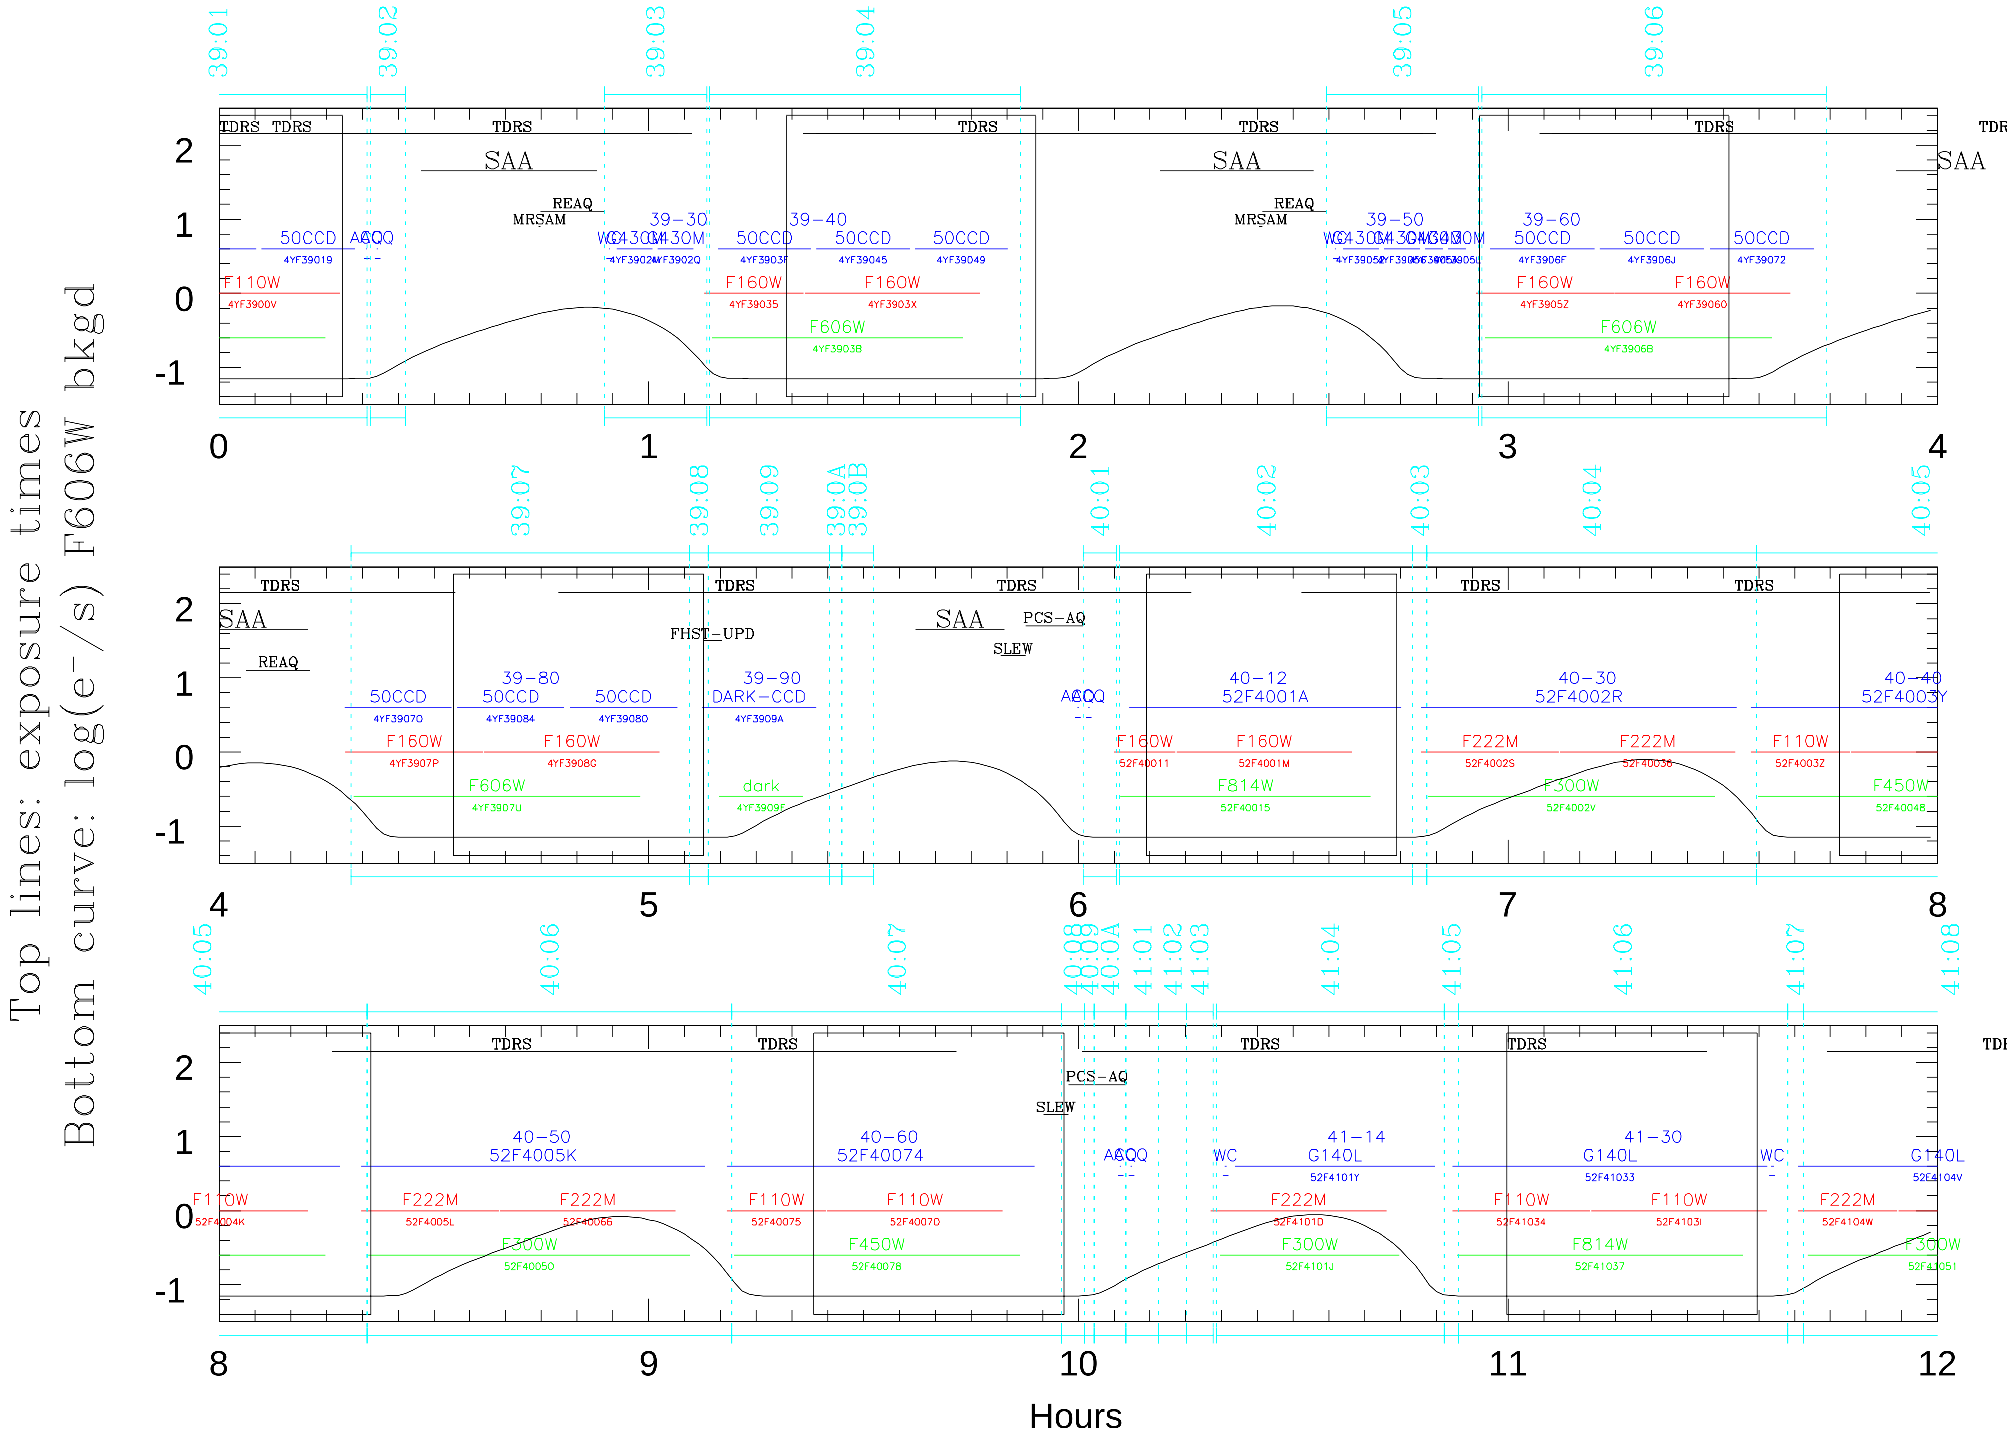
Day 278.5 = October 5



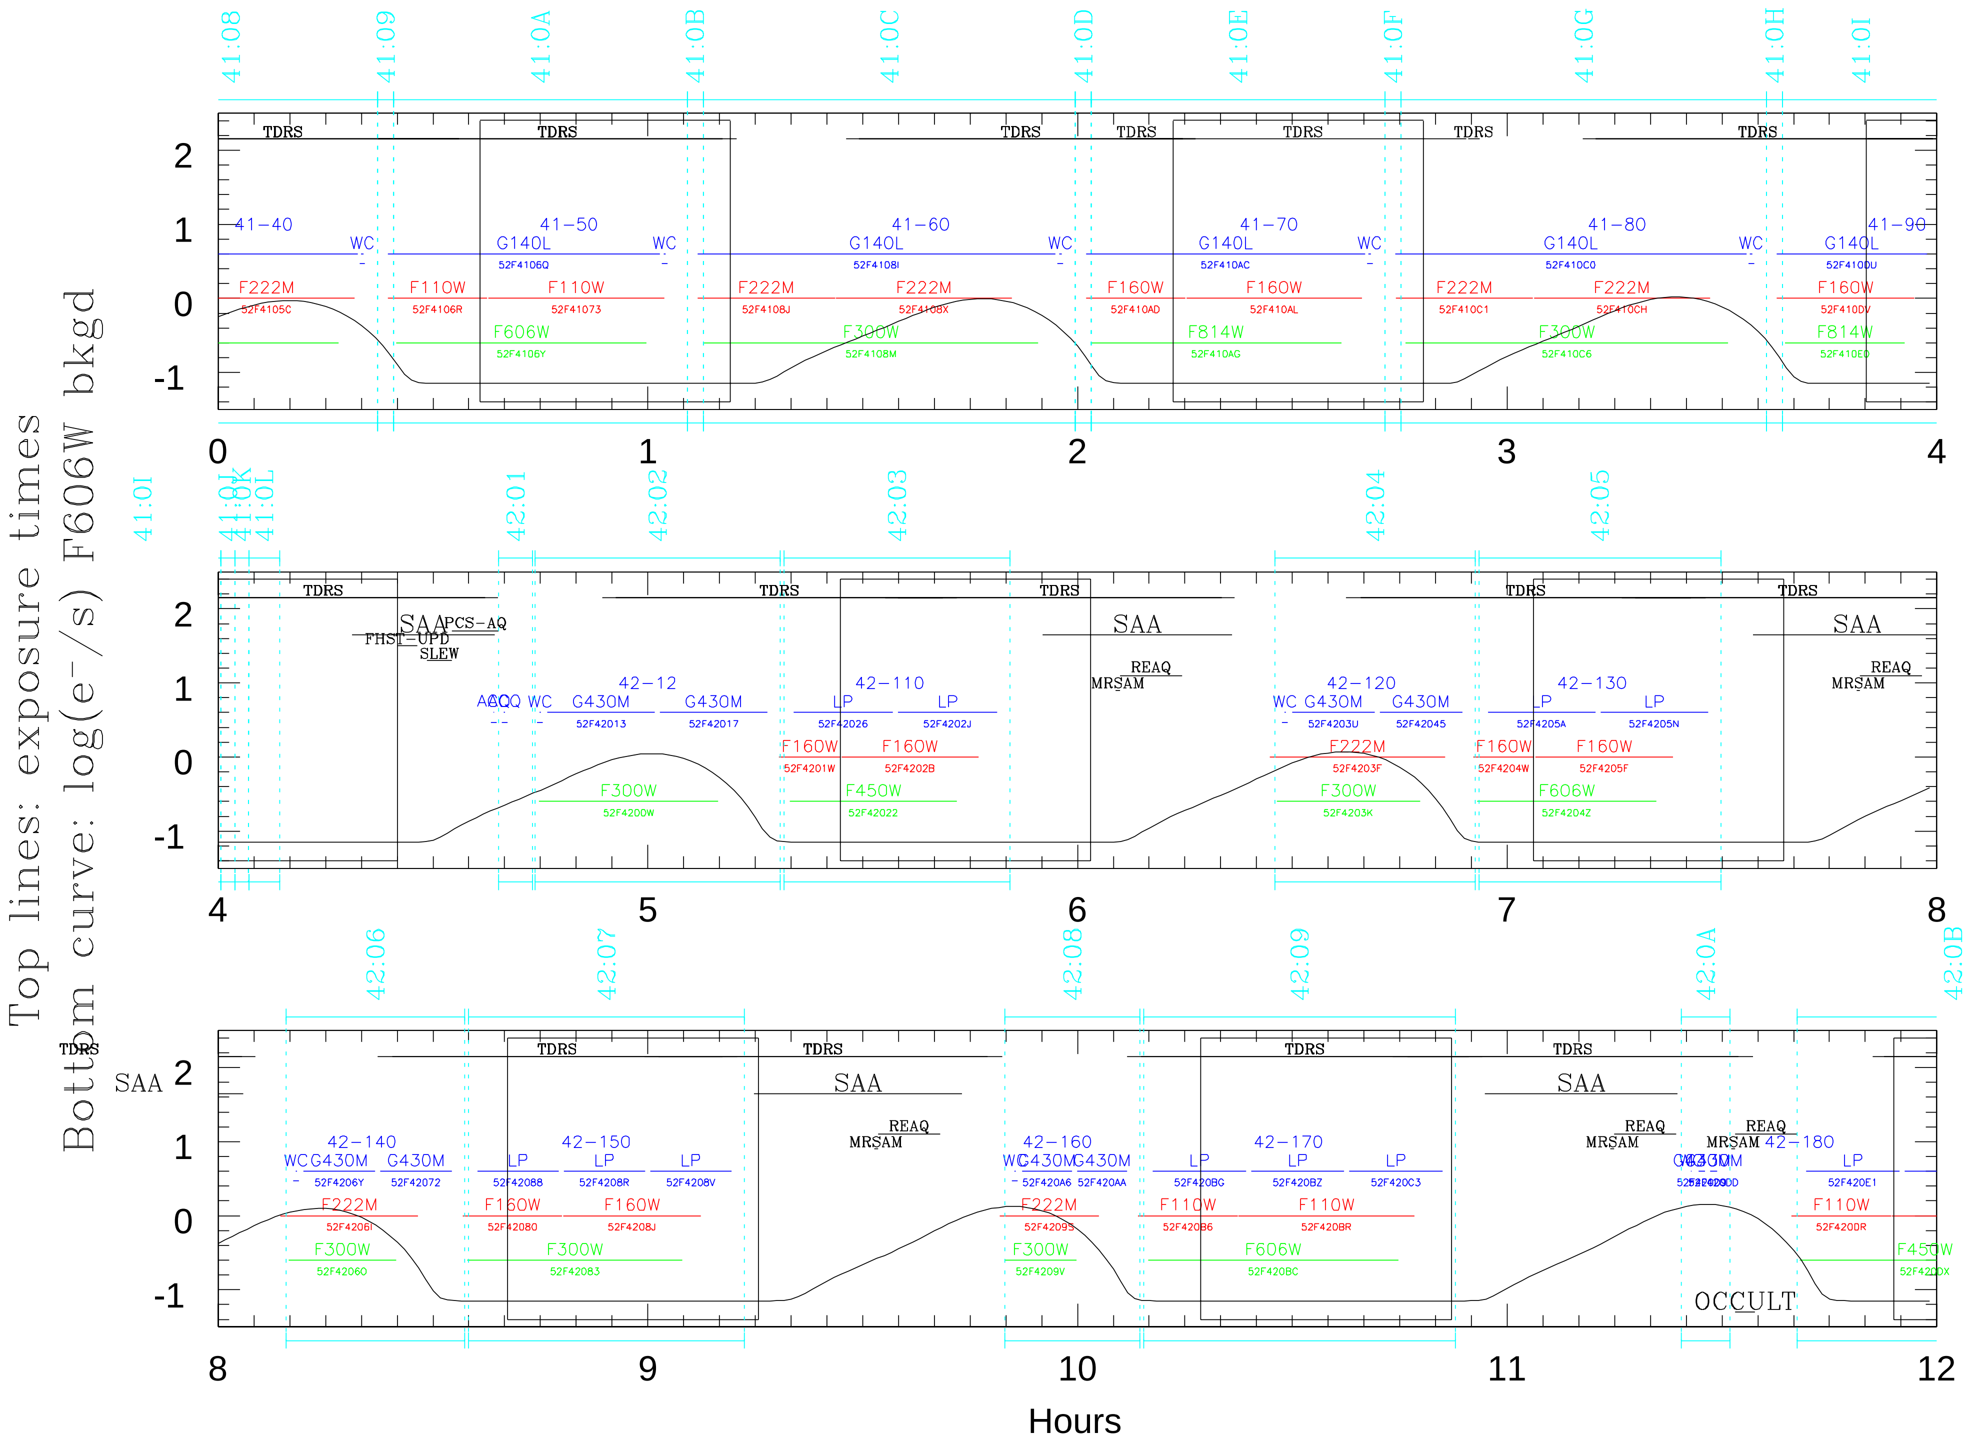
Day 279 = October 6



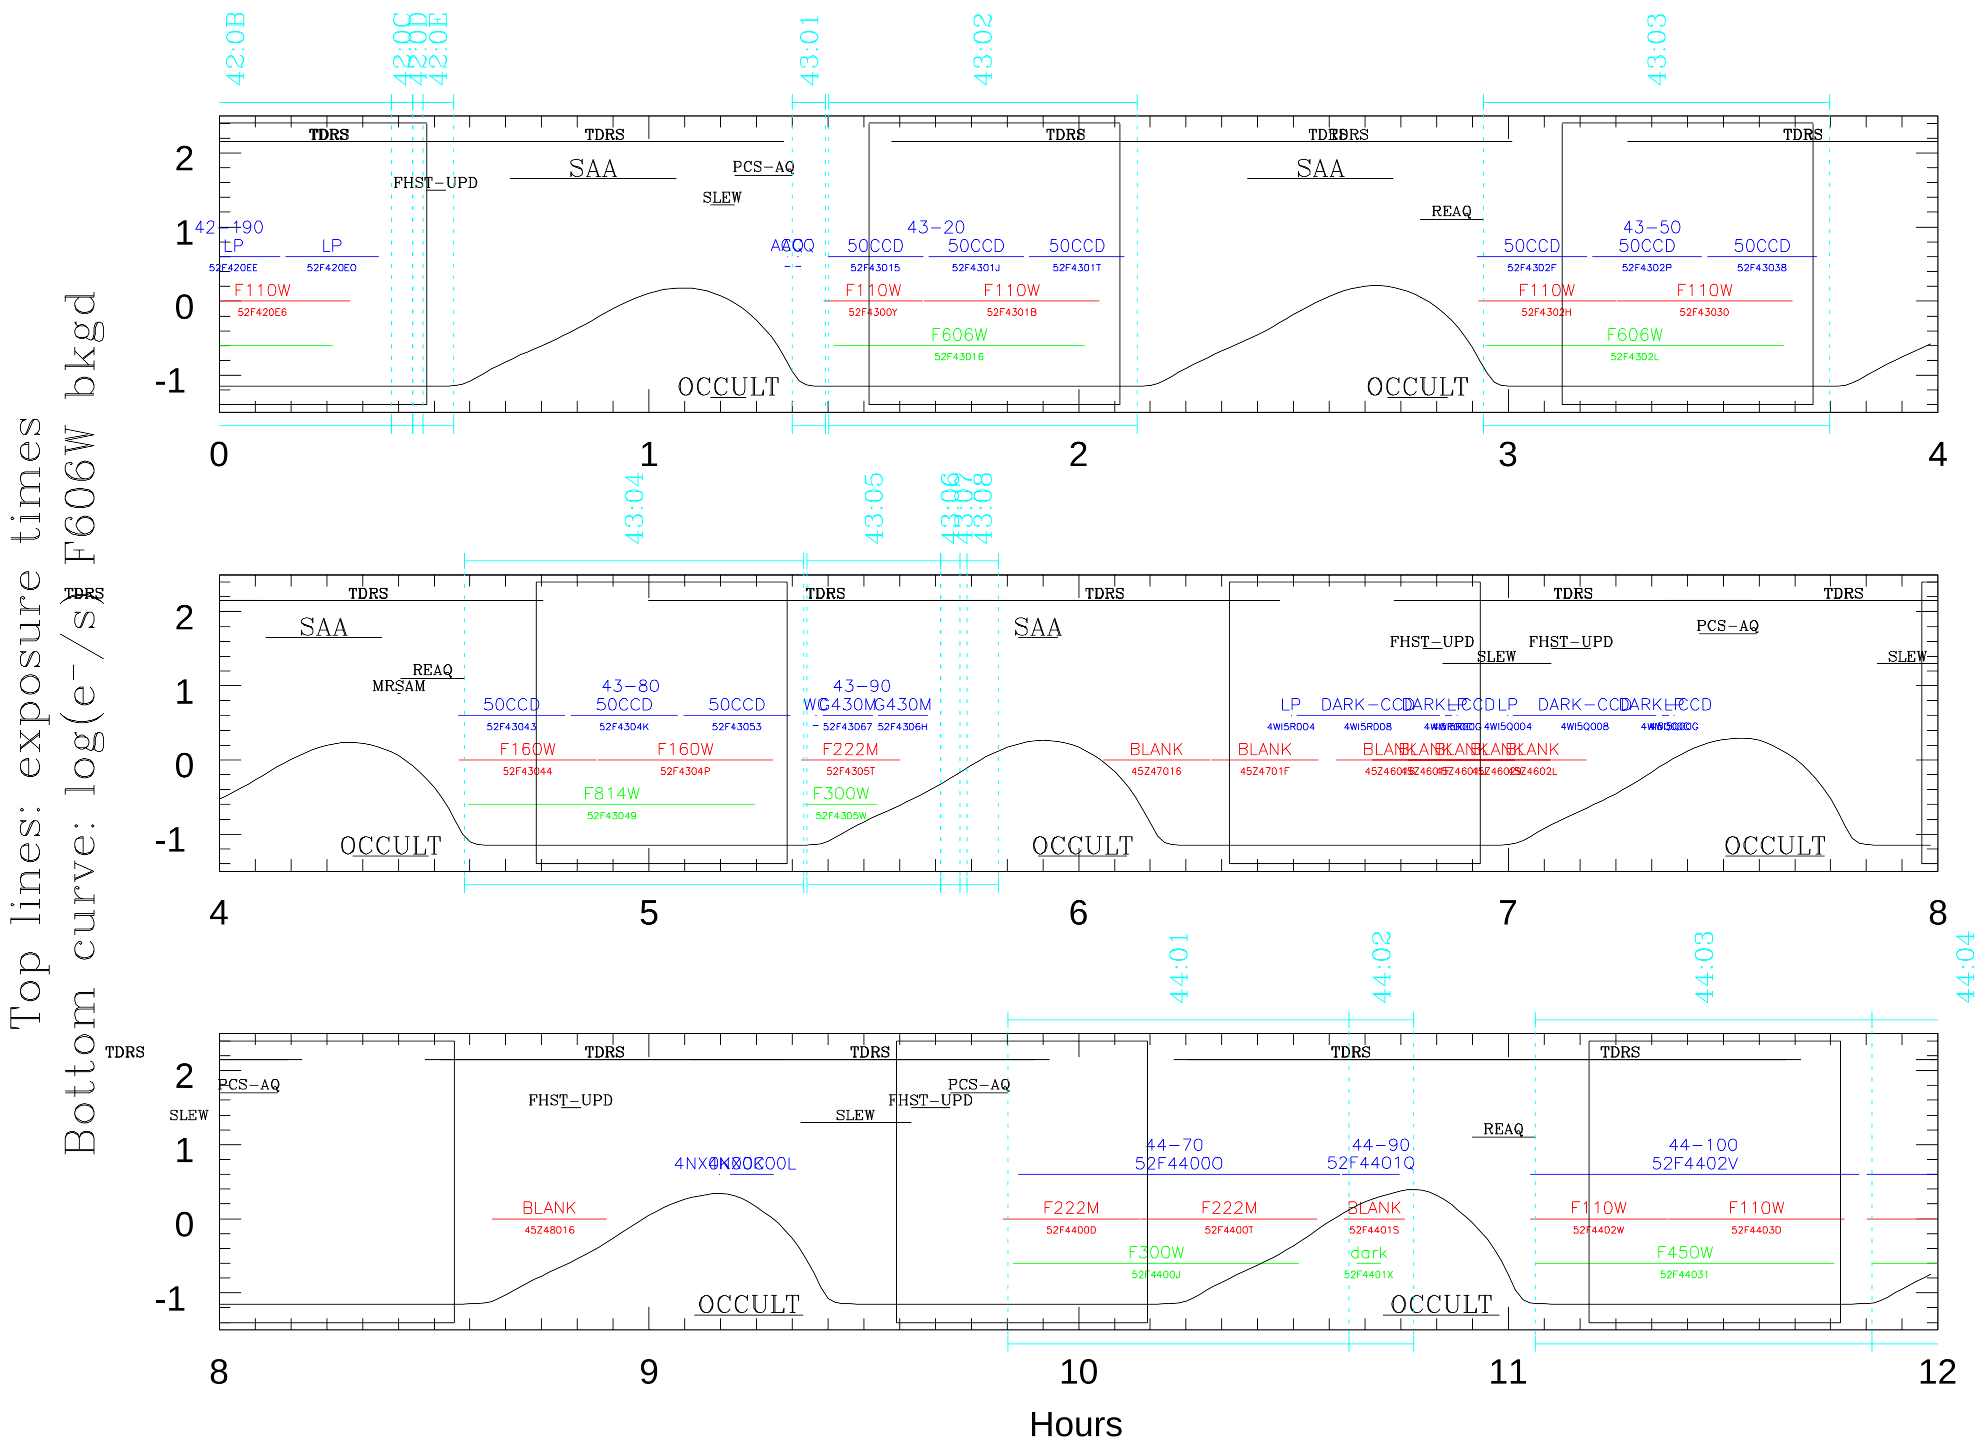
Day 279.5 = October 6



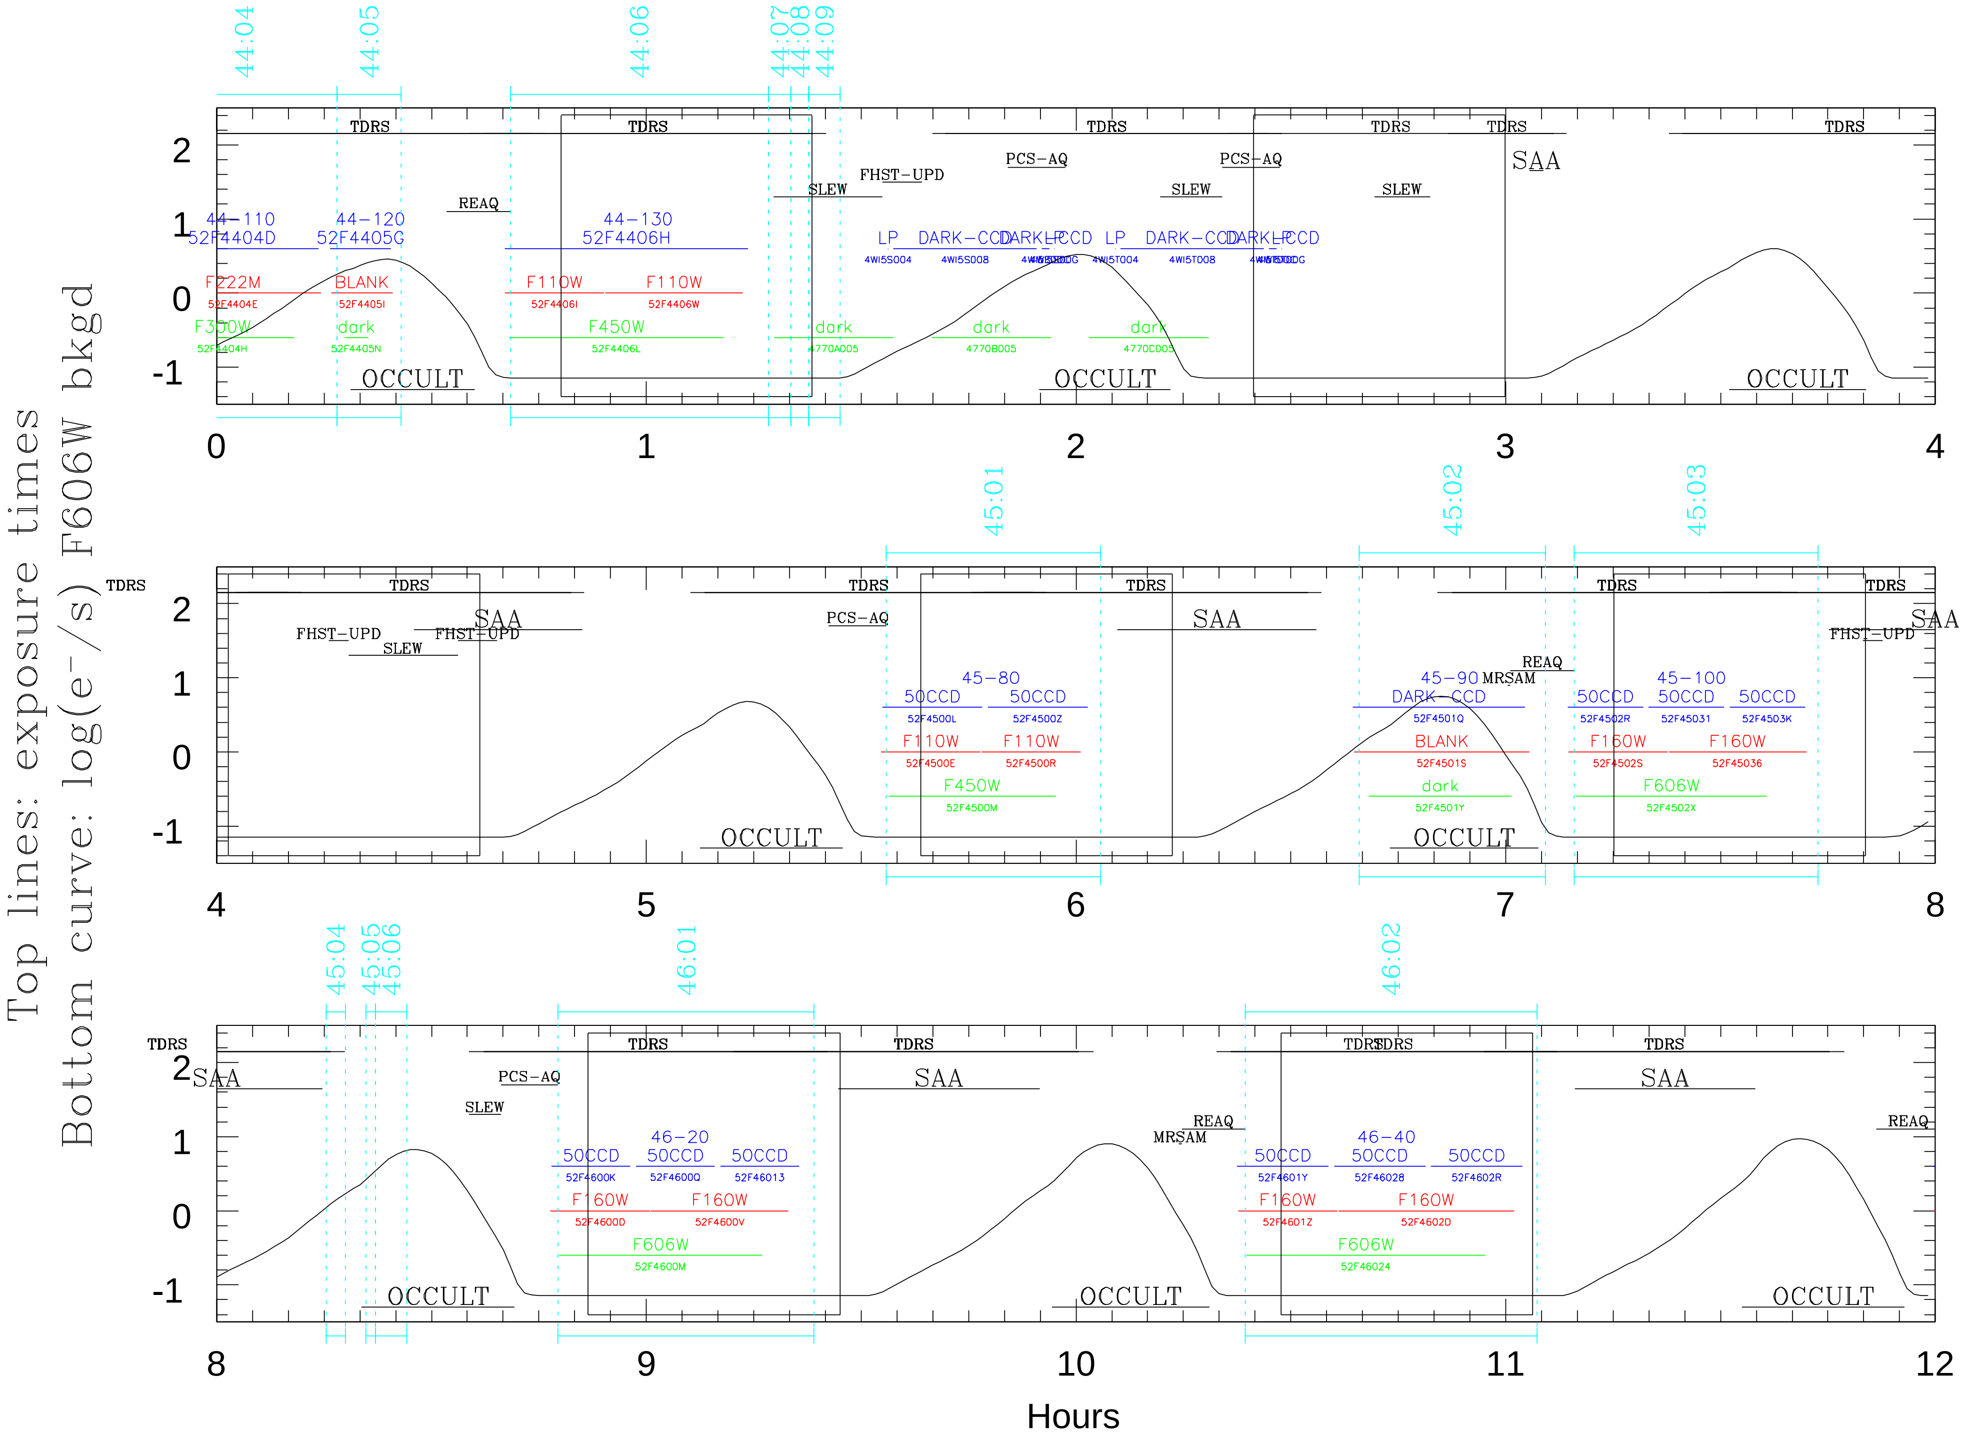
Day 280 = October 7



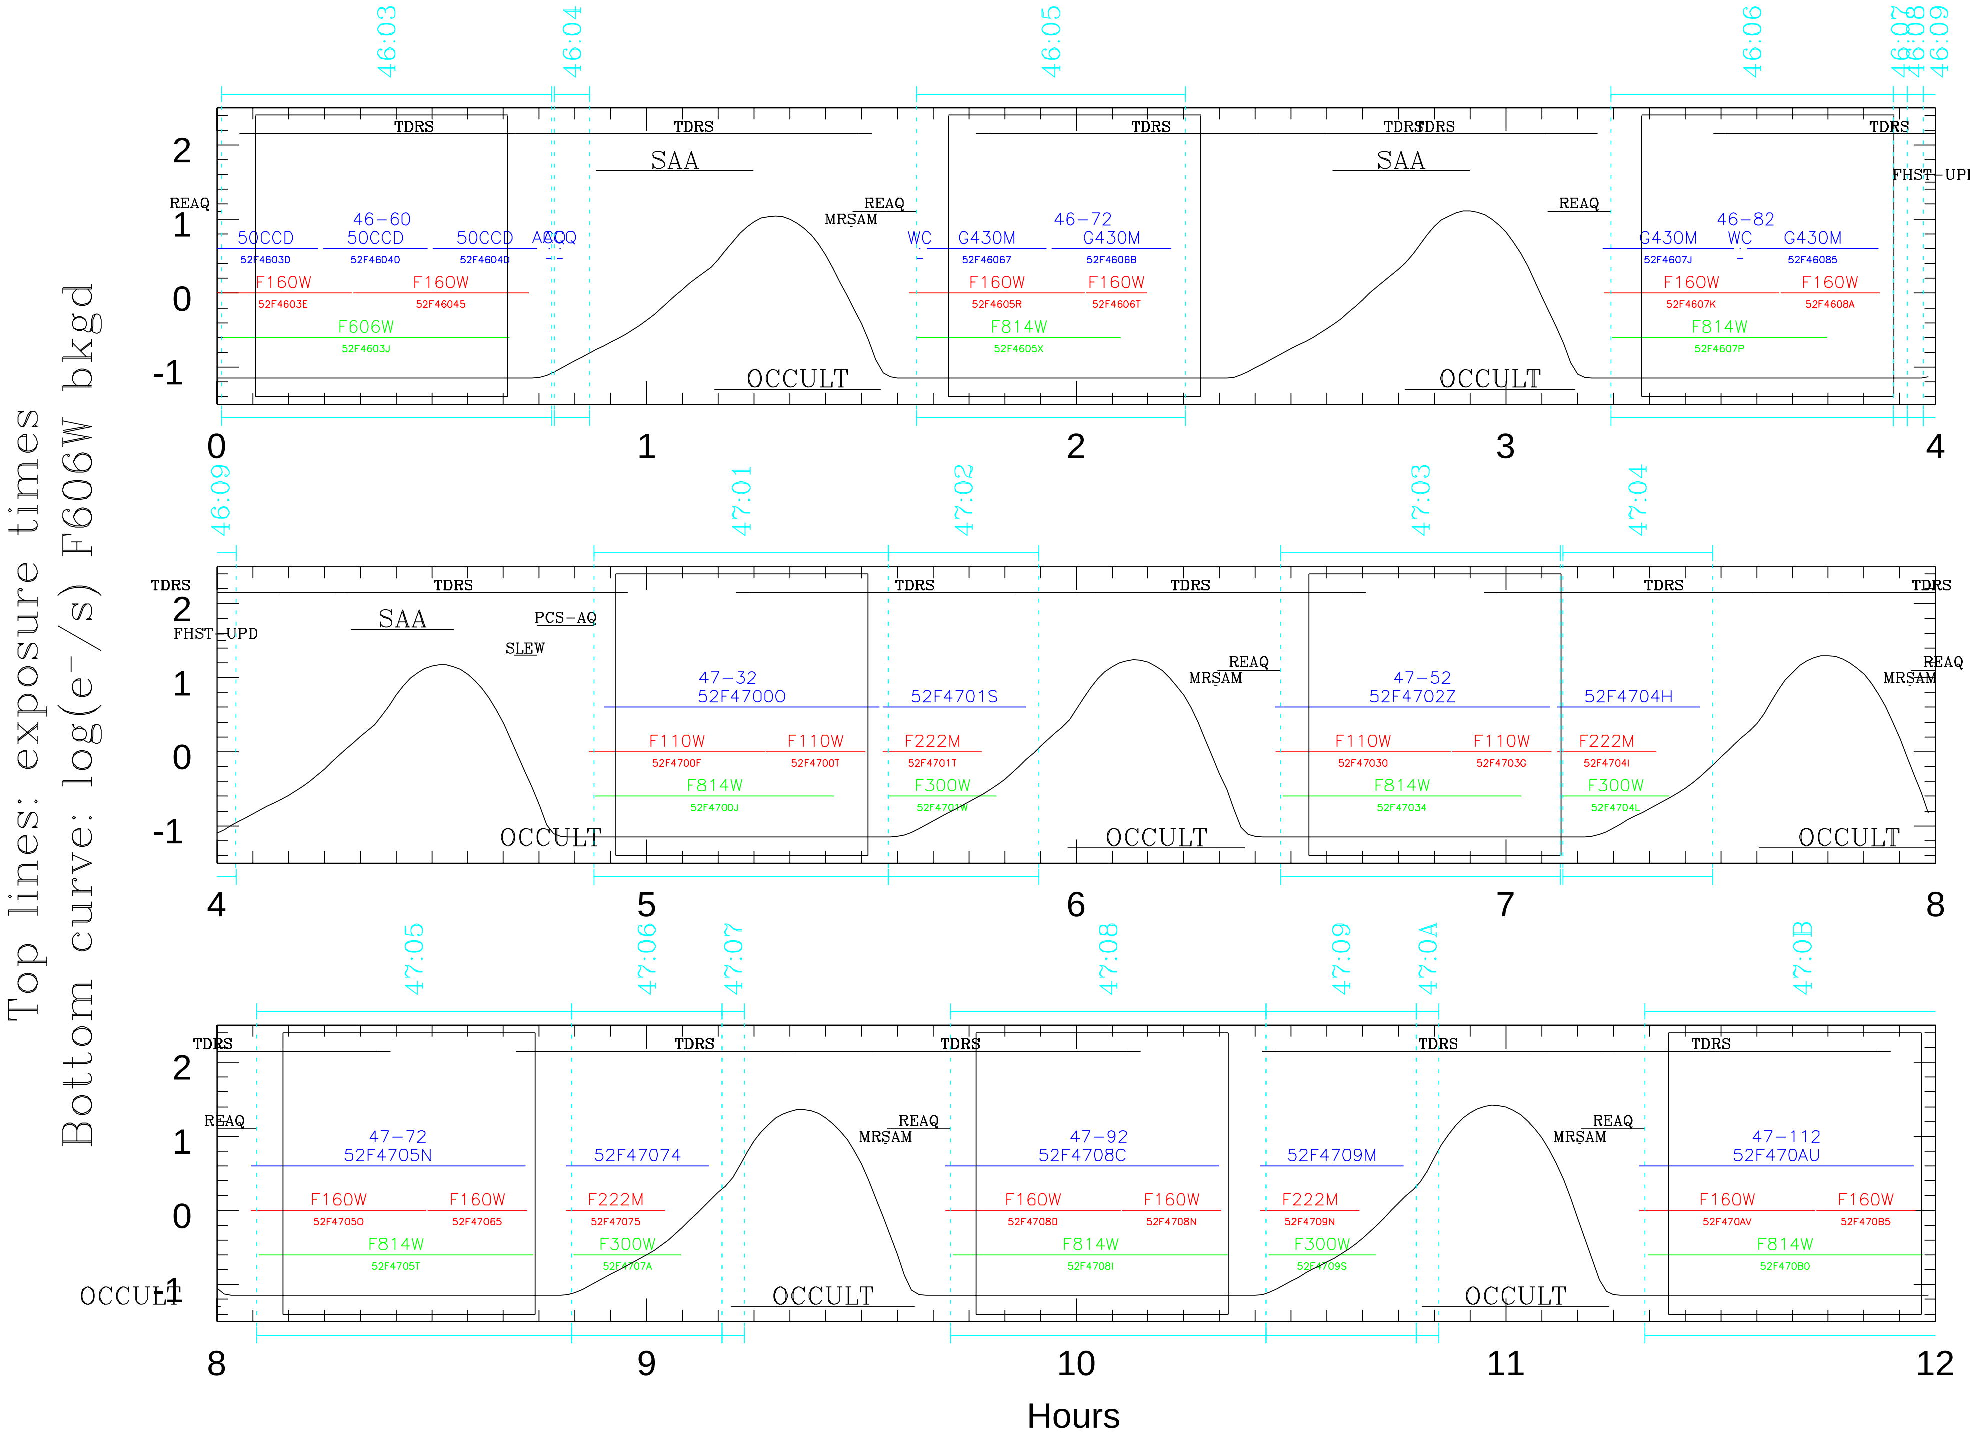
Day 280.5 = October 7



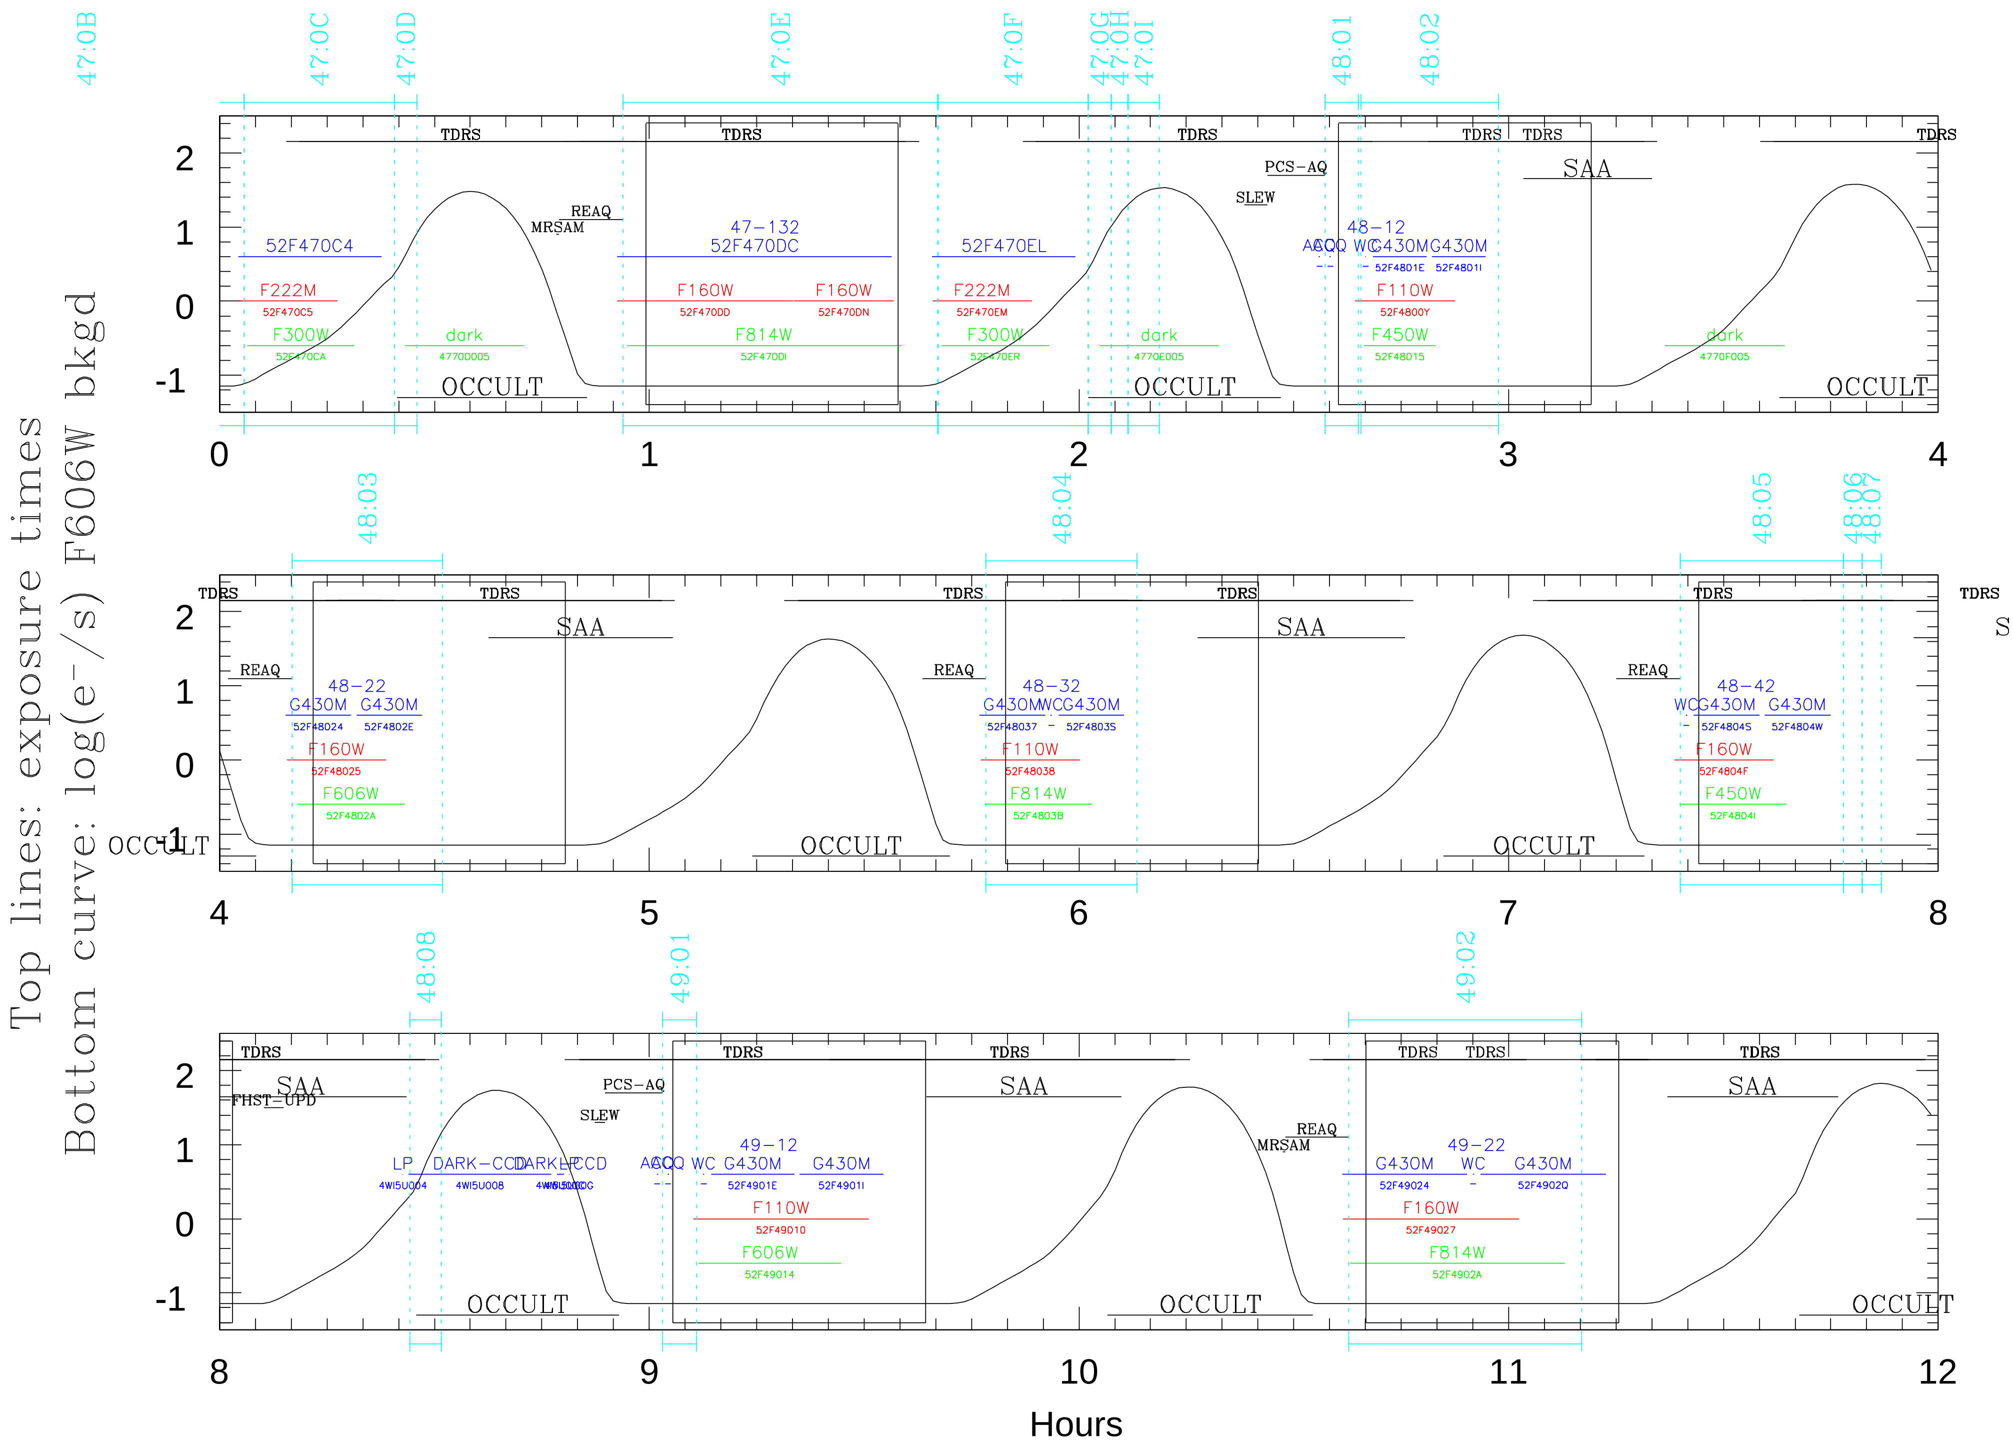
Day 281 = October 8



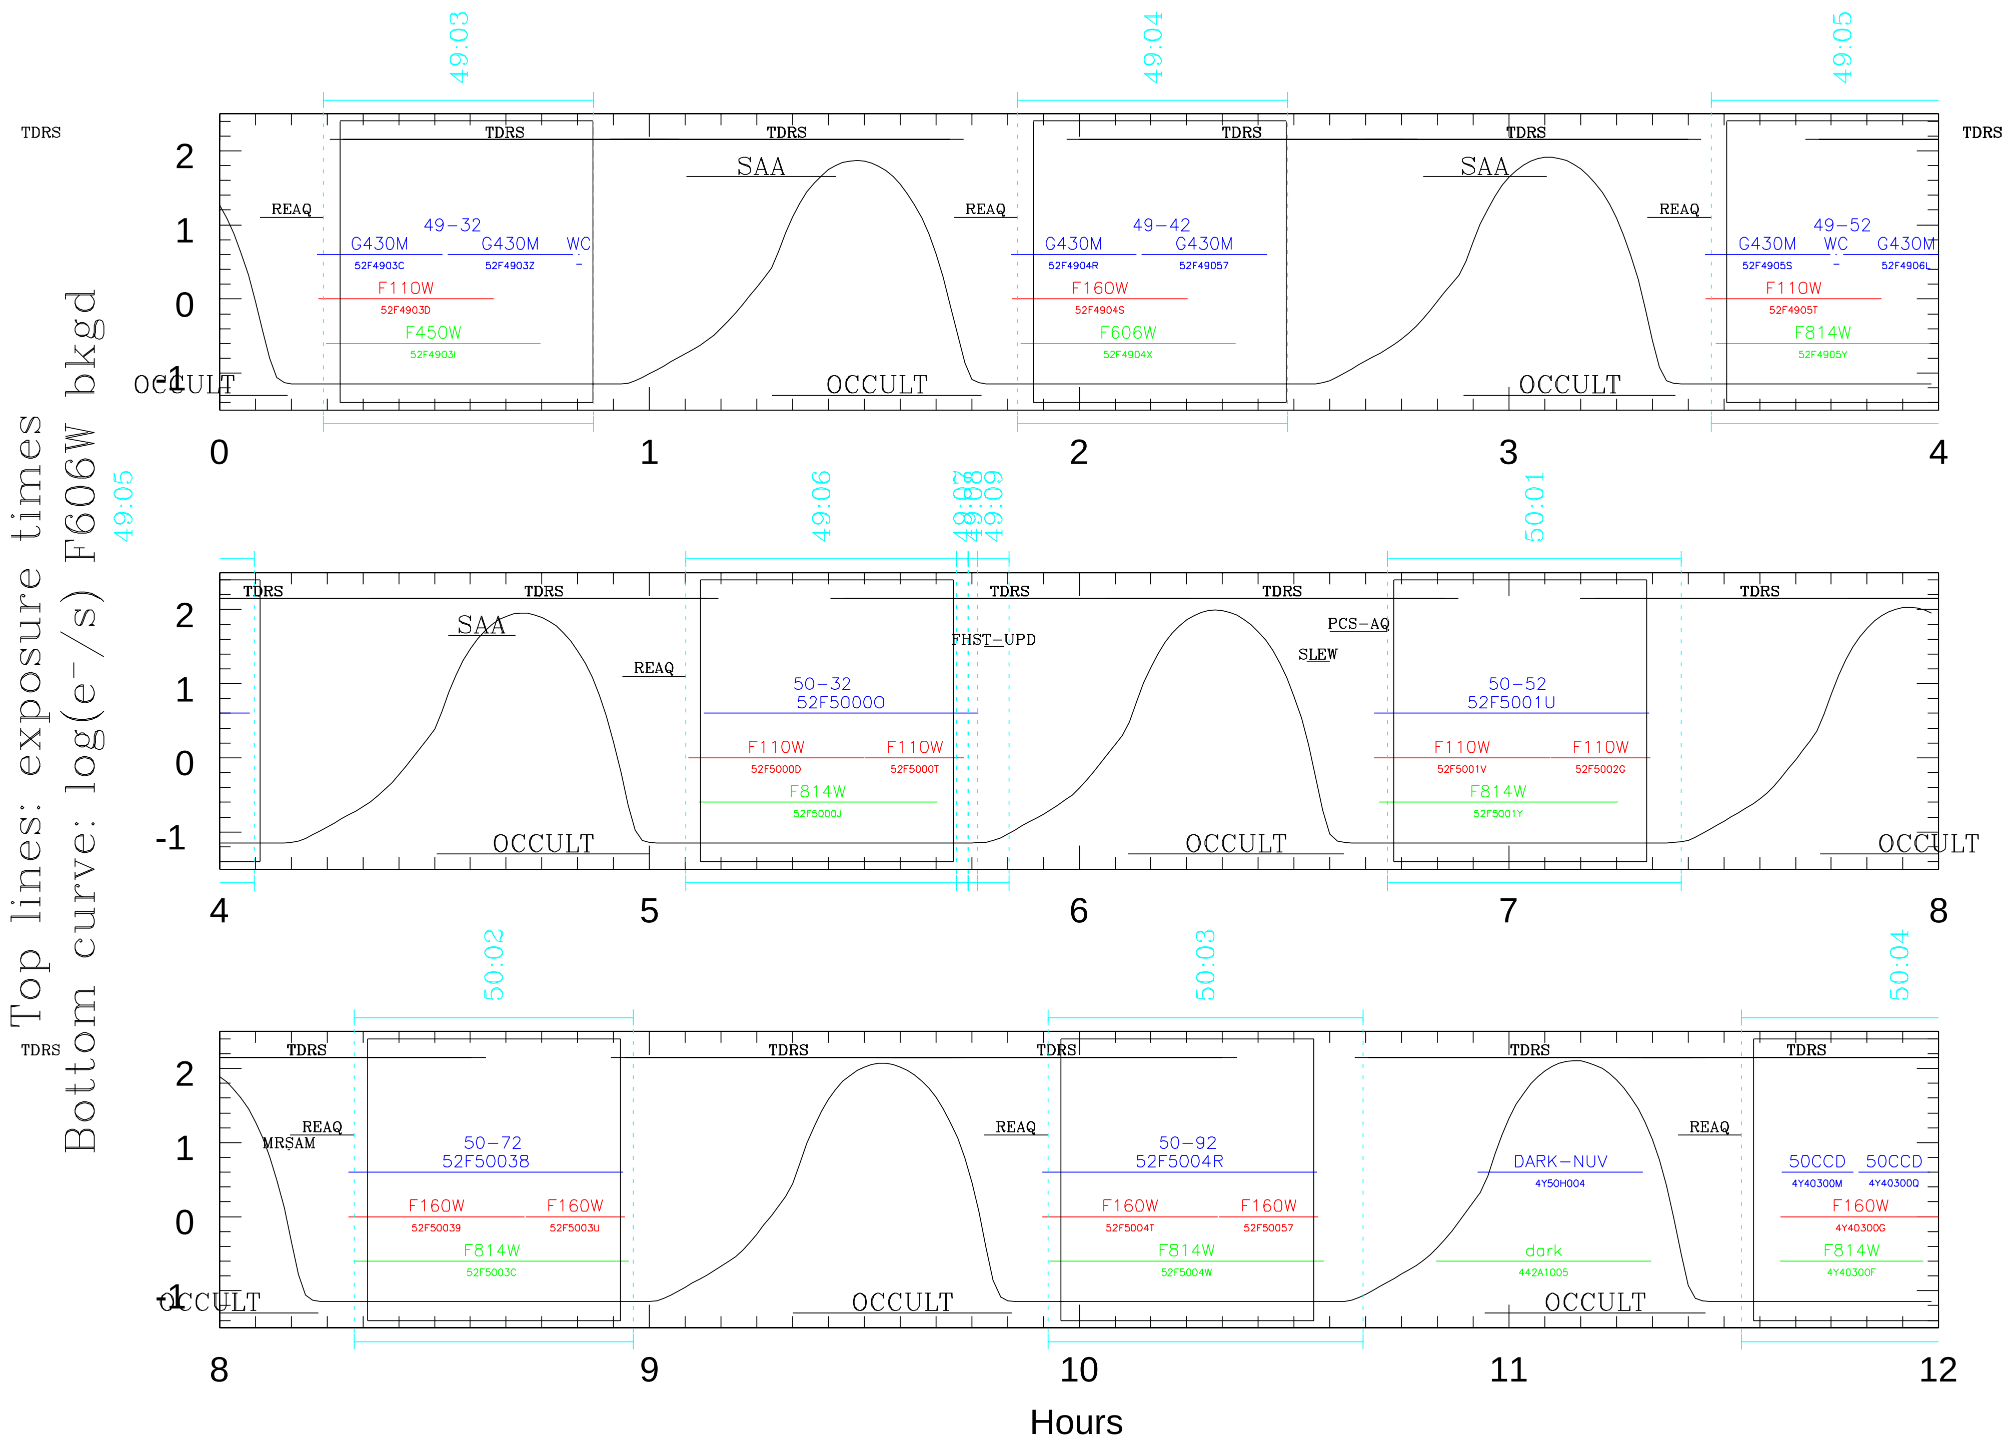
Day 281.5 = October 8



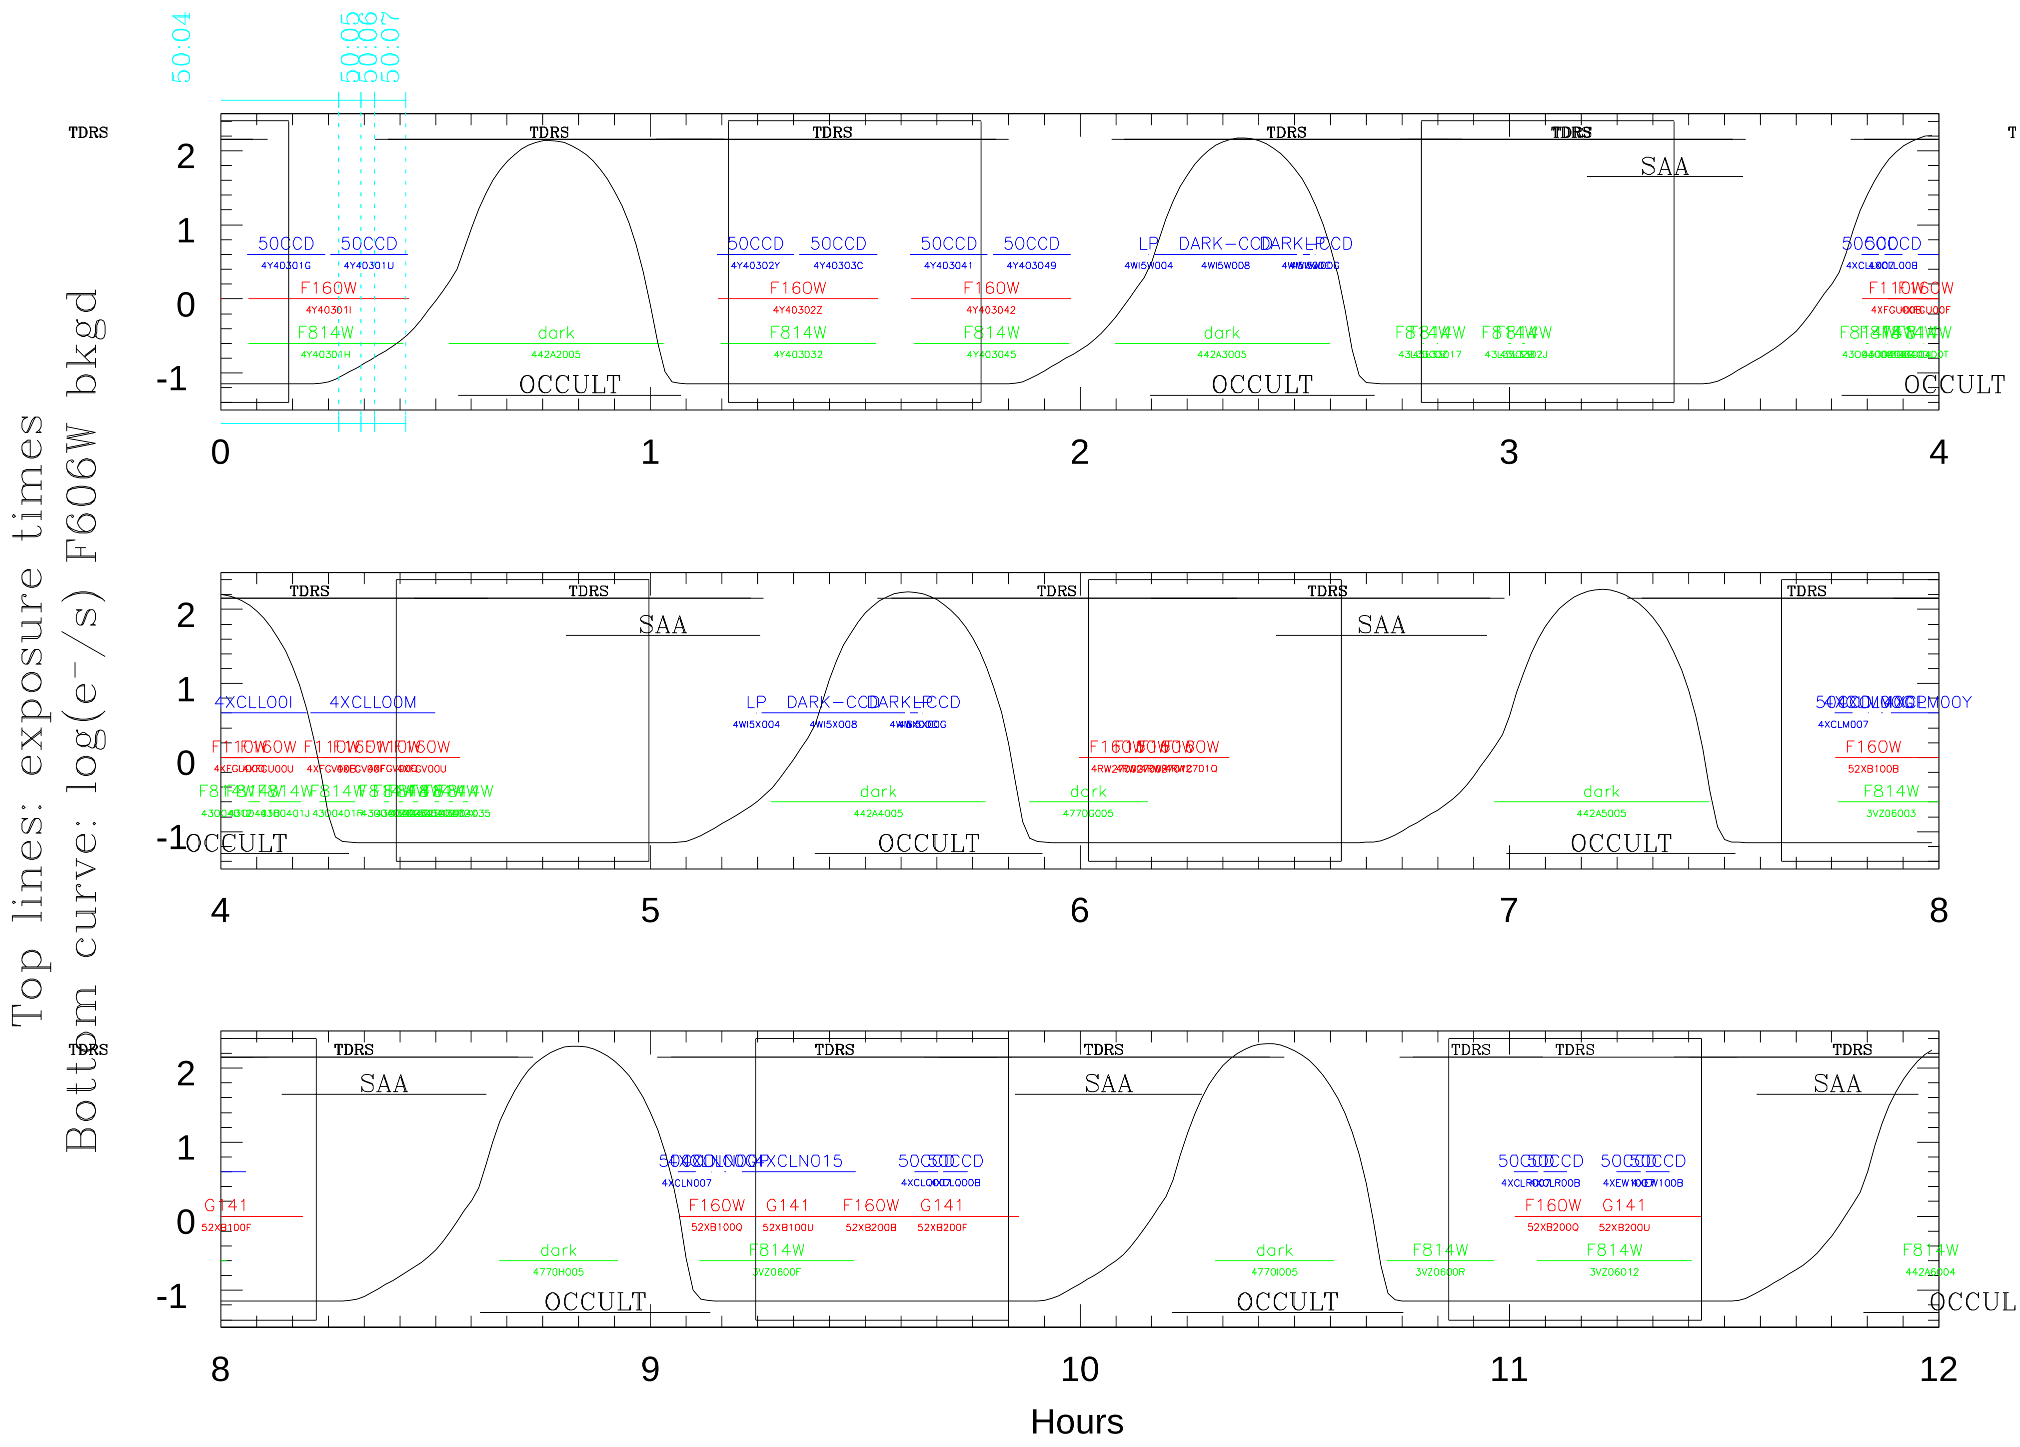
Day 282 = October 9



Day 282.5 = October 9



Day 283 = October 10



STIS Observing Log

Notes:

- This table was last updated: Tue Nov 3 14:55:58 EST 1998.
- The proposal **ID link** provides access to the relevant Phase 2 proposal information from the PRESTO website at STScI.
- The source of the **DQSKY** values are an iraf.stsdas.stis.iterstat mean DN/S after 10 iterations of 5 sigma median clipping of the original HST pipeline products, rootname_xxxxx, where xxxxx is:
  - 50CCD, g430m, and flanking fields: cr[[100:1000,100:1000]
  - F28X50LP: cr[[50:1000,250:775]
  - All datatypes from NUVMAMA: flt[sci,1][*,*]
  - FUV data and psfs: tbd

WFPC2 Observing Logs

Two logs are available:

- Master Log.
- Pointing Log.

Master Log

Notes:

- This table was last updated: Tue Nov 21, 1998.
- The **proposal ID** is the proposal containing the observation. See the Phase 2 information for details.
- **Nominal RA, DEC** refer to the commanded position of the V1 axis of the satellite, as given in the Science Header file (.shh).
- **Nominal roll** refers to the commanded orientation of the V3 axis of the satellite, as given in the Science Header file.
- **Included?** lists the chips (1,2,3 and/or 4) that were included in the Version 1 images; "yes" means all chips were included, "no" means none was.
- Each **Data quality** note is preceded by the chip(s) it refers to, in square brackets. No number means that the comment refers to all chips. Bias jumps and scattered Earth light were removed by subtraction of a median-filtered background before the images were used in the Version 1 combination.

NICMOS Observing Log

Logfile for the Hubble Deep Field South NICMOS observations. This listing contains basic information about the datasets, as well as a few useful "derived quantities" (e.g. an approximate measure of sky brightness, useful for screening out data with high background levels), and comments based on a preliminary visual inspection.

Note: The images have been named in such a way as to make the names more useful.

Image naming convention: prefixNN_VV_LLL

```
prefix:  j   - F110W image HDF-S field
         h   - F160W image HDF-S field
         k   - F222M image HDF-S field
         drk - Dark image

NN:      Number of samples (Ns)

VV:      Visit number (5-50)

LLL:     Exposure logsheet line number
         from the proposal
```

The original suffixs have been retained. For each image there should be 6 files associated with it. They are:

- raw - raw image no calibration
- ima - pipeline calibrated individual reads
- cal - pipeline calibrated and crrej image
- spt - engineering telemetry
- jif - jitter image
- jit - jitter file

```
****************************************************************************************************
Image = Filename
Oldim = Original dataset name (in the archive)
UT_observed = Obs start time (DDD:HH:MM:SS 1998)
Daynum = Obs start time (UT decimal day)
Filt = Filter
Exp = Exposure time in seconds
Ns  = Number of samples
Sky = Mean "sky" background in DN/s
RMS = Sky rms in DN/s (excluding objects and vignetted region)
Xsh = X shift from reference image in pixels
Ysh = Y shift from reference image in pixels
Ori = rotation angle from reference image in degrees
Wt  = Weight used for final drizzled mosaic
USED = Image was used in final drizzled mosaic
A = Scattered light  -- Determined from plots of the first differences between imsets
B = SAA impacted (CR persistence) -- Flagged if occurred within 90min of SAA exit
(Check image rms for significance)
C = Moving objects
D = Large cosmic ray hits
E = Bars (horizontal)
F = Bands (vertical)
G = Quadrant bias jumps
Comments = Data quality comments (CR=giant cosmic ray, MO=moving object, Number
indicates in which read it occurred)

STIS Flanking Fields Observing Log

Notes:

- This table was last updated: Tue Nov 3 14:55:58 EST 1998.
- The proposal **ID link** provides access to the relevant Phase 2 proposal information from the PRESTO website at STScI.
- The source of the **DQSKY** values are an iraf.stsdas.xstis.iterstat mean DN/S after 10 iterations of 5 sigma median clipping of the original HST pipeline products, rootname_crj.fits[100:1000,100:1000].

WFPC2 Flanking Fields Observing Logs

Two logs are available:

- Pipeline Log.
- Data Quality Log.

Pipeline Log

Notes:

- This table was last updated: Tue Nov 22, 1998.
- The **proposal ID** is the proposal containing the observation. See the Phase 2 information for details.
- Different fields are separeted by blank lines.

Data Quality Log

Notes:

- This table was last updated: Tue Nov 22, 1998.
- The **proposal ID** is the proposal containing the observation. See the Phase 2 information for details.
- **Charge traps and bad columns** are indicated by the following numbers:
  - [1]: column 527
  - [2]: column 337
  - [3]: columns 251+397
  - [4]: column 441
- **time_dq** is not filled in until DQ has been performed.
- **ds** stands for "diffraction spikes".
- Different fields are separeted by blank lines.

NICMOS Flanking Fields Observing Log

Logfile for the Hubble Deep Field South NICMOS Flanking Field observations. This listing contains basic information about the datasets, as well as a few useful "derived quantities" (e.g. an approximate measure of sky brightness, useful for screening out data with high background levels), and comments based on a preliminary visual inspection.

Note: The images have been named in such a way as to make the names more useful.

Image naming convention: prefixNN_VV_LLL

```
prefix: flnk - flanking field

NN:     flanking field ID (note that ff10 and ff11 are
        the same field)

VV:     not used

LLL:    Exposure logsheet line number
        from the proposal
```

The original suffixes have been retained. For each image there should be 6 files associated with it. They are:

- raw - raw image no calibration
- ima - pipeline calibrated individual reads
- cal - pipeline calibrated and crrej image
- spt - engineering telemetry
- jif - jitter image
- jit - jitter file

```
*********************************************************************************************************
Image = Filename
Oldim = Original dataset name (in the archive)
UT_observed = Obs start time (DDD:HH:MM:SS 1998)
Daynum = Obs start time (UT decimal day)
Filt = Filter
Exp = Exposure time in seconds
Ns  = Number of samples
Sky = Mean "sky" background in DN/s
RMS = Sky rms in DN/s (excluding objects and vignetted region)
Xsh = X shift from reference image in pixels
Ysh = Y shift from reference image in pixels
Ori = rotation angle from reference image in degrees
Wt  = Weight used for final drizzled mosaic
USED = Image was used in final drizzled mosaic
A = Scattered light  -- Determined from plots of the first differences between imsets
B = SAA impacted (CR persistence) -- Flagged if occurred within 90min of SAA exit
(Check image rms for significance)
C = Moving objects
D = Large cosmic ray hits
E = Bars (horizontal)
F = Bands (vertical)
G = Quadrant bias jumps
Comments = Data quality comments (CR=giant cosmic ray, MO=moving object, Number
indicates in which read it occurred)
*********************************************************************************************************

SAA Crossing Table

The table below contains info on the passage of HST thru the South Atlantic Anomaly (SAA) during the HDF-S Campaign. Some observations may have been adversly affected by this. The table columns are:

- column 1: time of SAA entering
- column 2: time of SAA exit
- column 3: time in the SAA

The times for **enter** and **exit** are given in the format of decimal day number (i.e. day+hour/24+min/(24*60)+sec/(24*3600)); **timein** is given in minutes.

This table was last modified on Thu 13:21:16 08-Oct-98.

STIS Data Reduction / Technical Issues

Check the page with warnings and advisories before making any use of the data.

Information is available about the following topics:

STIS UV echelle spectroscopy

Description of data products

Follow this link for a legend of the file names for the final reprocessed data. The following are the main characteristics of the final data products for the STIS E230M echelle mode data:

```
Total exposure time: 151074 sec
Mean background level: 9.57e-4 cts/s/pixel

Wavelength       Continuum S/N
2300-2600A:      1.5 per pixel
2700-3100A:      4   per pixel
```

Observations

The HDF-S QSO J2233-606 was observed with the STIS E230M echelle mode for a total of 151074 sec (42.6 hours). In this mode, STIS produces a spectrum covering near-UV wavelengths from 2275 to 3118 Anstroms. The spectrum is dispersed across 24 orders at a resolution R = 30000 per two pixels. The QSO was observed through the five separate 0.2x0.2" FP-SPLIT apertures. The five apertures are displaced from each other to allow a displacement of the spectrum on the detector, thus allowing for better flat-fielding accuracy. The telescope was pointed so that the spectrum shifts were largely confined to the wavelength dimension.

In most cases, target acquisitions were done without peaking up on the QSO. The standard CCD target acquisition acquires targets to an accuracy of better than 0.01 arcsec, which is 5% of the slit width. Typical thermal drifts over a typical 45 minute exposure are expected to be less than 0.1 pixels. Frequent calibration lamp observations insure that the wavelength scale is accurately calibrated. Because the observations were pointed near the pole of the HST orbit, the change in velocity of HST during an exposure was no more than 5 km/s. On-board processing corrects for this shift to a precision of 5 km/s in this observing mode.

Data reduction

The data reduction for the STIS E230M echelle data consisted of the following steps:

- 1. Flatfielding.
- 2. Wavelength correction.
- 3. Background fitting.
- 4. One-dimensional spectral extraction.
- 5. Flux calibration.
- 6. Weighted combination.

1. Flatfielding

The spectrum was flatfielded using a preliminary NUV flat derived from internal calibration lamp observations. This flat has been verified on observations of spectrophotometric standards. The flatfielding was carried out by the standard STSDAS "calstis" pipeline. The normal "Doppler smoothing" option was omitted during the pipeline processing. This is not expected to degrade the data, due to the small on-board doppler correction.

2. Wavelength correction

Wavelength correction was carried out via standard procedures in calstis, using contemporaneous observations of the internal calibration lamp. The wavelength accuracy for this observing mode was verified using archival STIS observations of the spectrophotometric standard star BD +28 4211, which was observed with STIS both with the 0.2x0.2" FP-SPLIT aperture and with the more standard 0.2x0.2" single aperture. Wavelengths for narrow interstellar MgII absorption features agreed to within 0.03 Angstroms (3 km/s). The observations of this star were also compared to high-resolution IUE observations. The mean shift relative to three IUE observations was -0.08 +- 0.07 Angstroms.

Comparison with the UCLES optical spectrum of the QSO (Outram et al. 198) shows good agreement. The radial velocities of the higher-order Lyman series lines agree to within 10 km/s with those measured for the Lyman alpha line in the UCLES spectrum.

3. Background fitting

The mean background in the STIS exposures is very low (9.6x10^-4 cts/s), and is almost entirely due to phosphorescent emission from the detector window. The mean background level varies with time, and the time dependence varies with position across the detector. To subtract the background from each exposure, a low-order spline fit was performed using pixels in the inter-order regions. This fit was subtracted from the data prior to extracting the one-dimensional spectra. The smooth fitted background level was used in the computation of the errors.

4. One-dimensional spectral extraction

The spectrum was extracted using a modified version of the STSDAS stis.x1d task. This program finds the position of the orders via cross-correlation. The task was modified to reject orders with low S/N and apply to the whole spectral extraction table a global shift that is determined from the orders with high S/N. Typically about 10 orders were used to find the position of the spectrum, and the rms of the measured shifts of these 10 orders was less than 0.15 pixels. After this centroiding step, the spectrum was extracted along a "trace," determined from observations of standard stars. The spectral extraction box was 3 pixels wide. At each wavelength, pixels within this extraction box were summed together with uniform weights. The S/N of the final spectrum could possibly be improved by extracting with "optimal" weights.

5. Flux calibration

Conversion of counts to flux was also carried out in the x1d task. Fluxes were corrected for the wavelength-dependent throughput of the 0.2x0.2" aperture, and for the light lost outside the extraction box, using the standard values in the APT and PCT reference files.

6. Weighted combination

At the end of one-dimensional extraction, the spectrum consists of 1656 separate pieces, which need to be summed together in a way that maximizes the signal-to-noise ratio of the final spectrum. This "optimal" combination was carried out using a prototype version of the STSDAS routine "splice." This program uses weighting arrays that specify the weight to be used when averaging fluxes from orders that overlap in wavelength. We chose to weight the flux in each order by the (S/N)^2 vs. pixel, as determined from a smooth fit to the continuum; prefering not to have the weights vary sharply around the edges of absorption lines. The first and last 30 pixels of each order were masked during the combination.

This process was iterative. The individual extracted orders were first combined through a simple average in regions of wavelength overlap; the result was an initial estimate of the total echelle spectrum. This estimate was then fit with a cubic spline to produce a continuum estimate. The continuum was then interpolated onto the wavelength array of each order in each exposure, and converted into counts (through multiplication by exposure time and sensitivity). A weighting array for each order was then computed as

```
w = (continuum counts)^2 / (continuum counts + background counts).
```

Arrays of wavelength, flux, statistical errors, and weight for all orders of all frames were then combined by splice into a second iteration of the total echelle spectrum. The process was then iterated once more (continuum estimation --> weight determination --> splice combination) to produce the third and final iteration of the total echelle spectrum.

STIS UV low-resolution spectroscopy

Description of data products G140L

Follow this link for a legend of the file names for the final reprocessed data. The following are the main characteristics of the final data products for the STIS G140L data:

```
Total exposure time   : 18480 sec
Mean background level :   cts/s/pixel (excluding airglow lines)

Wavelength      Continuum S/N
1167-1590A:     >10 per pixel in the continuum, peaking at ~ 18 at 1320A
```

Observations G140L

The HDF-S QSO J2233-606 was observed with the STIS G140L first order mode for a total of 18480 sec (5.1 hours). In this mode, STIS produces a spectrum covering near-UV wavelengths from 1126 to 1721 Angstroms at a resolution of ~1100. The 52x0.2" aperture was used for all observations.

In most cases, target acquisitions were done without peaking up on the QSO. The standard CCD target acquisition acquires targets to an accuracy of better than 0.01 arcsec, which is 5% of the slit width. Typical thermal drifts over a mean 38 minute exposure are expected to be negligible. Frequent calibration lamp observations insure that the wavelength scale is accurately calibrated.

Because the observations were pointed near the pole of the HST orbit, the change in velocity of HST during an exposure was no more than 5 km/s. On-board processing corrects for this shift to a precision of 5 km/s in this observing mode. The final wavelength scale has been reduced to the heliocentric frame.

Note that the final spectrum shows the residual effect of the presence of geocoronal Ly-alpha over the range ~1210-1220 Angstroms and, to a lesser extent, the effect of OI over the range 1301-1310 Angstroms. Airglow emission from the OI] 1356 Angstrom line is weak and almost completely absent in the final spectrum.

Data reduction G140L

The data reduction for the STIS G140L data consisted of the following steps:

- 1. Flatfielding.
- 2. Wavelength correction.
- 3. Background fitting.
- 4. One-dimensional spectral extraction.
- 5. Flux calibration.
- 6. Weighted combination.

1. Flatfielding

The spectrum was flatfielded using a preliminary FUV flat derived from internal calibration lamp observations. This flat has been verified on observations of spectrophotometric standards. The flatfielding was carried out by the standard STSDAS "calstis" pipeline. The normal "Doppler smoothing" option was omitted during the pipeline processing. This is not expected to degrade the data, due to the small on-board doppler correction.

2. Wavelength correction

Wavelength correction was carried out via standard procedures in calstis, using contemporaneous observations of the internal calibration lamp.

3. Background

The mean background in the STIS exposures is extremely low and is almost entirely due to the detector itself. The mean background level varies with time, and shows a temperature dependence. Background counts vary with position across the detector and vary from a mean of ~6x10^-5 ct/s/pixel near the "hot spot" centered close to pixel location (222,615), to ~1x10^5 ct/s/pixel at the long wavelength edge of the detector.

4. One-dimensional spectral extraction

The spectrum was extracted using the standard version of the STSDAS stis.x1d task. After preliminary testing, a spectral extraction box of 11 pixels in cross-dispersion width was found to better S/N that smaller boxes. This is larger than the boxes used in the G230L and E230M cases, but is consistent with the lower background in this detector. As the background is so weak with this detector/grating combination, we were unable to obtain a good two- dimensional fit. We therefore used the standard background measurement of the x1d task in which background regions either side of the spectrum are averaged and subtracted from each spectrum pixel. As the background is weak, we chose large background measurement regions than normal, offset by ten pixels either side of the center of the spectrum, and extending for 280 pixels further away. The background box size was limited to this size by the desire to use a similar background region size for all spectra. For three spectra (root names: o52f41040, o52f41050 and o52f41060) the spectra were offset towards the top of the detector, limiting the maximum region available for background measurement.

The spectral intensity was high enough to permit centring of the extraction box by the x1d task. After this centroiding step, the spectrum was extracted using a standard "trace" from the calibration database (the 1DT file). This trace corrects for instrument-induced distortions of the spectrum and is determined from observations of standard stars. At each wavelength, pixels within this extraction box were summed together with uniform weights. The S/N of the final spectrum could possibly be improved by extracting with "optimal" weights.

5. Flux calibration

Conversion of counts to flux was also carried out in the x1d task. Fluxes were corrected for the wavelength-dependent throughput of the 52x0.2" aperture, and for the light lost outside the extraction box, using the standard values in the APT and PCT reference files.

6. Weighted combination

At the end of one-dimensional extraction, we needed to combine the twelve separate exposures in a way that maximizes the signal-to-noise ratio of the final spectrum. This "optimal" combination was carried out using a prototype version of the STSDAS routine "splice." This program uses weighting arrays that specify the weight to be used when averaging fluxes from spectra that overlap in wavelength. We chose to weight the flux in each spectrum by the (S/N)^2 per pixel, smoothed over five pixels to reduce sharp variations in weighting value from pixel-to-pixel. No other corrections were made to the final weights.

Description of data products G230L

Follow this link for a legend of the file names for the final reprocessed data. The following are the main characteristics of the final data products for the STIS G230L data:

```
Total exposure time   : 18424 sec
Mean background level : 1.08e-3 cts/s/pixel (excluding airglow lines)

Wavelength      Continuum S/N
2200-2640A:     ~20 per pixel in the continuum
2700-2900A:     ~45 per pixel in the continuum
```

Observations G230L

The HDF-S QSO J2233-606 was observed with the STIS G230L first order mode for a total of 18424 sec (5.1 hours). In this mode, STIS produces a spectrum covering near-UV wavelengths from 1585 to 3173 Angstroms at a resolution of ~550. The 52x0.2" aperture was used for all observations.

In most cases, target acquisitions were done without peaking up on the QSO. The standard CCD target acquisition acquires targets to an accuracy of better than 0.01 arcsec, which is 5% of the slit width. Typical thermal drifts over a mean 25 minute exposure are expected to be negligible. Frequent calibration lamp observations insure that the wavelength scale is accurately calibrated.

Because the observations were pointed near the pole of the HST orbit, the change in velocity of HST during an exposure was no more than 5 km/s. On-board processing corrects for this shift to a precision of 5 km/s in this observing mode. The final wavelength scale has been reduced to the heliocentric frame.

Data reduction G230L

The data reduction for the STIS G230L data consisted of the following steps:

- 1. Flatfielding.
- 2. Wavelength correction.
- 3. Background fitting.
- 4. One-dimensional spectral extraction.
- 5. Flux calibration.
- 6. Weighted combination.

1. Flatfielding

The spectrum was flatfielded using a preliminary NUV flat derived from internal calibration lamp observations. This flat has been verified on observations of spectrophotometric standards. The flatfielding was carried out by the standard STSDAS "calstis" pipeline. The normal "Doppler smoothing" option was omitted during the pipeline processing. This is not expected to degrade the data, due to the small on-board doppler correction.

2. Wavelength correction

Wavelength correction was carried out via standard procedures in calstis, using contemporaneous observations of the internal calibration lamp.

3. Background fitting

The mean background in the STIS exposures is very low (~1x10^-3 cts/s/pixel), and is almost entirely due to phosphorescent emission from the detector window. The mean background level varies with time, and the time dependence varies with position across the detector. To subtract the background from each exposure, a low-order two-dimensional polynomial fit was performed to pixels at both sides of the spectrum. Each of the fit regions covered the whole width of the detector, and one hundred pixels perpendicular to the dispersion direction. This fit was subtracted from the data prior to extracting the one-dimensional spectra. As over 2.0x10^5 pixels were used in the fitting process, this is assumed to be a negigible source of error. Hence the error array from the original (gross) counts was carried through this process and used in the computation of the final errors due to the one-dimensional extraction.

4. One-dimensional spectral extraction

The spectrum was extracted using the standard version of the STSDAS stis.x1d task. After preliminary testing, a spectral extraction box of five pixels in the cross-dispersion direction was found to give a good compromise between extracted signal and error, resulting in a peak S/N. The spectrum was strong enough to permit centring of the extraction box by the x1d task. After this centroiding step, the spectrum was extracted using a standard "trace" from the calibration database (the 1DT file). This trace corrects for instrument- induced distortions of the spectrum and is determined from observations of standard stars. At each wavelength, pixels within this extraction box were summed together with uniform weights. The S/N of the final spectrum could possibly be improved by extracting with "optimal" weights, though our choice of a small extraction box probably comes close to an "optimal" result.

5. Flux calibration

Conversion of counts to flux was also carried out in the x1d task. Fluxes were corrected for the wavelength-dependent throughput of the 52x0.2" aperture, and for the light lost outside the extraction box, using the standard values in the APT and PCT reference files.

6. Weighted combination

At the end of one-dimensional extraction, we needed to combine the twelve separate exposures in a way that maximizes the signal-to-noise ratio of the final spectrum. This "optimal" combination was carried out using a prototype version of the STSDAS routine "splice". This program uses weighting arrays that specify the weight to be used when averaging fluxes from spectra that overlap in wavelength. We chose to weight the flux in each spectrum by the (S/N)^2 per pixel, smoothed over five pixels to reduce sharp variations in weighting value from pixel-to-pixel. A test using combined, unweighted, spectra shows that the use of smoothed weights does not affect the line profiles significantly.

As noted above in step 3, the errors carried through to the final one- dimensional extracted spectra are based on the counts prior to the two- dimensional background subtraction. Therefore no other corrections were made to the final weights.

STIS optical spectroscopy

Description of data products

Follow this link for a legend of the file names for the final reprocessed data.

The following are the main characteristics of the final data products for the STIS G430M data:

```
Wavelength coverage: 3025 A to 3565 A.
Total exposure time: 54,892 sec (~15.2 hrs)
                     (29,292 sec for cenwave=3165 A, and
                      25,600 sec for cenwave=3423 A)
Dispersion: 0.28 A/pix
Wavelength resolution: ~0.5 A
S/N ~5 to 15 per pixel.
```

Observations

The HDF-S QSO J2233-606 was observed with the STIS G430M first-order mode for a total of 57092 sec (15.2 hours) in 2 central wavelength settings. The first setting was centered at 3165A, covered the wavelength range 3025 A to 3305 A, and had a total exposure time of 29,292 sec. The second setting was centered at 3423 A, covered the wavelength range 3280 A to 3565 A, and had a total exposure time of 25,600 sec. The dispersion in this mode is 0.28 A/pix; the FWHM of the instrumental line profile is about 2 pixels, corresponding to a spectral resolution of 0.56 A. A 52X0.2 arcsec slit was used for all the observations.

Observations were taken with a CR-split of 2 to aid cosmic-ray rejection. The spectrum was also 'dithered' by about 2.5arcsec (50 pixels) in the cross-dispersion direction in order to be able to correct for the numerous hot-pixels in the data reduction stage. Frequent calibration lamp exposures were taken to ensure proper wavelength calibration. Since the observations were made near the pole of the HST-orbit, the change in the velocity of HST is less than 5 km/sec. Since the velocity resolution of the observations is about 50 km/sec, the smearing to to the change is the velocity of HST is not significant.

Follow this link for a listing of the individual datasets, including exposure times, that were used used to create the final combined spectra.

Data reduction

Data reduction steps:

- 1. Bias and dark subtraction and flagging of hot pixels
- 2. Cosmic ray rejection
- 3. Flatfielding
- 4. Wavelength correction
- 5. Background fitting
- 6. 1-d spectral extraction
- 7. Flux calibration
- 8. Weighted combination

Since the observations are readnoise dominated, special care was taken for the bias and dark subtractions. Weekly darks were specially made for the duration of the HDF-campaign, which were used for the dark subtraction of individual images. STIS CCD develops hot-pixels during the periods of successive 'annealing'. A master 'hot-pixel' mask was made using all the dark exposures taken during the campaign, which was used to 'flag' the hot pixels. A large fraction of the cosmic rays were rejected using the CR-split images.

Wavelength correction was carried out via standard procedures in calstis, using contemporaneous observations of the internal calibration lamp. Comparison with the UCLES optical spectrum of the QSO (Outram et al. 1998) shows agreement to 1/5th of the resolution element of the G430M spectrum.

The spectrum was extracted using a modified version of the STSDAS stis.x1d task. A profile of the spectrum was made in the cross dispersion direction which shows almost all the flux within 5 pixels. Spectra were extracted using different extraction heights, but the best S/N was obtained from an extraction slit height of 5, which was subsequently used for the analysis. The S/N of the final spectrum could possibly be improved by extracting with "optimal" weights.

Conversion of counts to flux was also carried out in the x1d task. Fluxes were corrected for the wavelength-dependent throughput of the 52x0.2" aperture, and for the light lost outside the extraction box, using the standard values in the APT and PCT reference files.

At the end of one-dimensional extraction, the spectrum consists of 59 separate pieces, which need to be summed together in a way that maximizes the signal-to-noise ratio of the final spectrum. We chose to weight the flux by the (S/N)^2 vs. pixel. Since the spectrum is mostly readnoise dominated, the weighting is thus proportional to square of the exposure time. This was done by introducing a separate keyword into the header, exp2. The the weighting in the 'splice' task was set to this 'header keyword' to apply the appropriate weight.

Abstract

We present the imaging observations made with the Space Telescope Imaging Spectrograph of the Hubble Deep Field -- South. The field was imaged in 4 bands, a clear CCD bandpass for 156 ksec, a long-pass filter for 22-25 ksec per pixel typical exposure, a Near-UV bandpass for 23 ksec and a Far-UV bandpass for 52 ksec. The clear visible image is the deepest observation ever made in the UV-optical-NIR wavelength region. The field contains QSO J2233-606, the target of the STIS spectroscopy, and extends 50 arcsec for the visible images, and 25 arcsec for the ultraviolet images. We present the images and catalogs of objects in the field.

1. Introduction

The images and catalogs presented here were taken with STIS as part of the HDF-S campaign between 1998 September 29 and October 10. For a description of the HDF-S, see Williams et al (1999), and on the web at http://www.stsci.edu/ftp/science/hdf/hdfsouth/hdfs.html. For more information about STIS, see Kimble et al (1998), Woodgate et al (1998), and Walborn & Baum (1998). This README file provides a preliminary description of the observations, the data reduction and the catalog. A more complete description will appear in Gardner et al (1999).

2. Observations

2.1. Description

The images presented here were taken in 4 different modes, FUVQTZ, NUVQTZ, F28X50LP, and 50CCD. The FUVQTZ and NUVQTZ used the MAMA detectors as imagers with the quartz filter. The MAMA field of view is a square, 25 arcseconds on a side, and was dithered so that the observations include data on a field approximately 30 arcseconds square. The 50CCD is filterless imaging with a CCD. The field of view is a square 50 arcseconds on a side, and the dithering extends to a square 60 arcseconds on a side. The F28X50LP is a long-pass filter which vignettes the field of view of the CCD to a rectangle 28 by 50 arcseconds. The observations were dithered to image the entire field of view of the 50CCD observations, although the exposure time "per pixel" is thus approximately half the total exposure time spent in this mode. The original pixel scale is 0.0244 arcsec/pixel for the MAMA images, and 0.05071 arcsec/pixel. All of the images have been drizzled onto a new scale of 0.025 arcsec/pixel. Table 1 describes the observations. The filterless 50ccd observations correspond roughly to V+I, and reach a depth of 29.4 AB magnitudes at 10 sigma in a 0.2 square arcsecond aperture (320 drizzled pixels). This is the deepest exposure ever made in the UV-optical-NIR wavelength region.

Table 1 -- description of the observations

Mode	Cent Wave	FWHM(A)	Det. FOV	Tot FOV	Tot Exp	Exp./pix	Depth
FUVQTZ	1370A	320A	25"x25"	30"	52124 sec	same	27.8
NUVQTZ	2220A	1200A	25"x25"	30"	22616 sec	same	27.5
F28X50LP	7230A	2720A	28"x52"	60"	49768 sec	22494	27.4
50CCD	5850A	4410A	52"x52"	60"	155590 sec	same	29.4

Notes to Table 1: See Walborn & Baum for filter tracings. The detector fields of view has been clipped slightly to remove vignetting. The total fields are approximate. Depths are AB magnitudes at 10 sigma in a 0.2 square arcsecond aperture.

The QSO is at RA=22 33 37.5883, Dec=-60 33 29.128 (J2000). The errors on this position are estimated to be less than 40 milli-arcseconds (Zacharias et al 1999). The position of the QSO on the 50CCD and F28X50LP images is x=1206.61, y=1206.32, and on the MAMA images is x=806.61, y=806.32.

2.2. Test data

Test observations of the field were made on 1997 October 29 through 31. These data are not used in the present analysis.

2.3. Observing plan

The observations were made under the following proposal ID numbers:

```
7633  Test Data           1997-Oct-29 through 1997-Oct-31
8071  PSF observations    1998-Sep-20 and     1998-Oct-19
8071  Flanking Fields     1998-Sep-27 through 1998-Oct-29
8058  Visits 5-15         1998-Sep-28 through 1998-Sep-30
8073  Visits 17-23        1998-Oct-01 through 1998-Oct-02
8074  Visits 24-30        1998-Oct-02 through 1998-Oct-04
8075  Visits 32-39        1998-Oct-04 through 1998-Oct-06
8076  Visits 40-50        1998-Oct-06 through 1998-Oct-09
```

The detailed phase 2 proposal, formatted listing of the observations, and archive information can be obtained from http://presto.stsci.edu/public/propinfo.html. The raw and pipeline processed data are non-proprietary, and are available through the STScI archive.

2.4. Dithering and Rotation

The images were dithered in RA and Dec in order to sample the sky at the sub-pixel level. In addition, variations in rotation of about +/- 1 degree were used to provide additional dithering for the WFPC2 and NICMOS fields during the STIS spectroscopic observations. The STIS imaging observations were interspersed with the STIS spectroscopic observations, therefore all of the images were dithered in rotation as well as RA and Dec. Imaging with the CCD was only done in the dark part of the orbits, while the bright part was typically spent doing G430M spectroscopy. The STIS MAMAs were only used in orbits which did not cross the South Atlantic Anomaly at any point in the orbit.

2.5. CR-SPLIT and pointing strategy

The CCD exposures were split into 2 or 3 "CR-SPLITS" which each have the same RA, Dec and rotation. This facilitates cosmic ray removal, although as discussed below, this was only used in the first iteration of the data reduction. The final 50ccd image is the combination of 193 readouts making up 67 "CR-SPLIT" pointings. The final F28X50LP image is the combination of 66 readouts making up 23 "CR-SPLIT" pointings. The F28X50LP image included 12 pointings at the northern part of the field, 1 pointing at the middle of the field, and 10 pointings at the southern half of the field.

2.6. PSF observations

In order to allow for PSF subtraction of the QSO present in the center of the STIS 50CCD image, two SAO stars of about 10mag were observed in the filterless 50ccd mode before and after the main HDF-S campaign. The stars are SAO 255267, a G2 star, and SAO 255271, a F8 star, respectively. These targets have spectral energy distributions in the STIS CCD sensitivity range similar to that of the QSO. For each star, 32 different CR-SPLIT exposures were taken (PID 8071, visits 1 and 13 respectively). The following strategy was used: (i) four different exposure times between 0.1 s and 5 s for each CR-SPLIT frame, to ensure high signal-to-noise in the wings while not saturating the center; (ii) a four-position dither pattern with quarter-pixel sampling and CR-SPLIT at each pointing with each exposure time; (iii) use of gain=4, to insure no saturation in the A-to-D conversion. During the observations for SAO255267, a failure in the guide star acquisition procedure caused the loss of its long-exposure (5s) images. Gain=4 has a well-documented large scale pattern noise that has to be removed, e.g., by Fourier filtering, before a reliable PSF can be produced. We have not reduced these observations. The raw and pipeline-processed data are available through the archive.

2.7. Flanking Field observations

The flanking field observing program (Lucas et al 1999) was designed to use WFPC2 to image a contiguous region containing the main deep fields of all three instruments. STIS was used in parallel to these observations to obtain 5100sec images in 50CCD mode. In general, there is very little overlap between the STIS flanking field observations and other HDF-S data. The exposures were made up of 4 dither positions, each CR-SPLIT into 2, for a total of 8 readouts. These images were reduced in a manner similar to that of the main field. We have not checked the astrometry on the STIS flanking field data. Therefore, the world coordinate system in the headers is only accurate to the astrometry of the Guide Star Catalog, i.e. of order 0.5-1.0 arcsec. We have not yet cataloged the flanking field observations. Astrometry and catalogs will be made available through this site when they are available.

There were an additional 9 orbits of data in 50CCD mode taken with the STIS centered on the NICMOS deep field. These data are presented with the NICMOS observations (Fruchter et al 1999).

Optical Imaging: Description of data products

Follow this link for a legend of the file names for the final reprocessed data.

Optical Imaging: Data Reduction

1. Bias, Darks, Flats and Masks

Standard processing of CCD images involves bias and dark subtraction, flatfielding, and masking of detector defects. The bias calibration file used for the HDF-S was constructed from 285 individual exposures, combined together with cosmic-ray and hot-pixel trail rejection.

The dark file was constructed from a "superdark" frame and a "delta" dark frame. The superdark is the cosmic-ray rejected combination of over 100 individual 1200 second dark exposures taken over the several months preceeding the HDF-S campaign. The delta dark adds into this high S/N dark frame the pixels that are more than 5-sigma from the mean in the superdark-subtracted combination of 14 dark exposures taken during the HDF-S campaign. Calibration of the images with this dark frame removes most of the hot pixels but still leaves several hundred in each image.

An image mask was constructed to remove the remaining hot pixels and detector features. The individual cosmic-ray rejected HDF-S 50CCD exposures were averaged together without registration. The remaining hot pixels were identified with the iraf "cosmicrays" task. These pixels were included in a mask that was used to reject pixels during the "drizzling" phase. Pixels that were more than 5-sigma below the mean sky background were also masked. The unilluminated portions of the detector around the edges were also masked out. The 30 worst hot pixel trails were also masked. These are features that run along columns caused by high dark current in a single pixel along the column.

Flatfielding was carried out by the STSDAS calstis pipeline using two reference files. The first, the "PFLAT" corrects for small-scale pixel-to-pixel sensitivity variations. This file was created from ground-test data but comparisons to a preliminary version of the on-orbit flat revealed only a few places where the difference was more than 1%. The PFLAT corrects for small-scale variations, but is smooth on large scales. The CCD also shows a 5-10% decrease in sensitivity near the edges due to vignetting. This illumination pattern was corrected by a low-order fit to a sky flat constructed from the flanking field observations.

2. Shifts and rotations

After pipeline processing, the CCD images were reduced using the IRAF/STSDAS package "dither", and test versions called "xdither", and "xditherII". These packages include the "drizzle" software (Fruchter & Hook 1998; Fruchter et al 1998; Fruchter 1998). We used "drizzle" version 1.2, dated 1998 February. The beta versions differ from the previously released version primarily in their ability to remove cosmic rays from each individual readout, and include tasks which have not yet been released.

The rotations used in combining the data were determined from the ROLL_AVG parameter in the jitter files, using the program, "bearing". We did not seek to improve on these rotations via cross-correlation or any other method. However, since we did use cross-correlation to determine the X and Y shifts, small errors in rotation would be removed in this iterative process, to first order.

Determination of the X and Y shifts was done with an iterative procedure. The first iteration was obtained by determining the centroid of the bright point source just east of the QSO, using the pipeline cosmic-ray rejected "crj" files. We could not use cross-correlation in this first iteration, since the very bright star on the southern edge of the field was present on images taken at some, but not all, dither positions, which corrupted the cross-correlation. The source we used for centroiding was clearly visible on all of the 50CCD and F28X50LP frames.

Using these shifts (which were accurate to better than 1 pixel), we drizzled the "crj" files onto individual outputs, which we combined using a median in the task "imcombine". This output image was placed back in the frame (x, y, rotation) of each individual read-out using the xdither task, "blot". After cosmic ray rejection, the blotted image was cross-correlated with the original data, corrected according to the cosmic ray mask, to determine the X & Y shifts used in the final combination.

3. Cosmic ray rejection

Each readout, ("flt" file science extension), was compared to the blotted image, and a cosmic-ray mask was created from all of the pixels which differed (positively or negatively) by more than a given threshold from the blotted image. In the version 1.0 released 50CCD image, this threshold was set to be 5.0 sigma. However, we believe that a small error in the sky level determination, introduced by the amplifier ringing correction discussed below, meant that this level corresponded to a "real" rejection at approximately the 3.0 sigma level. The cosmic ray masks were multiplied by the hot pixel masks discussed above, and resulted in about 8% of the pixels being masked as either cosmic rays or hot pixels. This is, perhaps, overly conservative. A less conservative cut (correcting the error in the sky value) would result in slightly higher exposure time per pixel, and thus an improvement of 1-2% in the signal to noise ratio.

This problem with the sky value was corrected in the F28X50LP image, and a 3.0 sigma level was used in the cosmic ray rejection.

4. Amplifier ringing correction

Horizontal features due to amplifier ringing, varying in pattern from image to image, were present in most of the STIS CCD frames. These were caused by the fact that when a pixel saw a very high signal, the bias level was depressed in the readout for the next few rows. The very high signals causing this ringing came from hot pixels and from the saturated QSO. We removed them with an iterative procedure that subtracted on a row-by-row basis, from each individual image, the weighted average of the background as derived from the innermost 800 columns after masking and rejecting "contaminated" pixels. The masks included all visible sources, hot pixels and cosmic-ray hits. For each readout the mask for the sources was obtained from the "master blot image" derived by combining together all images available in the filter, blotted to the position of the considered frame. A "minmax" rejection criterion was applied to the remaining pixels, which excluded the highest and lowest 6% of the unmasked pixels from the average. The IRAF script implementing this procedure, developed for the HDFS, will be made available to the community.

Heavily smoothing the images reveals very slight horizontal residuals which were not removed by the current choice of smoothing/rejection parameters.

5. Drizzling it all together

The final image combination was done by drizzling the amplifier-ringing corrected pipeline products together onto a single output image. The exposures were weighted by the square of the exposure time, divided by the variance, which is (sky+rn^2+dark). The rotations were corrected so that North is in the +y direction, and the scale used was 0.492999 original CCD pixels per output pixel so that the final pixel scale is exactly 0.025 arcsec/pixel. For the 50CCD data we used a pixfrac=0.1, which is approximately equivalent to interleaving, where each input pixel falls on a single output pixel. For the F28X50LP data we used pixfrac=0.6, as a smaller pixfrac left visible holes in the final image. See Fruchter & Hook (1998) for a discussion of the meaning of the drizzle parameters. The final image is given in counts per second, which can be converted to STMAG using the PHOTFLAM parameter supplied in the header. We also supply the weight image, which is the sum of the weights falling on each pixel. For the F28X50LP image, we supply an exposure-time image, which is the total exposure time contributing to each pixel. We have multiplied this image by the area of the output pixels. The world coordinate system in the headers was corrected so that North is exactly in the +y direction, and the pixel scale is exactly 0.025 arcsec/pixel. However, we have provided the original header information in a separate file.

6. Window reflection

A window in the STIS CCD reflects light from bright objects slightly out-of-focus to the +x, -Y direction (SE on the HDF-S images). The window reflection of the QSO (which is saturated in every 50CCD and F28X50LP exposure) is clearly visible in the F28X50LP image, but has been partially removed from the 50CCD image by the cosmic-ray rejection procedure. We wish to emphasize that it has only been partially removed -- there remain residuals. These residuals should not be mistaken for galaxies near the QSO, nor should they be mistaken for the host galaxy of the QSO. There is additional reflected light from the QSO (and from the bright star at the southern edge) evident in the images. It is the belief of the authors of this document that the version 1.0 released images are not appropriate for searching for objects very close to or underlying the QSO, and that such a search would require re-processing the raw data with particular attention paid to the window reflection, other reflected light, and to the PSF of the QSO. The diffraction spikes of the QSO are smeared in the final images by the rotation of the individual readouts. The QSO is not saturated in the MAMA images.

UV Imaging: Description of data products

Follow this link for a legend of the file names for the final reprocessed data.

UV Imaging: Data Reduction

The near-UV and far-UV images are respectively the weighted averages of 12 and 25 registered frames, with total exposure times of 22616 and 52124 sec. Prior to combination, all frames were processed with CALSTIS, including updated high-resolution pixel-to-pixel flat field files for both UV detectors. Geometric correction and rescaling were applied in the final combinations via the DRIZZLE package. Dark subtraction for the near-UV was done by subtracting a scaled and flat-fielded dark image from each near-UV frame, with scaling determined from the occulted right-hand corners of the detector. For the far-UV images, CALSTIS removes a nearly flat dark frame, but the upper left-hand quadrant of STIS far-UV frames contains a residual ``glow'' in the dark current after nominal calibration. This glow varies from frame to frame and also appears to change shape slightly with time. To remove the residual dark current, the 16 far-UV frames with the highest count rates in the glow region were co-added without object registration but with individual object masks for the only two obvious objects in the far-UV frames (the quasar and bright spiral NNE of the quasar); the result was fit with a cubic spline to produce a glow profile. This profile was then scaled to the residual glow in each frame and subtracted prior to the final drizzle. Note that even during observations with a strong dark glow, the dark is an order of magnitude higher than normal but still quite low, reaching rates as high $6x10^{-5}$ counts sec^{-1} pix^{-1}. The glow thus appears as a higher concentration of ones in a sea of zeros, and the subtraction of a smooth glow profile from such quantized data over-subtracts from the zeros and under-subtracts from the ones. These effects are visible to the eye in the corrected data, even when smoothed out considerably in the final drizzled far-UV image. A low-resolution flat-field correction was applied to the far-UV frames after subtraction of the residual dark glow; the near-UV frames require no low-resolution flat field correction.

Currently, geometrically corrected NUVMAMA/F25QTZ and FUVMAMA/F25QTZ frames do not have the same plate scale; thus, before registration, all near-UV and far-UV frames were geometrically corrected, rescaled to 0.025" pix^{-1}, and rotated to align North with the +y image axis. The roll angle specified in the jitter files was used to determine the relative roll between frames, and the mean difference between the planned roll and the jitter roll determined the absolute rotation. All near-UV and far-UV frames were then cross-correlated against one of the far-UV frames (o52f44uwq) to provide shifts in the output coordinate system. Note that centroiding on the quasar in all far-UV and near-UV frames yields the same shifts as cross-correlation, within 0.1 pixel. The calibrated frames were then drizzled, including the above corrections, rescaling, rotations and shifts, to a 1600x1600 pixel image. The world coordinate system in the image headers has been updated to exactly reflect the plate scale and alignment, and also the NRL position of the quasar.

For both the far-UV and near-UV frames, individual pixels in each frame are weighted by the ratio of the exposure time squared to the dark count variance; this weights the exposures by $(S/N)^2$ for sources that are fainter than the background. Although the far-UV dark profile is smooth, the near-UV dark profile is an actual sum of dark frames, and so we smoothed the near-UV dark profile when determining the drizzle weights. With this weighting algorithm, pixels in the upper left-hand quadrant of a given far-UV image contribute less when the dark glow is high, and contribute more when it is low. The statistical errors (counts sec^{-1}) in the final drizzled image, for objects below the background (e.g., not the quasar), is given by the final drizzled weights file raised to the -1/2 power.

The drizzle "dropsize" (a.k.a. pixfrac) was 0.6, thus improving the resolution over a dropsize of 1.0 (which would be equivalent to simple shift-and-add). The 1600x1600 pixel format is the smallest ``standard'' image size that can contain all dither positions; pixels outside of the dither pattern are at a count rate of zero. The pixel mask for each near-UV input frame included the occulted corners of the detector, a small number of hot pixels, and pixels with relatively low response (those with values <=0.75 in the high-resolution flat field). The pixel mask for each far-UV frame included hot pixels and all pixels flagged in the data quality file for that frame. When every input pixel drizzled onto a given output pixel has been masked, that pixel has been set to zero.

WFPC2 Data Reduction / Technical Issues

Check the page with warnings and advisories before making any use of the data.

Information is available about the following topics:

WFPC2 imaging

Description of data products

1. General

Follow this link for a legend of the file names for the final reprocessed data.

The version 1 images represent our best shot at a first combination of the WFPC2 data taken in the main portion of the Hubble Deep Field South. Images were taken in the same four filters as for the original Hubble Deep Field: F300W, F450W, F606W, and F814W. For each filter, we have produced a combined data image, named fxxx_comb.fits (xxx stands for 300, 450, 606 or 814), and a weight image, named fxxx_weight.fits. Note that both data and weight images are presented in a single mosaic, with all four WFPC2 detectors combined onto the same image plane.

2. Combined Image

The combined image is the result of combining all individual exposures, optimally weighted for the background signal, and resampled to a pixel scale of 0.0398" using the "Drizzle" package (Fruchter & Hook 1998). The images are expressed in counts per second at a gain of 7. They have been rotated to have North approximately up (about 0.5 degrees from vertical). The coordinates of the images are set in the header WCS parameters, and can be retrieved for example via the IRAF task xy2rd. The absolute astrometry of the field has been derived from a match with four astrometrically measured stars kindly provided by the Naval Observatory, and is likely to be accurate to about 40 mas.

The depth and coverage for each filter varies across the field of view, due to the variety of pointings that were combined together. The image depth wanes when approaching the edges of the area covered, as well as in a near-vertical seam between detectors which received much lower coverage than the central region of each chip. This variable depth is reflected in the image weights, described below.

As a consequence of the decreased image quality, the outer regions of each image are less reliable, especially in terms of cosmic ray rejection. Any oddly-shaped objects appearing in only one filter near the edge of the images presented here has a good probability of being a piece of an unrejected cosmic ray.

Images have been trimmed where the (median) weight per pixel is less than a filter-dependent cutoff value: 7.e7 for F300W, 5.e7 for F450W, 1.e7 for F606W, and 2.e7 for F814W. Images also take the value of 0 where no valid pixels are available, such as at the center of the brightest stars - which saturate in all F606W and F814W images.

3. Exposure time and weight

The total effective exposure time for these images is:

```
F300W   140,185 s
F450W   100,950 s
F606W    81,275 s
F814W   100,300 s
```

Several images need special treatment and have been rejected in this combination; their inclusion in a future version is likely to improve the noise by about 5 to 10%.

The weight images we provide represent the expected (theoretical) inverse variance due to the background sky in each image. However, due to the correlated nature of noise in resampled images, the variance measured on a single-pixel scale will in general differ from the inverse of the weight. The weight image can be used to estimate the expected noise on large scales, where the noise correlation abates. Specifically, the variance of the *total* signal in an area including N pixels scales with sqrt(N / < W >) for N sufficiently large (> 100 or so), where W is the weight reported for each pixel.

4. Photometry

WFPC2 detectors differ slightly in their sensitivity. The individual input images have been scaled to the response of the WF3 detector, thus the zero points determined for WF3 (at gain 7) apply. For reference, the most recent determination of the zero point for infinite aperture in the VEGAMAG system is:

```
F300W     19.43
F450W     22.02
F606W     22.90
F814W     21.66
```

Data reduction

A short description of the steps taken to produce the WFPC2 Version 1 images.

1. Preparation

The WFPC2 group produced a new superbias, superdark, and flat field for each of the filters. The superdark showed a general increase in dark current with respect to the previous version, and a larger number (about 4000 per detector) of permanent hot pixels. Although permanent hot pixels seem to subtract reasonably well, all pixels with dark current greater than 0.02 DN/s (0.14 e/s) were flagged as bad and not used in further combinations.

In addition, daily hot pixel masks were produced to track the newly produced hot pixels. Daily masks were produced by median combination of all F300W images taken in a given day. The median combination excludes objects, which fall on different places in the chip due to the dither and roll changes in the telescope, and brings up hot pixels, which are then flagged. This procedure failed for October 4, 9 and 10, when not enough F300W images were taken; we used the October 5 mask for October 4, and the October 8 mask for October 9 and 10. These masks were used in step 2 and in generating the individual weight files for step 5.

2. Quality verification and pipeline

First, each image was indidually inspected by eye, and any problems - moving objects, charge trails, cosmic ray showers, bias jumps, the characteristic cross due to Earth-scattered light - noted in the master log file. For charge trails, the affected areas were masked out by editging the image quality file. Moving objects and cosmic ray showers generally are rejected automatically in further processing, but the quality of the rejection was checked explicitly later on.

Individual images were processed by the standard CALWP2 pipeline, using the new superbias, superdark and flat field.

Finally, each image had the sky subtracted and the value recorded in the header.

3. Image registration and first combination

A preliminary image registration was obtained with two independent methods. The first was to adopt the position recorded in the jitter file, derived from the average measured position of the guide stars throughout the observation. The second was to cross-correlate the image with an image pair chosen as reference. [The second method could not be used for F300W because of the low signal levels.] Images for which the two methods yielded comparable results were used in the first combination, while images for which they disagreed were excluded from the first combination and included again after their position was redetermined in step 3.

The first combination was done as follows:

- For each input image, use DRIZZLE to produce a mosaic of the four chips (this mosaic will have a small inter-chip gap); each image is shifted and rotated to a common reference position, which has North approximately up.
- Median-combine all images with "good" shifts for each filter, excluding pixels masked in the hot pixel list (step 0) and pixels too close to the pyramid edge; this produced a first reference image (the "median" image) for each filter.

4. Refinement of the pointing measurement

The median image was then used to refine the position measurement for each of the input images. For F450W, F606W and F814W, this was done by cross-correlating each individual mosaic with the median image. In a few cases the quality of the cross-correlation indicated a possible rotation; these cases were excluded from the Version 1 combination.

Again, F300W required a different procedure, since the low signal level causes the full-image cross-correlation to be dominated by cosmic rays. Instead, we cut out two 100-pixel regions around the two brighest stars, and cross-correlated those against the reference image. The shifts were generally in good agreement and their average was adopted; in a few cases, one of the stars was affected by a cosmic ray and the other was used. For one image, both stars were affected by a cosmic ray and unusable; that image, 2704, was excluded from the final combination.

The typical uncertainties in the alignment of individual images are between 5 and 10 mas for F450W, F606W, and F814W, and between 10 and 20 mas for F300W.

5. Cosmic rays and weight image

The identification of cosmic rays, a difficult problem in the absence of cosmic-ray splits, was done by comparing each image to an "expected" image based from the median image. The expected image was produced by BLOT using the updated positions, and the combination of DERIV and DRIZ_CR was used to identify cosmic rays. This process was in general very successful except close to the edges of the median image, where there was not enough information to identify cosmic rays properly. Pixels affected by cosmic rays were identified in the cosmic ray mask.

6. Inter-chip alignment verification

The relative positions of the four detectors in the sky were verified using the following procedure:

- For each filter, a separate image was produced for each of the detectors; these images overlap (by about 10" in the N-S direction, and about 3" in the E-W direction) due to the variety of pointings used
- The positions of objects in the overlap area were compared to determine shift corrections (WF4 was used as reference)

- For the PC, we used the average of the shift determined by comparison with WF2 and WF4.
- In addition, we also determined the (very small) inter-filter shift due to both the so-called filter wedge and the difference in the position of the reference image
- After these updates, we estimate the relative alignment of the images in different filters to be good to better than 5 mas, and between detectors to about 15 mas.

7. Problem cases

Images affected by a bias jump or by the cross pattern due to scattered Earth light were corrected by applying a median filter (width 21 pixels) to the image obtained after subtracting the "expected" image produced by BLOT in step 3. The median filter preserves the edges and produces an adequate subtraction for a sharply varying background, such as that produced by either a bias jump or the scattered Earth light. Direct inspection confirmed the subtraction to be satisfactory.

Cosmic rays were identified properly in the vast majority of cases. A handful of exceptions - usually due to a very large cosmic ray - were identified at this stage and excluded from further processing; such images will be recovered as part of the Version 2 combination.

Similarly, moving targets usually were flagged properly, but in some cases left visible residuals; these were excluded from further Version 1 processing.

Altogether, approximately 7% of the data were excluded from the final combination because of uncertain pointing or uncorrected blemishes; these are identified in the master log file.

8. Final combination

First, the (small) difference in sensitivity between the detectors was corrected by scaling to a common zero point; WF3 was chosen as reference.

Second, the pixel weights of each input file were determined as the inverse variance of the background within each pixel, scaled to the output pixel size.

DRIZZLE was then run on all acceptable images for each filter with the following parameters:

- SCALE = 0.400, PIXFRAC = 0.500 for the Wide Field Cameras
- SCALE = 0.875, PIXFRAC = 0.600 for the Planetary Camera

resulting in a final pixel size of 0.0398" (verified by coalignment with astrometric stars, see below).

The size of the output image is 4096 x 4600 pixels, or 163" x 183" - enough to include all the area with valid data. The final image was set to 0 for low-weight pixels, which suffer from uncorrected cosmic rays and other blemishes and have low scientific value.

As a final step, the image was astrometrically calibrated by using four stars with absolute astrometry determined by the Naval Observatory in the Hipparcos reference frame. The WCS parameters in the header were updated to reflect the best astrometric solution, with an expected error of 40 mas dominated by systematics in the astrometric position of the reference stars.

Appendices

A. The weight images forDRIZZLE

The DRIZZLE program allows each input image to be assigned a pixel-by-pixel weight. We used the inverse variance of the background in each input pixel, scaled by the fourth power of the scale ratio; this produces final weigths that are representative of the inverse variance per pixel on large areas. (The variance measured on small areas is smaller because of the pixel-to-pixel correlation.)

Specifically, we defined the weight image as follows:

```
VARIANCE = [(DARK+BACKGROUND)*FLATFIELD/GAIN + READNOISE^2] /
   (FLATFIELD^2 * EXPTIME^2)

WEIGHT = 1 / (SCALE^4 * VARIANCE)
```

where the dark current DARK and background BACKGROUND were estimated from the image average, rather than on a pixel-by-pixel basis. DARK, BACKGROUND and READNOISE are in DN/pixel; the GAIN and READNOISE were taken from the WFPC2 Instrument Handbook, and are different for each chip; and the FLATFIELD is the inverse of the value in the flat field reference file, which is the INVERSE flat field.

The SCALE parameter is the ratio of output to input pixel size. Since the output size is 0.4 WF pixels, SCALE = 0.400 for WF2, WF3 and Wf4, and SCALE = 0.875 for the PC.

The WEIGHT was set to zero if any of the following conditions applies:

```
dark current > 0.02 DN/s       (hot pixel)
flagged as cosmic ray
inverse flat field > 1.7       (too close to the pyramid edge, vignetted)
x, y < 60 (PC) or < 40 (WF)    (too close to the pyramid edge)
x, y > 795                     (too close to the outer edge)
```

B. Photometric Information

Filter	F300W	F450W	F606W	F814W
Multiplicative factor:				
PC	1.025	1.027	1.008	1.019
WF2	0.984	1.008	0.979	0.994
WF3	1.000	1.000	1.000	1.000
WF4	1.019	1.030	1.015	1.017
Final zero point				
Vegamag	19.43	22.01	22.90	21.66
ABMAG	20.77	21.93	23.02	22.09
STMAG	19.45	21.53	23.21	22.91
Photflam	5.985e-17	8.797e-18	1.888e-18	2.449e-18

These zero points differ very slightly from those used for the original HDF (-0.02 in F300W, -0.01 in F606W). The camera throughput has remained constant through the years, and the slight differences are due to new measurements of the zero points over the last three years.

C. New Superbias reference file

Name I9817383U.R2H

Created by: Shireen Gonzaga, August 25, 1998

The reference bias file ("superbias") was produced from an average of 120 on-orbit bias frames taken between December 4, 1997 and August 13, 1998 (listed in the file header).

The raw images were retrieved from the archive and recalibrated (mask, atod, and bias level corrections) using CALWP2 Version 1.3.5.2, which removes separate bias levels for the even and odd data columns based on values in columns 9-14 of the extracted engineering datafile (x0h).

The STSDAS wfpc "mkdark" task (identical to a version of "crrej" previously used to make reference bias files) was used to combine the calibrated frames and remove cosmic rays. The task was run with four iterations, using sigmas set to 6,5,5,and 4; Pixels are rejected if they are N sigma above or below the initial guess image. The first initial guess image was taken to be the median of the stack; subsequent iterations use the computed average image as the initial guess. In addition, pixels within 1 pixel of a rejected pixel (in a '+' pattern) were discarded if they deviated by more than 2,2,1.5, and 1 sigmas, respectively for each iteration. Pixels using less than 100 input images were marked in the DQF.

D. New Superdark reference file

Name I9T1701QU.R3H

Created by: Michael S. Wiggs and Stefano Casertano, September 25, 1998.

The reference dark file ("superdark") was created from an average of 120 input darks. The input darks were from the date range of 11/05/1998 thru 21/08/1998, and are named in the image header. All datasets were calibrated using CALWP2.1.3.5.2, utilizing the most up-to-date reference files, including the new superbias: i9817383u. The datasets were then run thru the STSDAS task CRREJECT in 8 groups of 15. This was done assuming a total readout, a-to-d conversion, etc. noise of 6 electrons. The cosmic rays were removed iteratively, with 4 sigma rejection, and then additional iterations were made with 3 sigma and 2 sigma rejection levels.

The resulting 8 "crrejected" datasets were averaged together to create the final 120 image superdark. The superdark image was then normalized to a darktime of 1.0 second for each CCD.

The associated DQF file was computed in the following manner:

- If more than 60 input files are valid and the dark current is <= 0.02 DN/s, then the pixel value is 0 (valid data).
- If more than 60 input files are valid and the dark current is > 0.02 DN/s, then the pixel value is 512 (uncorrectable warm pixel).
- If >= 60 input files are valid, set the pixel value to the bitwise OR of all input masks (any flag set in any of the input file is set on the mask).

E. New Inverse Flat Field reference file

```
F300W: I9T1701IU.R4H
F450W: I9T1701KU.R4H
F606W: I9T1701MU.R4H
F814W: I9T1701OU.R4H
```

Created by: John Biretta and Michael S. Wiggs, September 28, 1998.

The flat fields will be described in a forthcoming document.

NICMOS Data Reduction / Technical Issues

Check the page with warnings and advisories before making any use of the data.

Information is available about the following topics:

NICMOS imaging

Description of data products

1. General

The final reprocessed data (version 1.0) can be retrieved from the directory **nicmos/** on this anonymous ftp site. This directory represents our best present combination of the NICMOS images and the STIS images of the NICMOS field as of 23-NOV-1998.

The field was observed with the F110W, F160W and F222M filters of NICMOS Camera 3 (pixel size = 0."2) and in 50CCD (open filter) mode with STIS. The images were processed using a variant of the CALNIC and DIMSUM procedures to remove the electronic pedestal, dark and sky, were registered using new versions of tasks in the STSDAS "dither" and ditherII STSDAS packages (Fruchter, Hook, Busko and Mutchler 1997, Fruchter and Hook 1998), and combined using Drizzle (Fruchter & Hook 1998). Some images which had noise levels substantially larger than predicted (nearly always as a result of persistent cosmic rays in images taken shortly after an SAA passage) were excluded from the combination. The total exposure times in seconds are:

```
F110W   108539
F160W   128441
F222M   103163
50CCD    25900
```

The F222M images were taken during "bright" time, i.e. when the telescope was pointed near the bright limb of the earth. The F110W and F160W were taken in dark time. The 50CCD images, unlike the NICMOS images, were taken outside of CVZ, and thus the telescope was pointed away from the earth limb.

The images have all been combined with North up (the orientation, based on the HST guide stars, has an estimated error of ~0.1 degree) and astrometric zeropoint was set using the position of a star visible in the NICMOS image whose position was determined by the Naval Observatory (with an estimated total error of ~50 mas).

Follow this link for a legend of the file names for the final reprocessed data. In short, the available images are:

```

In the subdirectory pf1p0/, another version of the F110W, F160W and F222M images can be found. These images were created with a "pixfrac = 1.0" and are primarily of use to those wishing to study sources at the very edges of the images, where the above images begin to "break-up" due to a lack of sufficient input images to cover the output plane at the finer pixfrac scale.

The subdirectory individual/ contains all individual calibrated (un-combined, un-mosaiced) NICMOS exposures as gzipped tar files.

2. Understanding the images

The NICMOS images in this directory were created using the Drizzle parameter values, pixfrac = 0.45, scale = 0.36974. The scale was set to create an output pixel size of 0."075, or exactly three times the scale of the STIS images of 0."025 of both the NICMOS field and the primary quasar field. The pixfrac is a compromise between providing uniform coverage as much of the field as possible and obtaining the highest possible resolution. These goals were, however, fairly well met, as nearly all of the available field has a ratio of r.m.s. to median of the weight image of less than 0.3, and the FWHM of the stars in the J and H band images are about the width of an input (0."2) NIC-3 pixel.

The noise in the images is estimated by the weight map images. The weight maps of individual input images were set equal to the square of the exposure time of the image divided by the expected r.m.s. in counts of the image. This is the inverse of the expected variance of the image. Drizzle divides the input weight up among the output pixels so that the total sum of the pixels in the input image is preserved.

If one measures the r.m.s. in the sky of the drizzled image one will find it does not equal the square root of the inverse of the weight map. There are two factors that must be applied to make these numbers equal:

1) The inverse variance map estimates the noise in a single INPUT pixel, but drizzle divides the flux among scale**2 output pixels. One must therefore divide the estimated r.m.s. by scale**2 (or multiply the weight map by scale**4). This has already been done for the WFPC2 images (as part of creating the PC+WFPC mosaic), but was not done for the STIS or NICMOS images.

2) Drizzling causes adjacent pixels to be correlated. The pixel-to-pixel noise therefore underestimates the true noise of a larger area. This correlation factor is a function of the ratio of (pixfrac/scale). For the NICMOS images this factor is ~1.9, for the STIS image it is ~1.8.

In the case of the NICMOS images then the noise directly estimated from the weight map is about a factor of 14 = 1.9/(0.36*0.36) larger than that measured on small-scales from the images.

In order to obtain the highest signal-to-noise from photometry on a drizzled image one should perform a weighted sum of pixels in the region of interest. The program, weighted block average or wba, found in

http://archive.stsci.edu/pub/hdf/v2/drizzled/

will perform a weighted AVERAGE (note not sum) of a rectangular region of a drizzled image and its weight image. Notes on using the program can also be found on this page.

3. PSF Convolution of the STIS Image

In order to allow a more accurate photometric comparison of the STIS and NICMOS images, the STIS image was convolved to the resolution of the NICMOS image and the 0."025 pixels of the STIS image were block-summed to the 0."075 resolution of the NIMCOS image.

The convolution kernel was created using Tiny Tim and the IRAF task "psfmatch". First a NICMOS F160W PSF was created on the STIS 0."025 drizzled STIS pixel scale. This PSF was then divided in fourier space by a gaussian comparable to the core of the STIS PSF. This step was accomplished using psfmatch. The resulting kernel was then rotated to the average orientation of the NICMOS image, and was applied to the STIS image using the STSDAS task fconvolve. The resulting convolved image was then block-summed 3x3 to the NICMOS pixel scale.

Data Reduction

1. Introduction

The NICMOS HDF-South images were processed using a combination of STScI pipeline procedures and customized tasks designed to remove the basic instrumental signatures from the data. Further processing to remove bad pixels and residual artifacts, and final image combination, were carried out using the Drizzle procedure (Fruchter & Hook 1998) and associated software. A detailed description of the methods used will be presented at a later date both on this web page and in various publications, but here we give a brief outline of the steps taken.

The observations were taken in MULTIACCUM mode using the SPARS64 sample sequence. In this operating mode, the array is first reset and then read out nondestructively at various regular time intervals to sample the accumulating signal throughout the integration. All exposures were obtained using NSAMP = 5, 10, 15, 20 or 25 readouts.

2. Basic Image Processing

1) The images were partially processed through the STSDAS 'calnica' pipeline applying the steps ZOFFCORR, ZSIGCORR, MASKCORR, BIASCORR, NOISCALC, DARKCORR, and NLINCORR. Standard STScI reference files from the calibration database were applied during these steps. This processing accomplishes the subtraction of the nominal bias and dark current from the readouts of the MULTIACCUM image. At this stage, then, no cosmic-ray correction, flat-fielding or conversion to counts per second have been performed. However, some components of NICMOS biases and darks are not temporally stable, and are thus not fully removed by the pipeline processing.

2) In particular, NICMOS data are subject to floating bias levels in each readout quadrant which can change during the course of a MULTIACCUM sequence (sometimes known as "pedestal"). These variable bias levels were dealt with in two stages using a routine we call NBIASFIX. Bias drifts during the course of each individual MULTIACCUM exposure were measured and removed with a customized procedure which also identifies and eliminates the occasional bias jumps or bands (which are particularly common in the last readout of a MULTIACCUM sequence, a.k.a. the "last read anomaly"). The effect of these processing steps is to remove changes in bias levels from readout to readout, leaving data which accumulate in a simple linear fashion with time. However a net (unknown) DC bias level is still present in the data (see step 4 below).

3) The data were then processed through the UNITCORR and CRIDCALC stages of 'calnica.' A slope is fit to the accumulating counts versus time in each pixel. CRIDCALC detects sharp discontinuities in the accumulating counts versus time ramp and identifies these as cosmic ray events. When these occur, the offending readout is eliminated for the pixel in question and the slope is recalculated without it, thus effectively removing the cosmic ray from the image. The output of this processing step is an image representing count rates for each pixel. Note that at this stage in our processing procedure the data have not yet been flatfielded.

4) Step 2 above removes drifts in bias during a readout sequence but not the absolute DC bias level. Sky and bias subtraction were accomplished using the data frames themselves through an iterative procedure. Simple median "sky+bias" images were created from the data taken in each filter grouped by NSAMP (i.e. number of readouts). These were then fit to each image allowing one multiplicative degree of freedom (the DC sky level) and four additive degrees of freedom (the bias levels in each quadrant). The sky and bias subtracted images were flat fielded, coaligned and assembled into mosaics for each bandpass. Objects were identified in the mosaics and masks were created marking their positions in each individual exposure. New sky+bias images were then created in a second iteration, using the scaling information determined in the first pass, and with objects masked during the combination. These second pass sky+bias frames were then scaled again to the individual images following the same procedure as before and subtracted to produce the new sky and bias subtracted exposures, which were then flatfielded. This iterative procedure effectively removes all the additive components (sky plus residual dark and bias) left over after the initial calnica pipeline processing.

5) Error models were created for each image using information about detector characteristics, sky levels, number of readouts and total integration time used for each pixel. The noise level in each image was compared to this model, and the frames were given careful visual inspection. In particular, signs cosmic ray persistence, "monster" cosmic rays, and moving targets (satellite trails, etc.) were noted. A significant number of frames were badly affected by cosmic ray persistence, which occurs in exposures taken after passages through the South Atlantic Anomaly. Frames which were irredeemably ruined by CR persistence were eliminated from the final data set. In general, measured image noise agreed well with the error models. Cases where there was a significant disagreement were tabulated and the relative variance scaling was used to re-weight the images in the final summation (section 12 below).

6) The F222M (K-band) data required special processing. The large background count rate in these data allowed us to identify previously unrecognized shortcomings in the nonlinearity corrections made by the standard pipeline. We constructed a new linearity correction procedure using in-flight calibration data and applied it to the F222M images which significantly improved the quality of the subsequent sky subtraction. Note that this new correction was not applied to the version 1 reductions of the F110W and F160W images; this may be done for a future version 2 release of the HDF-South NICMOS data; however, we expect such a corretion to only affect the brighter stars in these images. Raw F222M images showed a number of ring-like features which we attributed to out-of-focus thermal emission from dust particles lodged on one of the optical surfaces, probably the Field Offset Mirror (FOM). These were found to move several times during the course of the HDF-South observations, evidently at times corresponding to resets of the FOM position. The complete ten-day data stream in F222M was broken into four subsets corresponding to the four intervals where the dust features were found to be stable, and sky subtraction was carried out separately for each of these four intervals.

7) The final sky subtracted images were flatfielded using standard reference files from the calibration pipeline.

3. Image Combination

8) The images were spatially co-registered using cross correlation procedures allowing for rotations between images (necessary because the telescope roll angle changed from exposure to exposure as part of the dithering procedure designed to keep the HDF-S QSO in the STIS spectroscopic apertures); however, the rotation angle used was that provided by the spacecraft telemetry and was not determined independently.

9) Residual bad pixels (including the worst of the cosmic ray persistence features) were identified and masked via an iterative procedure described in the 'dither' and 'ditherII' package tutorial (Fruchter and Mutchler 1998). The resulting bad pixel masks for each image were combined with a custom static mask designed to exclude known and suspected bad pixels in the array, as well as the vignetted region at the bottom edge of the NIC3 field of view and a small unstable region at the upper right.

10) Pixels in the NICMOS detector arrays are not uniformly sensitive across their areas. Therefore undersampled images are subject to intrapixel response effects, wherein the measured counts depend sensitively on the positioning of the source within the pixel. This can have a particularly large effect on point sources observed with Camera 3, causing the measured counts in the peak pixel to vary considerably more than simple shot noise statistics would predict. We found that our procedure designed to identify residual bad pixels and cosmic rays was frequently "zapping" the peaks of bright stars for this reason. The peaks were therefore manually "unzapped" to correct for this effect. The final summed HDF-S NICMOS images should be largely free of photometric uncertainty due to these intrapixel response effects because they are averages over more than one hundred individual exposures with randomly placed sub-pixel centerings.

11) NICMOS images containing relatively bright sources are subject to electronic ghosting artifacts (known as the Mr. Staypuft effect. This phenomenon manifests itself in two ways. First, bright objects can produce "streaks" of elevated signal along image columns. These appear both in the columns where the object lies and also in the corresponding columns in other detector quadrants. Second, faint ghost images of a bright source in one detector quadrant also appear in the other three quadrants at the corresponding pixel positions. Both effects were visible in the HDF-S F110W and F160W images, arising from the small number of brighter stars present in the field. The column ghosts were quite prominent and were handled by fitting and subtracting medians from each column in each exposure. Pixels corresponding to the positions of all known astronomical sources were masked and excluded from the median fitting procedure to ensure that they would not bias the measurement. The fainter ghost images of the four brightest stars were invisible except in the final drizzled image combinations, where they appeared as faint, false "objects." These were eliminated by masking small areas in each exposure around their expected positions in each detector quadrant (i.e. positions 128 pixels away in each axis from the actual location of the responsible stars). These masked regions were set to zero in the weighting maps used to combine the data (see section 10 below). Thanks to the fact that the HDF-S dither pattern involved rotations, the regions which were masked and excluded at one telescope rotation were filled by "good" data from another, ensuring that the ghosts could be eliminated without producing gaps in the final images. However the effective exposure time underneath the regions affected by the Mr. Staypuft ghosts is significantly reduced from the total, and thus the resulting image noise is higher. The output pixel-wise weighting maps from the drizzling process, which are available together with the HDF-S images themselves, show distinctive "holes" which can be used to identify the locations where the ghost masks most severely affect the data.

12) The images were drizzled together using the individual bad pixel masks generated for each exposure combined with the overall static mask (see section 9 above), using spatially dependent weighting maps generated using the known flatfield pattern and noise characteristics of the data (see step 5 above). This procedure ensures optimal weighting by inverse variance during image combination. A new calibration for NICMOS Camera 3 geometric distortion (updating that in Cox et al. 1998) was used during drizzling. NICMOS pixels are slightly rectangular when projected onto the sky, an effect which is also removed during drizzling using the geometric distortion correction. The pixel scale for the final drizzles had a linear extent of 0.36974 original NIC3 pixels, a scale chosen to be exactly 3 times that of the final drizzling scale used for the STIS 50CCD images. The final drizzled pixel scale is therefore 0.075 arcseconds per pixel in the NICMOS images, and 0.025 arcseconds per pixel in the STIS-on-NICMOS image. The "drop size" or "pixfrac" for the NICMOS drizzles was set to 0.45 input pixels. The images in all bandpasses (including the STIS-on-NICMOS data) were drizzled so that they were co-aligned and so that North is up (i.e. in the positive y pixel direction) and East is right (i.e. negative x) to the best of our knowledge of the orientations of the science instrument apertures.

4. STIS image on the Main NICMOS Field

The STIS on NIC image includes 9 orbits of unfiltered STIS images of the NICMOS HDF-S field. Pairs of cosmic-ray split images were obtained at 9 dither positions during two visits. These frames were processed using the same procedures as for the main STIS field. Since the CCD was annealed between the first and second visits, an updated dark frame was created for the version 2 processing. The version 1 processing masked hot pixels from both darks in the post-annealing data. These masks were multiplied by an edge mask to create the final static masks.

The mode of the sky pixels was determined using an iterative rejection algorithm and subtracted from each cosmic-ray split frame. Image shifts were also determined individually via aniterative process of cosmic-ray masking and cross-correlation. The rotation angle was essentially identical for all these frames. The amplifier ringing correction described by Gardner et al. was applied, but the improvement to the sky was negligible for this field. The images were drizzled onto 0.025" pixels, scale = 0.492999, using a drop size of 0.6 pixels. The images were weighted by the variance of the sky, or wt_scl = t ** 2 / (N_sky + R^2 + N_dark). A small rotation of 5.55 degrees was included to rectify the image.

Photometric Zeroponts

There remains some significant uncertainty in the absolute photometric calibration of the NICMOS HDF-South images. The nominal photometric calibration information which is inserted into image headers by the STScI CALNICA data reduction pipeline use the most up-to-date calibration reference files taken from the STScI Data Archive. However, recent information based on revised ground-based photometry of the fundamental NICMOS photometric standards by Persson et al. 1998 (AJ 116, 2475) suggests that calibrations based on these reference files may be incorrect by 5 to 14% for some filters. Moreover some zeropoints also disagree with those used by the NICMOS IDT for their HDF-North observations (Thompson et al. 1998 in press). These discrepancies are presently being investigated

For the purposes of the version 1 data release and catalogs, we have adopted preliminary revised values of the photometric zeropoints for the F110W, F160W and F222M filters kindly provided by D. Calzetti of the STScI NICMOS group. We stress that these are PRELIMINARY values only, but we feel that there is sufficient reason to doubt the nominal pipeline photometric calibration that the use of new values, even preliminary ones, is justified. Here we present these new zeropoint values along with those from the calibration pipeline and those used by Thompson et al. for the HDF-North. In all cases, these are zeropoints in the AB magnitude system, such that

```
AB = zeropoint - 2.5 * log(n)
```

where n is the count rate (ADU per second) measured from the images. All HDF-S images, including those of the NICMOS field have been normalized, to counts per second, i.e. to an effective exposure time of 1 second. Therefore the zeropoints given above may be applied directly to measurements from the images without further rescaling for the exposure times. Actual exposure time varies with position across the image due to the dithering pattern, bad pixel masking, etc. The sum total of the integration times of all images used in the final drizzled mosaics is recorded in the TEXPTIME header keyword in each image.

Bandpass	Preliminary Revised Zeropoint	Pipeline Zeropoint	Thompson et al. HDF-North Zeropoint
F110W	22.75	22.89	22.68
F160W	22.77	22.85	22.80
F222M	21.80	21.89	-----

For the STIS-on-NICMOS image in the 50CCD (clear) bandpass, we adopt the nominal zeropoint from the calibration pipeline, identical to the value used for the primary HDF-South STIS field. We have no reason to question this zeropoint value at this time.

```
50CCD (STIS)    26.386
```

Note that the photometry keywords recorded in the headers of the Version 1 HDF-South NICMOS images (e.g. the PHOTFNU keyword) are those provided by the standard STScI calibration pipeline, and thus correspond to the zeropoints in the middle column above. I.e. they have *not* been revised to account for the new, preliminary calibrations described above.

WE EMPHASIZE THAT ABSOLUTE PHOTOMETRY FROM THE HDF-SOUTH NICMOS IMAGES MAY BE UNCERTAIN AT THE 10% LEVEL DUE TO THESE ZEROPOINT UNCERTAINTIES. We will provide updated information on photometric zeropoints on these web pages as it becomes available.

This page was last updated on March 11, 1999.

Flanking Fields Data Reduction / Technical Issues

Check the page with warnings and advisories before making any use of the data.

Information is available about the following topics:

- STIS 50CCD imaging
- WFPC2 imaging
- NICMOS imaging

STIS 50CCD imaging

Description of data products

Follow this link for a legend of the file names for the final reprocessed data.

General

The analysis and reduction of the STIS flanking fields proceeded in similar fashion as for the imaging of the Main STIS Field. Please read first the description of those observations, with particular emphasis on the description of the Flanking Field observations.

Observations

For Each of nine fields, STIS observation were made in parallel mode operation to the primary instrument WFPC2. After Guide Star Acquisition a "CR-SPLIT" 1200s exposure was followed by a 1300s "CR-SPLIT" exposure at a new dither (shifted) position, but at same roll angle. A second 'orbit' of observations immediately followed with two more dithered "CR-SPLIT" exposures of 1300s apiece.

```

Data Reduction/Technical Issues

The flanking fields were processed in very closely the same manner as described in the STIS Imaging section. These notes point out the exceptions.

- 1. The DARK calibration reference file used in the CALSTIS data reduction steps was constructed using a 'delta-dark' image appropriate for the epoch of the flanking field observations.
- 2. No cosmic ray rejection masks were used except those constructed within the XDITHERII DRIZ_CR processing.
- 3. There were no differences in the commanded rolls to the spacecraft between the dithered exposures. No significant roll offset was found in the processing. The only rotation applied in the combining process was the +5.4 degree rotation to North.
- 4. DRIZZLE drop-size used for the flanking fields was a "pixfrac" of 0.8.

WFPC2 imaging

Description of data products

The final data products for all of the WFPC2 Flanking Field observations are now available. The current version 1.0 (11/25/98 and 12/21/98) represents our best shot at a first combination of the WFPC2 data taken in the Hubble Deep Field South Flanking Fields.

Follow this link for a legend of the file names for the final reprocessed data.

For positions 1-9, images were taken in the F814W filter. Longer (9 orbit) flanking field observations were also taken when STIS was observing the NICMOS main field. These observations consist of both F606W and F814W images. Note that both data and weight images are presented in a single mosaic, with all four WFPC2 detectors combined onto the same image plane. The weight images represent the inverse of the variance predicted from a noise model at the mean sky level of the observations, taking into account masking of cosmic rays and hot pixels.

General

The analysis and reduction of the WFPC2 flanking fields proceeded in similar fashion as for the imaging of the Main WFPC2 Field. For information on the data reduction, please read first the technical information for the Main WFPC2 Field.

Combined Images

The combined images are the result of combining all individual exposures, optimally weighted for the background signal, and resampled to a pixel scale of 0.0498" using the "Drizzle" package developed by Fruchter and Hook and available in IRAF/STSDAS. The images are expressed in counts per second at a gain of 7. They have been rotated to have North approximately up (about 0.5 degrees from vertical). The coordinates of the images are set in the header WCS parameters, and can be retrieved for example via the IRAF task xy2rd. The absolute astrometry of the fields have not yet been converted to a standard astrometric system more precise than the HST Guide Star Catalog, and hence are uncertain by 1-2 arcsec. Work is underway to tie the fields to astrometrically measured stars kindly provided by the Naval Observatory. This work should be complete by the end of 1998.

The depth and coverage for each filter varies across the field of view, due to the variety of pointings that were combined together. The image depth wanes when approaching the edges of the area covered, as well as in a near-vertical seam between detectors which received much lower coverage than the central region of each chip. This variable depth is reflected in the image weights, described below.

As a consequence of the decreased image quality, the outer regions of each image are less reliable, especially in terms of cosmic ray rejection. Any oddly-shaped objects appearing in only one filter near the edge of the images presented here has a good probability of being a piece of an unrejected cosmic ray.

Images have been trimmed (set to zero) where the weight per pixel was zero. However there are a number of low-weight pixels around the edge that still have residual cosmic rays.

Photometry

WFPC2 detectors differ slightly in their sensitivity. The individual input images have been scaled to the response of the WF3 detector, thus the zero points determined for WF3 (at gain 7) apply. For reference, the most recent determination of the zero point for infinite aperture in the VEGAMAG system is:

```
F814W    21.66
```

Correlated Noise

Those planning to run detection and photometry software on these data should be aware that the noise is strongly correlated between adjacent pixels in the final drizzled images. Consult the main HDF-S web page for more details.

NICMOS imaging

CONSTRUCTION

Check here for information on the status of the NICMOS Flanking Field observations.

The Hubble Deep Field South Clearinghouse

As was the case with the northern HDF, there is likely to be lively interaction and competition among groups interpreting the HDF-S data and carrying out follow-up observations. Indeed, unlike the case for HDF-N, `follow-up' observations of HDF-S from ground- and space-based observatories began long before the primary HST observations were scheduled.

Here we provide a clearinghouse of links to web pages by various groups who are carrying out HDF-S research and observations. We invite anyone contemplating follow-up observations or detailed analysis to share information through this web page. The aim is to establish a forum for publicizing the status of followup work in order to avoid too much duplication, and to provide points of contact for cooperation/collaboration between various investigators. If you are interested in participating, please contact Mark Dickinson, Harry Ferguson, or Massimo Stiavelli.

You may also want to check out our page of HDF-S related publications and our HDF-North Clearinghouse.

Explanation of Search Functions.

Define Fields This option links to page which allows user to	Define criteria to select MDS fields which satisfy specified limits in Equatorial(J2000) or Galactic Coordinates, and also Depth of Stack in terms of limiting magnitude, and cosmic-ray split in terms of Minimum number of Exposures in the Red (F814W); Green (F606W); Blue (F450W); and Violet (F300W) wide-band filters used in the Survey.	Next click on Find Fields to list the MDS Fields satisfying the criteria specified in Define Fields.
	Specify a specific MDS field or object ID to directly access a known MDS field or object.	
Define Objects This option links to page which allows user to	Define criteria to select MDS objects which satisfy specified limits in magnitude, Half-light radius, Bulge to Disk Ratio, Signal-to-noise Index, and object classification.	Next click on Find Objects to list MDS objects satisfying the criteria specified in Define Objects in the MDS Fields selected by Define Fields.
	Specify a specific Equatorial coordinate(J2000) and search radius in seconds of arc to locate a specific object of known location.	
Define Image	Select the output image type when a object is selected. Default is gray-scale JPEG images with user definable stretch and quality. Can also select GIF (lossless); or the FITS file on CDROM with optional compression of .Z (UNIX) or .gz (gzip) type	
Clear Form	Reloads current form with default values.	
ReStart	Restarts search erasing all memory of defined fields, objects etc	

Hubble Space Telescope

Medium Deep Survey

The Medium Deep Survey (MDS) is an international project that uses the Hubble Space Telescope (HST) in Pure parallel mode to study the nature of faint galaxies in the deepest regions of the universe.

This is the gateway to get direct and full access to stacks and catalogs on the MDS CDROMS (2nd edition) created by the MDS group at Carnegie Mellon University (CMU) and archived on a Jukebox at the Space telescope Science Institute (STScI). These now non-proprietary post-HST-refurbishment observations cover the period from February 1994 to January 1998. More MDS cdroms will be released when available.

The released MDS database contains model fits for over 210,000 objects in over 450 WFPC2 fields, observed in most cases using the F814W (498 in I), F606W (358 in V), and for few in F450W (55 in B) photometric filters. Some fields overlap each other.

Over 60,000 galaxies have disk-like or bulge-like quantitative morphology classification based on maximum likelihood ratio, and over 9,000 have disk+bulge decomposition (after allowing for about 20% overlap in fields).

When considering using MDS galaxies for cross identification please note that the total survey area is just about one square degree. However when comparing with pointed observations with some other instrument with a field of view larger than about 15 arc min the probability of overlap could be much larger than (survey area in square degrees)/40253 because of coincidence of the interesting targets observed as the primary candidate by the HST and that instrument.

When considering using MDS galaxies for ground based follow up please note that the galaxies have a median half-light radius of 0.3 arc seconds. Only about 3,500 galaxies have an half-light radius larger than one arc-second of which only about 400 exceed two arc seconds.

Please also note that the calibrated stacks on the MDS CDROMS are in STSDAS/GEIS format written from a SUN UNIX machine. For example, VAX users will need to use sun2vax to convert these files. The MDS pipeline was developed on SunOS to use the GEIS format output from the WFPC2 calibration software. Files in a future edition of the MDS CDROMS maybe converted to system independent FITS.

Ratnatunga, K. U., Griffiths, R. E. & Ostrander, E. J. 1999,
The Top Ten List of Gravitational Lens Candidates from the HST Medium Deep Survey
Astronomical Journal **117** 2010-2023 . astro-ph/9902100

The observed regions cutout from HST WFPC2 images are 64 pixels of of the CCD or 6.4 arc seconds on a side.
All of the color images above were created using a fixed algorithm to transform the observed single filter F814W(R), F606W(G) and when available F450W(B) to color JPG. Although the color balance is probably not as pretty as images that may be created using interactive software procedures, these images can be inter-compared more realistically. Note however that the color of the lensing galaxies are not yellow at the center but a bright red. The yellow produced by color saturation is used to indicate brightness to otherwise flat images.

ABSTRACT

Quantitative morphological and structural parameters are estimated for galaxies detected in *Hubble Space Telescope* observations of WFPC2 survey fields. A modeling approach based on maximum likelihood has been developed for two-dimensional decomposition of faint undersampled galaxy images into components of disk and bulge morphology. Decomposition can be achieved for images down to F814W (I) ≈ 23.0, F606W (V) ≈ 23.8, and F450W (B) ≈ 23.3 mag in WFPC2 exposures of 1 hr. We discuss details of the fitting procedure and present the observed distributions of magnitude, color, effective half-light radius, disk and bulge axis ratios, bulge-to-(disk+bulge) flux ratio, bulge-to-disk half-light radius ratio, and surface brightness. We also discuss the various selection limits on the measured parameters. The Medium Deep Survey catalogs and images of random pure parallel fields and other similar archival primary WFPC2 fields have been made available via the Internet with a searchable browser interface to the database.

Key words: cosmology: observations—surveys

Abstract

Quantitative morphological and structural parameters are estimated for galaxies detected in Hubble Space Telescope observations of WFPC2 survey fields. A modeling approach based on maximum likelihood has been developed for two-dimensional decomposition of faint undersampled galaxy images into components of disk and bulge morphology. Decomposition can be achieved for images down to F814W(I)~23.0, F606W(V)~23.8, and F450W(B)~23.3 mag in WFPC2 exposures of 1 hr. We discuss details of the fitting procedure and present the observed distributions of magnitude, color, effective half-light radius, disk and bulge axis ratios, bulge-to-(disk+bulge) flux ratio, bulge-to-disk half-light radius ratio, and surface brightness. We also discuss the various selection limits on the measured parameters. The Medium Deep Survey catalogs and images of random pure parallel fields and other similar archival primary WFPC2 fields have been made available via the Internet with a searchable browser interface to the database.

Check the status of the SDSS archive servers.

What is the Sloan Digital Sky Survey?

Simply put, the Sloan Digital Sky Survey is the most ambitious astronomical survey project ever undertaken. The survey will map in detail one-quarter of the entire sky, determining the positions and absolute brightnesses of more than 100 million celestial objects. It will also measure the distances to more than a million galaxies and quasars. Apache Point Observatory, site of the SDSS telescopes, is operated by the Astrophysical Research Consortium (ARC).

The SDSS addresses fascinating, fundamental questions about the universe. With the survey, astronomers will be able to see the large-scale patterns of galactic sheets and voids in the universe. Scientists have varying ideas about the evolution of the universe, and different patterns of large-scale structure point to different theories of how the universe evolved. The Sloan Digital Sky Survey will tell us which theories are right -- or whether we have to come up with entirely new ideas.

The Sloan Digital Sky Survey (SDSS) is a joint project of The University of Chicago, Fermilab, the Institute for Advanced Study, the Japan Participation Group, The Johns Hopkins University, the Los Alamos National Laboratory, the Max-Planck-Institute for Astronomy (MPIA), the Max-Planck-Institute for Astrophysics (MPA), New Mexico State University, Princeton University, the United States Naval Observatory, and the University of Washington.

Funding for the project has been provided by the Alfred P. Sloan Foundation, the Participating Institutions, the National Aeronautics and Space Administration, the National Science Foundation, the U.S. Department of Energy, the Japanese Monbukagakusho, and the Max Planck Society.

www.sdss.org is a winner of the Griffith Observatory's Star Award

A Complete UV Atlas of Standard Stars

Chi-Chao Wu, Jinger Mo, D. Michael Crenshaw

* Observations * Data Reduction * Catalogues and Spectra * Acknowledgment *

Digital stellar atlases play an important role in astronomy. They provide the basic data needed for studies such as peculiar stars, composite systems (multiple systems, stellar clusters, and galaxies), automated spectral classification, testing of model stellar atmospheres, and interstellar or circumstellar extinction by dust. There are several atlases containing optical spectra obtained by modern detectors (Jacoby, Hunter & Christian 1984, Pickles 1985, and Silva & Cornell 1992). Together, these atlases contain good quality stellar spectra that cover the range 3500-9000 Å, at resolutions of 4-11 Å.

For many years, the International Ultraviolet Explorer (*IUE*) Observatory had generously granted us telescope time to build such an atlas in the UV. The three installments of the UV stellar spectral atlas are given in Wu et al. (1983,1991,1997). Wu et al. (1992) further provides the archival data for stars, clusters, and galaxies which are not given in the above installments.

This site delivers the final products of the *Complete UV Atlas of Standard Stars Project*. It provides the IUE NEWSIPS (New Spectral Image Processing System) MXLO (Low-Dispersion Merged Extracted Image FITS File) spectra (graphics and wavelength-flux table) of 514 stars, grouped in the following two new atlases.

- Complete Standard Star Atlas : 476 "Normal" Stars.
  - Standard Stars, sorted by Spectral Type
  - Standard Stars, sorted by Star Name (HD Number)
- Subluminous Star Atlas : 38 subdwarfs and white dwarfs.
  - Subluminous Stars, sorted by Spectral Type
  - Subluminous Stars, sorted by Right Ascension

jinger@stsci.edu

Project Information : Observations

* "Normal" Stars * Star Spatial Distribution * Star Spectral Type Distribution *

* "Normal" Stars

The observations, assembled here, were done mostly by Wu and his collaborators. Only a small number of images were taken from the IUE calibration programs and the other Guest Observers.

All observations were made in the low dispersion mode, with a spectral resolution of about 6 Å. For stars with a spectral type of F2 or earlier, both the short wavelength (1150-1975 Å) and long wavelength (1975-3200 Å) spectral regions were observed, while the short wavelength spectrum was generally not obtained for stars later than F2. In order to maximize the signal-to-noise (S/N) ratio, essentially all the spectra were taken in trail or pseudo-trail mode. Additionally, many observations have a complementary spectrum taken in the small aperture, such that higher exposure levels can be achieved for the spectral regions that tend to be underexposed.

Wu and his collaborators selected the candidate stars according to the following criteria: no known variability or peculiarity; not a member of a multiple system that has a companion that can introduce non-negligible flux to the observed spectrum; reliable MK spectral types and UBV photometry are available; low (or lower) interstellar extinction; and bright enough to give good S/N ratio at reasonable exposure times (generally 30 minutes or less), yet faint enough to give reliable trail rates (about 10 arcsec/sec or less). To provide additional cross checking against peculiarity and variability in the candidate stars, many of the spectral type and luminosity class combinations have two or more stars.

The observations provide a reasonably comprehensive coverage of the HR diagram. Note that many F, G, K dwarfs and giants have an appreciable number of observed stars. This is intended to include a range of metallicity to facilitate the modelling of the important main sequence turn-off components in older stellar populations.

The observations for the pervious atlas (Wu et al. 1983, 1991, 1997) were made during the period from March 1980 to September 1994. And the data presented in the three installments were processed by different versions of the IUESIPS and reduced by the software which was available in the *IUE Data Analysis Center* at the time. Thus, the previous atlas is lacking in internal consistency. Also, the noise characteristics, instrument parameters, and calibration which directly relate to the accuracy of the reported stellar fluxes, are better known now. The *IUE* Project has developed the NEWSIPS pipeline processing system which incorporates these latest improvements in the treatment of the *IUE* data. The Project has essentially reprocessed all the data with the NEWSIPS pipeline, and created the *IUE Final Archive*. Therefore, the time is ripe for the production of a new atlas, based on the data from the Final Archive, which will have the uniformly processed data and significantly improved accuracy for the stellar fluxes. For a detailed discussion of the Final Archive and the recalibration of the *IUE* spectra, see Nichols & Linsky (1996). For the new atlas, selected high quality spectra of a star will be merged to increase the S/N, and to repair spectral regions contaminated by reseaux, cosmic ray hits and other blemishes.

IUE Ultraviolet Spectral Atlas of Standard Stars

Computer Sciences Corporation

Project Information : Data Reductions

* MXLO Data * New Tools * Image Combine *

A new MXLO data reduction tool has been developed to carry out the IUE Standard Star Atlas Project under the IRAF (Image Reduction and Analysis Facility) environment. It facilitates reducing and analyzing data, generating the graphics (gif and ps format) and wavelength_flux (w_f) table for MXLO spectra, retrieving information from various related catologues, and so on.

The NEWSIPS Low-Dispersion Merged Extracted Image (MXLO) were retrieved from the IUE Final Archive, supported by the Multi-Mission Archive at STScI (MAST).

Features of The NEWSIPS MXLO Data

page top

- **FITS Table**
  The IUE NEWSIPS MXLO file is a 3-D FITS table, a binary table with fixed-length floating point vectors to contain the extracted fluxes and associated flags.
- **Data Points**
  The number of extracted points is always 640. Wavelength are linearly sampled to a uniform step size and measured in vacuum.
- **Aperture**
  Double aperture low-dispersion spectra will contain two rows, with one row for each aperture.
- **Absolute calibration**
  It convers to the absolute fluxes in the range of 1150-1980 Å for short-wavelength spectra and 1850-3350 Å for long-wavelength spectra.
- **Data Quality Flags** ν
  these flages indicate abnormal conditions in the data which can range from fairly minor to quite serious situations. The flags for the MXLO data should be examined carefully in order to ascertain whether or not a particular data point is good or bad. The data points with zero flag value indicate that the data have no know problem condition. In general, flag values of -8 or more negative are indicative of unreliable data. See Data Quality Flag Description for a detailed discussion.
- **Small Aperture Spectra**
  The absolute fluxes for small-aperture data are significantly less reliable than those of large-aperture data. Because centering errors in the small aperture can lead to large variations in the overall observed flux level for individual spectra, it is impossible to determine an absolute S/L ratio. Therefore, the average of S/L over all wavelengths is normalized to unity. *As a result, the small-aperture fluxes are known in a relative sense but not in an absolute one*. See NEWSIPS Aperture Response Corrections for detials.

A New IRAF Tool for the MXLO Data Reduction

page top

We assumed that the IUE MXLO data have been well-calibrated by the IUE NEWSIPS pipline.
And no additional calibration for MXLO data is made by this project.

The run sequence to genaerate the spctra and flux tables is

- **Convert Data Format**
  - convert the **IUE** spectra from the **MXLO** format to the STSDAS Table formats using the IUETOOL, an IRAF subpackage provided by R. Shaw and H. Bushouse at STScI.
  - convert 3D FITS table to 2D STSDAS table, including the following table columns.
    * w : wavelength
    * fL : flux of large aperture image
    * fS : flux of small aperture image
    * qL : data quality flag for large aperture image
    * qS : data quality flag for small aperture image
    * fLSc : averge combined flux of the large aperture and the scaled small aperture
    * qLSc : data quality flag for the averge combined image
- **Make Spectra**
  - wavelength ranges :
    * LWR : 1850 - 3200 Å
    * LWP : 1850 - 3200 Å
    * SWP : 1150 - 1980 Å
  - extract ralated information from image header and transfer it to graphics and tables.
  - make flux table
  - make graphics
  - combine images: utilized the STSDAS gcombine as a basic task to make image combine/merge. See *Image Combine* section for algorithms and parameter specifications.
    * Large Aperture Spectra
    * Double (Large and Small) Aperture Spectra

Image Combine: Algorithms and Parameters

page top

The input images to be combined are specified by a list. A list of input mask images, specified by the `masks' parameter, can be used to mask bad pixels before rejection operations. The mask images should have the same number and size as the input images.

- **For input images**, set
  - Masks
  - Scales and Image Statistics
  - Weights
  - Error Maps
- **For each output image line**,
  - Get input image lines
  - Reject masked pixels
  - Reject pixels using the specified algorithm
  - Combine remaining pixels using the weighted average or median
  - Write the combined image
- **Parameter Specifications**

Masks

The mask images, specified by the parameter, `masks', can be used to mask bad pixels before thresholding and rejection operations. The mask images should have the same number of and size as the input images. A mask image is always treated as of a boolean type. According to the IUE DQF, a zero value indicates a good pixel, while all non-zero mask values indicate a bad pixel.

The procedure for making the masks includes the following steps:

- retrieve the "QUALITY" flag from MXLO.
- make the mask image for each spectra : assumed a zero "QUALITY" value as good pixel.
- make the New Mask (optional).

Image Statistics and Image Scales

In order to combine images with rejection of pixels based on deviations from some average or median they must be scaled to a common level.

- LAp data only: No image scaling is preformed for the LAp absolutely- calibrated net spectra.
- SAp & LAp data: The small-aperture fluxes are known in a relative sense but not in an absolute one, and the absolute fluxes for small-aperture data are significantly less reliable than those of large-aperture data. Therefore, the SAp data scaling stage must perform prior to the image combining step.

The scaling stage includes the following steps:

- select wavelength region for estimating the average fL/fS
- make statistics for fL/fS within selected region
- scale fS and generate fSmed (the median scaled SAp Flux)

Weights

For each data point x(i), its own standard deviation sigma(i) represents its measured precision. The most probable value for the mean is the weighted average of the data points, where each data point is weighted inversely by its own variance sigma(i)**2 in sum.

Two types of weighting scheme are applied to process the MXLO data

- Uniform Weighting :
  - Weights are constant for all pixels of each input image.
  - This uniform weighting scheme is adopted to combine a set of LAp spectra or a set of combined LAp and SAp data. The SAp data. The exposure time is seleted as the only weighting factor.
- Pixel-wise Weighting
  - Weight of a data point is the reciprocal of the variance sigma(i)**2 at that pixel.
  - An input error map, associated with each input image must be specified. The sigma is the scaled error taken from the input *error image*.
  - The "pixel-wise" weighting scheme is adopted to combine the SAp and the LAp data.

Error Maps

The error map applied for our code is consist of two types of uncertainty factor :

- "sigma" spectra : It is known that the MXLO "sigma" spectra indicate the estimated error in the extracted fluxes.
- median scaled factor of fL/fS over a select range, where fL and fS are the flux for LAp and SAp, respectively.

The error maps would then be set as

- For LAp : error map = sqrt (sL)
- For SAp : error map = sqrt (sS * med)

where sL and sS is the "sigma" spectrum for LAp and SAp, respectively. The "med" is the median scaled factor of fL/fS over the selected range. And the "sqrt" here is the square root oprator.

Rejection Algorithms

This stage rejects pixels using sigma clipping about the weighted average. The weighted average (trimmed mean) is used to represent the expected signal level. Values deviating from the expected signal level by more than the specified sigma threshold factors (hsigma and lsigma) are rejected.

- Case 1: input error images are available.
  The noise characteristics of the input images are well represented by the noise values stored in each pixel of the error images.
  This case corresponds to the "errcrrej" rejection in the task "gcombine" .
- Case 2: use robust sigmas compute a sigma, robust against the effects of unidentified outliers on the estimate of the sigma.
  This case corresponds to the "rsigcrrej" rejection in the task "gcombine" .

(see the help file of task "gcombine" for details)

Combining

After all the steps of masking pixels, scaling, and applying a rejection algorithms, the remaining pixels are combined. The pixels may be combined by computing a weighted average. The weighted average, however, is the only adopted option for our project, since the image number for image combine is less than 5. In most cases, it is 2 or 3.

One of the following two weighting scheme must be specified for making the weighted average combine.

- `weight'="exposure":
  The uniform weights are specified in the same way as the scale factors. The "exposure" option in the intensity scaling uses the value of the image header keyword specified by the `expname' keyword. As implied by the parameter name, this is typically the image exposure

time since DN levels are linear with the exposure time in SEC Vidicon.

- `weight'="pixelwise";
  The weight is the reciprocal of the sigma**2, where the sigma is the scaled error taken from the input error image.

IUE Ultraviolet Spectral Atlas of Standard Stars

Computer Sciences Corporation

Project Information : Final Products: Catalogues and Spectra

* Catalogues * Spectra and Flux Tables *

Catalogues

page top

This page gives some basic information associated with the 476 standard stars, including the HD number, star name, spectral type and luminous class, reference key number for spectral_type and the luminous_class, RA (Right Ascension) and Dec (Delination), V magnitue, remarks, B-V, and E(B-V).

For each star, an UV spectra page can be accessed through the HD number or the star name in the atlas page. The spectra page provides the informaton of the IUE observations and the outputs of the IUE data processing. The outputs include spectral plots and the w_f tables for each observation. A weighted combined spectrum is made for each camera, if two or more observations are available for the object or the mxlo is a double (large and small) aperture image.

- **Columns Description**

Cloumn	Units	Explanations
HD		HD number
Name		name of the star
Sp_Type		spectral type
Ref		key to data source for spectral type
RA	hh:mm:ss	right ascension (1950.0)
DEC	dd:mm:ss	declination (1950.0)
V	mag	V magnitude
Remarks		remarks on duplicity / variability
B-V	mag	B-V colour index
E(B-V)	mag	color excess on B-V

- **Reference Sources of Spectral Type**

  The spectral type in this page is assembled from various sources. The column Ref indicates the key number to the data source for the spectral type. Those reference sources are listed in Table 2.

Key Number	Peference Source
1	Morgan and Keenan 1973
2	Johnson and Morgan 1953
3	Walborn 1982
4	Walborn 1973
5	Walborn 1972
6	Lesh 1968
7	Lesh 1972
8	Garrison, Hiltner and Schild 1977
9	Morgan, Code and Whitford 1955
10	Cowley, Clwley, Jaschek and Jaschek 1969
11	Keenan and Pitts 1980
12	Keenan and Pitts 1981
13	Jaschek 1980
14	Buscombe 1984
15	Hoffleit 1982
16	O'Connell 1973

- **Star Coordiates: RA & DEC**

  The RA and DEC are retrieved from the *SAO* (Smithsonian Astrophysical Observatory) Star Catalog

- **Photometric Data**

  The source of the photometric data are taken from the *Catalogue of Mean UBV Data on Stars*, an on-line catalog from J.-C. Mermilliod and M. Mermilliod, 1998. In the column Remarks, following the notation of the UBV catalog, an "A" indicates that the star has a close neighbor and that the V magnitude is only for the brighter component. On the other hand, an "AB" indicates that the V magnitude is the combined brightness of the both components. The column E(B-V) is observed B-V (in column 9) minus the intrinsic B-V from FitzGerald (1970). The E(B-V) values assume that the intrinsic B-V's for higher luminosity O stars are the same as main sequence stars of the same spectral type. The computations of E(B-V) for spectral types and luminosity classes, which have no intrinsic B-V in FitzGerald, used interpolated values of B-V.

UV Spectra

page top

This section presents the **Graphics** and **Flux Tables** of the UV spectra of the IUE Standard Stars, the outputs of the data processing from the IUE NEWSIPS MXLO data. The star information, appeared on the page top, is transferred from the Atlas Page.

For each observation, the output of the data processing includes a pair of spectral graphics (a gif file and a ps file) and a w_f (wavelength_flux) text table. Users can access these files by pointing to any of the (gif), (ps) or (w_f) files.

- **Description of the MXLO Image Log**
  - Image : camera(LWR/LWP/SWP) plus image sequence number
    * (gif) - graphics of mxlo spectrum in GIF format
    * (ps) - graphics of mxlo spectrum in PostScript format
    * (ps) - graphics style (color, line style, and marker)

MXLO Data	Large Aperture Spectra	Small Aperture Spectra
Spectra	Black Solid Line	Violet Dashed Line
Bad Data Points	Red Cross	Blue Asterisk

  - (w_f) - mxlo wavelength_flux table in ASCII text format
    * w : wavelength
    * fL : flux of large aperture image
    * qL : DQF for large aperture image
    * fS : flux of small aperture image
  - Ap : aperture (Large/Small)
  - N : number/T
    * number - the number of exposure along the major axis of the large aperture
    * T - trail mode observation
  - Exp : exposure time in seconds
  - E/C/B : DN (Data Number) level of E/C/B, comment by Resident Astronomer of the IUE observatory
    * E - maximum Emission
    * C - maximum Continuum
    * B - mean Background

- **Combined Image**
  - Single Aperture Exprosure & Double Aperture Exprosure
    * Single Aperture Exprosure : A weighted combined spectrum is given for each camera, if two or more Large aperture images are available. The weighting factor is the total exposure time.
    * Double Aperture Exprosure :
  - Description of the Combined Image Log
    * (gif) - combined spectrum in GIF format
    * (ps) - combined spectrum in PostScript format
    * (w_f) - combined wavelength_flux table in ASCII text format

Table Column	Single Aperture Spectra	Double Aperture Spectra
wavelength	w	w
flux (of combined spectra)	fcomb	fLSc
DQF (of combined spectra)	qcomb	qLSc

- **Notes**
  - The ps graphics have the same wavelength range and scale as those in *The IUE Ultraviolet Spectral Atlases*, published in the NASA NEWLETTER No.22, 1983 and No.43, 1993. Users may browse and/or print the ps file from Netscape Navigator directly.
  - Users may use GSview as a PostScript files viewer under
    * OS/2
    * MS-Windows 3.1/Win32s
    * MS-Windows 95/98
    * MS-Windows NT for
    * IBM WebExplorer
    * NCSA Mosaic
    * Netscape Navigator
    * Internet Explorer
  - For the double aperture spectra, a scaled image for small aperture image is overploted onto the large aperture spectrum. Users must keep in mind, the small-aperture fluxes are known in a relative sense but not in an absolute one, and the absolute fluxes for small-aperture data are significantly less reliable than those of large-aperture data.

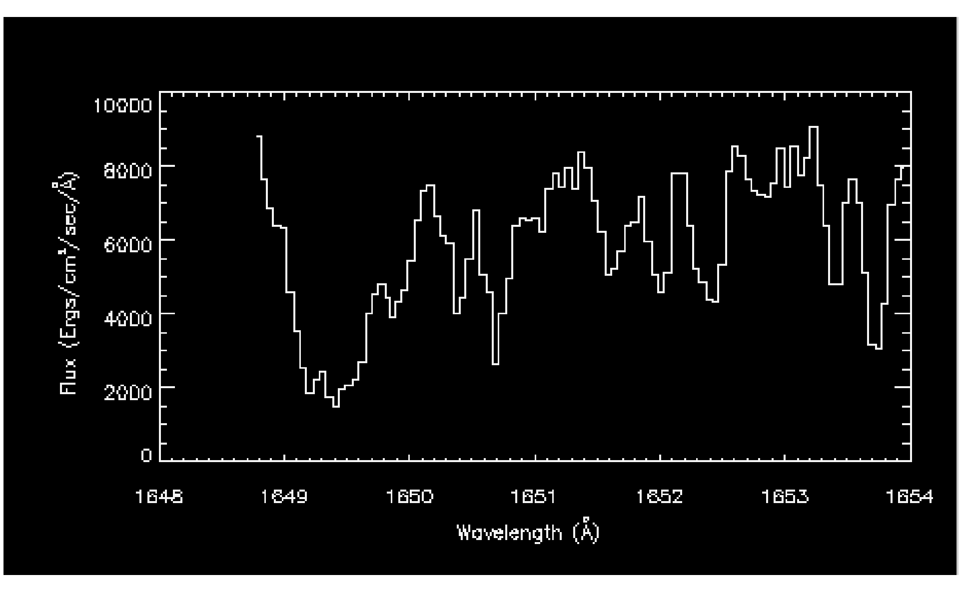
The Alpha Canis Majoris (Sirius) Spectral Atlas



The primary reference for the *Copernicus* Spectral Atlas of Sirius is Rogerson, J. B., (1987ApJS...63..369R). The summary information that follows is taken from that reference.

The observations obtained to construct this atlas were obtained primarily during the periods 1977 March 5-8, 1977 March 12-16, and 1977 March 18-April 5. There were several gaps in the coverage of this data; these were filled in with observations obtained during the period 1981 February 8-9. A gap starting at 2292.7 Å was overlooked. The spectral atlas covers wavelengths from 1649 Å to 3170 Å, with a spectral resolution of 0.1 Å. The scans were made in the V1 detector. A complete description of the *Copernicus* science instrument may be found in Rogerson *et al.* (1973ApJ...181L..97R).

Wavelengths were corrected for Doppler shifts due to (a) the heliocentric radial velocity of Sirius, (b) the Earth's heliocentric velocity in the direction of Sirius, and (c) the component of the satellite geocentric orbital velocity in the direction of Sirius. The counts from the source were corrected for counts due to cosmic rays and trapped charge particles, guiding errors and scattered light within the spectrometer. No correction was made for the wavelength variations in the spectrometer sensitivity.

The atlas is a compilation of 36 separate scans of specific spectral regions. There are a total of six files, numbered 2-7 (following the original NSSDC file numbering scheme). File 2 contains the counts for the vacuum spectrum; file 3 contains the normalizing continuum and scattered light values for the vacuum spectrum; file 4 contains the line identification table for the vacuum spectrum; file 5 contains the counts for the air spectrum; file 6 contains the normalizing continuum and scattered light values for the air spectrum; and file 7 contains the line identification table for the air spectrum.

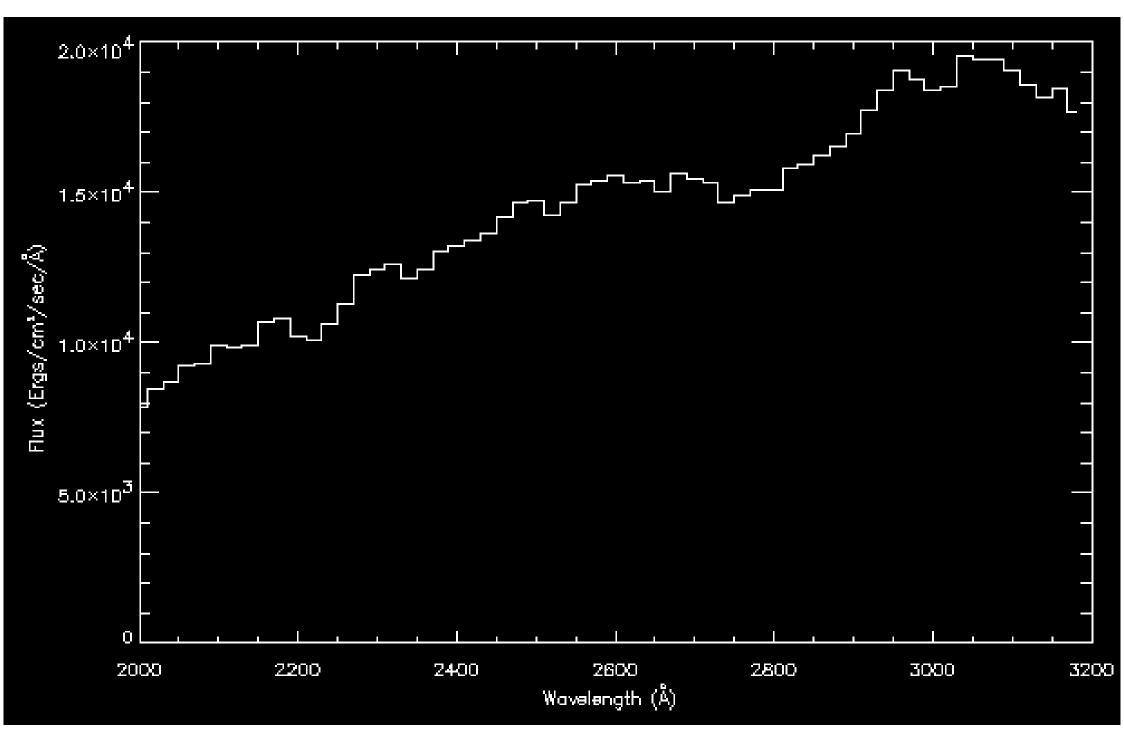
The Alpha Lyrae (Vega) Spectral Atlas



The primary reference for the *Copernicus* Spectral Atlas of Vega is Rogerson, J. B., (1989ApJS...71.1011R). The summary information that follows is taken from that reference.

The observations used to construct this atlas were obtained during 1975 September 12-21 and 1975 September 27-October 7. Several gaps were filled in on 1976 April 20. The spectral atlas covers wavelengths from 2000 Å to 3187 Å (first order), with a spectral resolution of 0.1 Å. The scans were made in the V1 detector. A complete description of the *Copernicus* science instrument may be found in Rogerson *et al.* (1973ApJ...181L..97R).

Wavelengths were corrected for Doppler shifts due to (a) the heliocentric radial velocity of Vega, (b) the Earth's heliocentric velocity in the direction of Vega, and (c) the component of the satellite geocentric orbital velocity in the direction of Vega. The counts from the source were corrected for counts due to cosmic rays and trapped charge particles, guiding errors and scattered light within the spectrometer. No correction was made for the wavelength variations in the spectrometer sensitivity.

The atlas is a compilation of 23 separate scans of specific spectral regions. There are four files relating to these observations. The file numbers start at 2 following the original naming convention used at NSSDC. File 2 contains the air spectrum; file 3 is the normalization continuum and estimated scattered light; file 4 contains the equivalent flux values in 20 Å intervals in ergs/cm²/s/Å; and file 5 contains the table of line identifications.

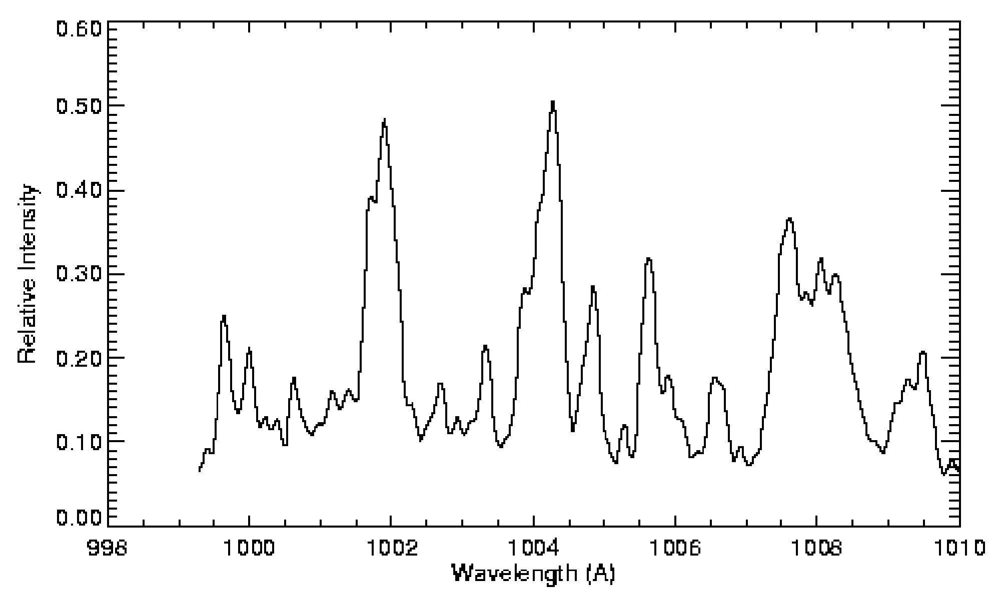
The Beta Orionis Spectral Atlas



The primary reference for the *Copernicus* Spectral Atlas of Beta Orionis is Rogerson, J. B. and Upson, Walter L., (1982ApJS...49..353R). The summary information that follows is taken from that reference.

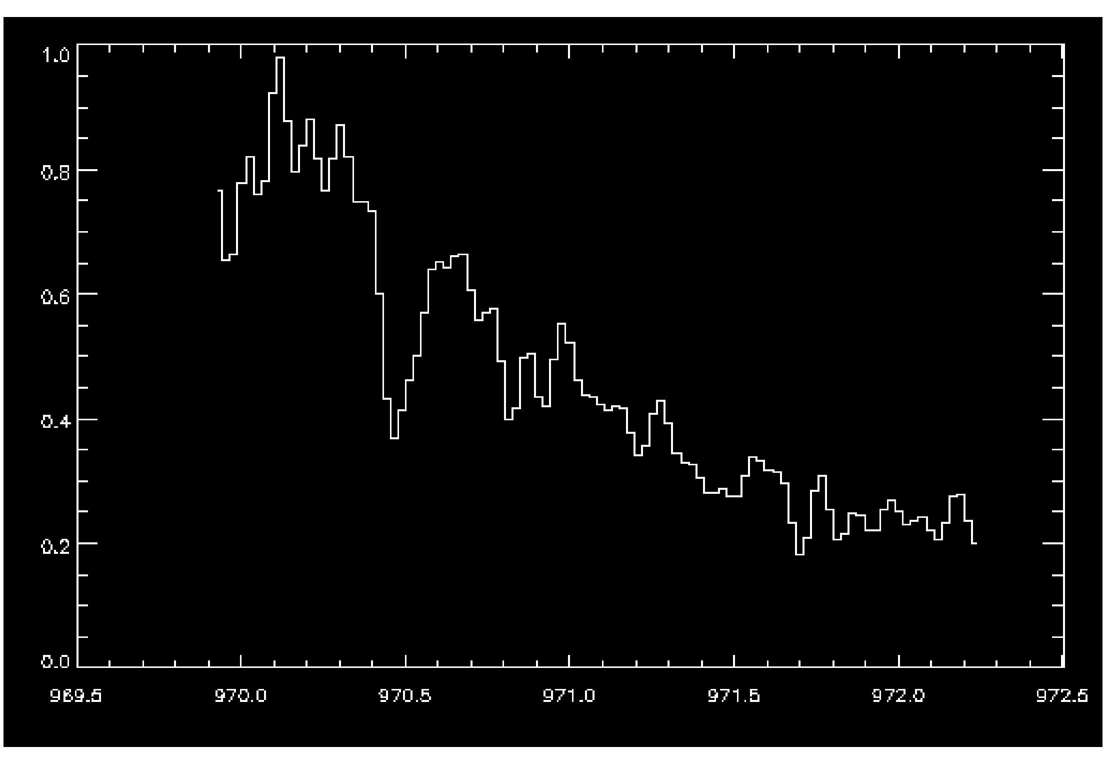
The observations obtained to construct this atlas were obtained primarily during the periods between 1974 December 3-17. Additional observations were obtained on 1975 January 19 to replace some unusable measurements. The spectral atlas covers wavelengths from 999.3 Å to 1420.1 Å (second order) and 1416.5 Å to 1561.1 Å (first order), with a spectral resolution of 0.1 Å in first order and 0.05 Å in second order. The scans were made in the U1 detector. A complete description of the *Copernicus* science instrument may be found in Rogerson *et al.* (1973ApJ...181L..97R)

Wavelengths were corrected for Doppler shifts due to (a) the heliocentric radial velocity of Beta Ori, (b) the Earth's heliocentric velocity in the direction of Beta Ori, and (c) the component of the satellite geocentric orbital velocity in the direction of Beta Ori. The counts from the source were corrected for counts due to cosmic rays and trapped charge particles, guiding errors and scattered light within the spectrometer. No correction was made for the wavelength variations in the spectrometer sensitivity.

The atlas is a compilation of 29 separate scans of specific spectral regions. There are a total of two files relating to the Beta Ori Spectral Atlas. File 1 is the 2nd order continuum and estimated scattered light, and file 2 is the first order continuum and estimated scattered light.

FILENAME	ROWS	FIELDS	WVE_FRST	WVE_LST	TYPE
betaori1.fts	19987	6	999.281	1420.151	2nd order
betaori2.fts	2779	6	1416.514	1561.120	1st order

The Gamma Pegasi Spectral Atlas



The primary reference for the *Copernicus* Spectral Atlas of Gamma Pegasi is Rogerson, J. B., (1985ApJS...57..751R). The summary information that follows is taken from that reference.

The observations used to construct this atalas were obtained during four different periods: 1978 July 27, 1978 October 30-November 22, 1978 December 16-22, and 1979 December 10-17. The spectral atlas covers wavelengths from 969.9 Å to 1430.2 Å (second order) and 1417.0 Å to 1501.4 Å (first order), with a spectral resolution of 0.1 Å in first order and 0.05 Å in second order. The scans were made in the U1 detector. A complete description of the *Copernicus* science instrument may be found in Rogerson *et al.* (1973ApJ...181L..97R).

Wavelengths were corrected for Doppler shifts due to (a) the heliocentric radial velocity of Gamma Peg, (b) the Earth's heliocentric velocity in the direction of Gamma Peg, and (c) the component of the satellite geocentric orbital velocity in the direction of Gamma Peg. The counts from the source were corrected for counts due to cosmic rays and trapped charge particles, guiding errors and scattered light within the spectrometer. No correction was made for the wavelength variations in the spectrometer sensitivity.

Since this star is a Beta Cephei variable with a period of 0.1518 days and velocity amplitude of 5 km/s, an additional correction was made for the Beta Cephei type variations. This correction is described in detail in the text.

The atlas is a compilation of 22 separate scans of specific spectral regions. There are a total of two files relating to the Gamma Peg Spectral Atlas. File 1 is the 2nd order spectrum and file 2 is the first order spectrum.

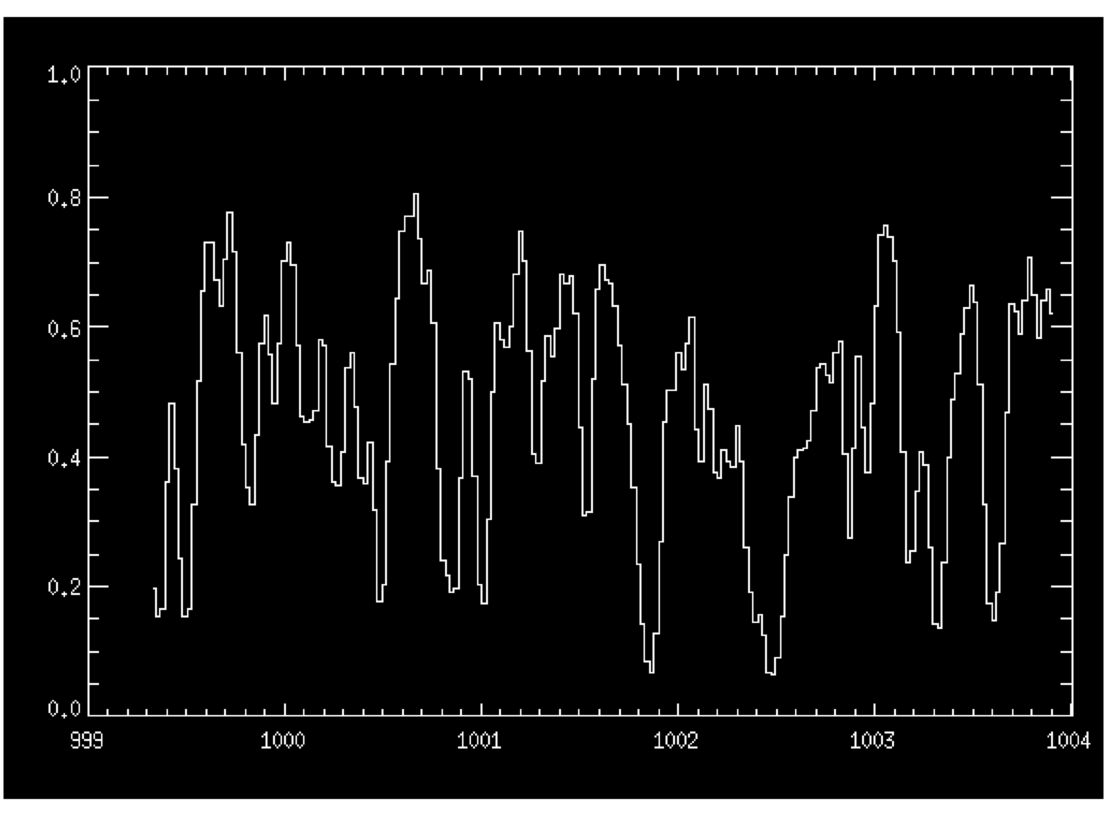
The Iota Herculis Spectral Atlas



The primary reference for the *Copernicus* Spectral Atlas of Iota Hercules is Upson, Walter L. and Rogerson, J. B., (1980ApJS...42..175U). The summary information that follows is taken from that reference.

The observations obtained to construct this atlas were obtained primarily during the periods between 1974 July 11 and September 12. The spectral atlas covers wavelengths from 993.3 Å to 1422.2 Å (second order) and 1417.9 Å to 1467.7 Å (first order), with a spectral resolution of 0.1 Å in first order and 0.05 Å in second order. The scans were made in the U1 detector. A complete description of the *Copernicus* science instrument may be found in Rogerson *et al.* (1973ApJ...181L...97R).

Wavelengths were corrected for Doppler shifts due to (a) the heliocentric radial velocity of Iota Her, (b) the Earth's heliocentric velocity in the direction of Iota Her, and (c) the component of the satellite geocentric orbital velocity in the direction of Iota Her. The counts from the source were corrected for counts due to cosmic rays and trapped charge particles, guiding errors and scattered light within the spectrometer. No correction was made for the wavelength variations in the spectrometer sensitivity.

The atlas is a compilation of 29 separate scans of specific spectral regions. There are a total of two files relating to the Iota Her Spectral Atlas. File 1 is the 2nd order spectrum and file 2 is the first order spectrum.

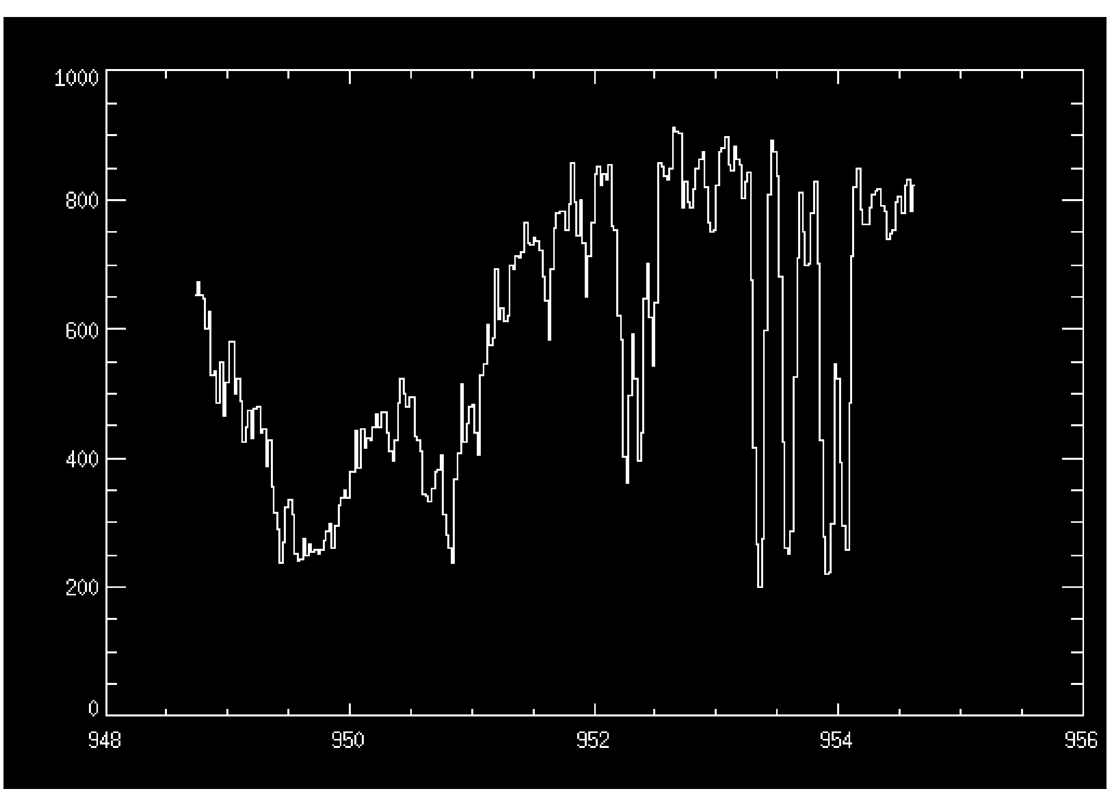
The Tau Scorpii Spectral Atlas



The primary reference for the *Copernicus* Spectral Atlas of Tau Scorpii is Rogerson, J. B. and Upson, Walter L., (1977ApJS...35...37R). The summary information that follows is taken from that reference.

The observations obtained to construct this atlas were obtained primarily during the periods between 1973 July 2 and August 27. The spectral atlas covers wavelengths from 948 Å to 1420.6 Å (second order) and 1418.2 Å to 1560.2 Å (first order), with a spectral resolution of 0.1 Å in first order and 0.05 Å in second order. The scans were made in the U1 detector. A complete description of the *Copernicus* science instrument may be found in Rogerson *et al.* (1973ApJ...181L..97R).

Wavelengths were corrected for Doppler shifts due to (a) the heliocentric radial velocity of Tau Sco, (b) the Earth's heliocentric velocity in the direction of Tau Sco, and (c) the component of the satellite geocentric orbital velocity in the direction of Tau Sco. The counts from the source were corrected for counts due to cosmic rays and trapped charge particles, guiding errors and scattered light within the spectrometer. No correction was made for the wavelength variations in the spectrometer sensitivity.

The atlas is a compilation of 32 separate scans of specific spectral regions. There are a total of two files relating to the Tau Sco Spectral Atlas. File 1 is the 2nd order spectrum and file 2 is the first order spectrum.

ERRATUM: Note that there is a slight wavelength error in both file 2 and the published paper for wavelengths greater than 1499.9 Å. The corrected values are obtained using the relation

W(correct) = 1.0014523 * W(table) - 2.2656.

OAO-3 "Copernicus" High Resolution Spectral Atlases

During the *Copernicus* mission several stars were observed intensively with the high-resolution spectrometers to obtain as complete wavelength coverage as possible. Ultraviolet high resolution spectral atlases were constructed for six stars: Alpha CMa (Sirius), Alpha Lyr (Vega), Beta Ori (Rigel), Gamma Peg, Iota Her, and Tau Sco.

The atlas data were delivered to GSFC by the Copernicus Project at Princeton University in the early 1980s. The data are now available in FITS binary table format and can be selected from the following table. Each star also has a corresponding journal article describing the details of the extraction and analysis, including identification of spectral features. Summary information on the atlas contents and file descriptions are included on the pages for each atlas.

Star	V	Sp Type	Wavelength (Å)	Resol (Å)	Reference
Alpha CMa	-1.46	A1 Vm	1650-3170	0.10	Rogerson, *Ap.J. Supp*, 63, 369, 1987
Alpha Lyr	0.03	A0 Va	2000-3185	0.10	Rogerson, *Ap.J. Supp*, 71, 1011, 1989
Beta Ori	0.16	B8 Ia	999-1420 1420-1560	0.05 0.10	Rogerson & Upson, *Ap.J. Supp*, 49, 353, 1982
Gamma Peg	2.82	B2 IV	967-1430 1430-1500	0.05 0.10	Rogerson, *Ap.J. Supp*, 57, 751, 1985
Iota Her	3.80	B3 IV	999-1420 1420-1470	0.05 0.10	Upson & Rogerson, *Ap.J. Supp*, 42, 175, 1980
Tau Sco	2.84	B0 V	949-1420 1420-1560	0.05 0.10	Rogerson & Upson, *Ap.J. Supp*, 35, 37, 1977

The files may be read with any FITS reader that supports the binary table format. The IUEDAC procedure IFITSRD is a generic IDL based FITS reader which can be used to read these files.

The *Extreme Ultraviolet Explorer* Stellar Spectral Atlas

N. CRAIG, [1] M. ABBOTT, [1] D. FINLEY, [1] H. JESSOP, [1] S. B. HOWELL, [2] M. MATHIOUDAKIS, [3] J. SOMMERS, [1] J. V. VALLERGA, [1] AND R. F. MALINA [1, 4]

Received 1997 February 11; accepted 1997 May 5

ABSTRACT

We present an atlas of extreme ultraviolet (EUV) spectra of 95 bright stellar sources observed between 1992 July and 1996 June with the *Extreme Ultraviolet Explorer* (*EUVE*) spectrometers. These data are taken in the short- (SW; 70–190 Å), medium- (MW; 140–380 Å), and long-wavelength bandpasses (LW; 280–760 Å) at roughly 0.5, 1, and 2 Å resolution, respectively. We describe the spectrometers and detail the procedure used to reduce the observational data to spectra. The atlas is grouped by the type of source: O–A stars, F–M stars, white dwarfs, and cataclysmic variables. We present a brief overview of the general nature and EUV spectral distribution of each group and present accompanying notes and individual spectra for each source. We show selected F–M sources in more detail with identifications of the brightest spectral lines illustrating the characteristics of the EUV spectra of stars of various temperatures. The current study is the most complete compilation to date of aggregate spectra of bright EUV stellar sources.

Subject headings: atlases—instrumentation: spectrographs—ultraviolet: stars—white dwarfs

§1. INTRODUCTION

The *Extreme Ultraviolet Explorer* (*EUVE*) satellite is a NASA Explorer-class mission devoted to acquiring astronomical data in the wavelength range from 70 to 760 Å. The satellite was launched on 1992 June 7. The *EUVE* science payload consists of three co-aligned, imaging telescopes, a deep survey/spectrometer (DS/S) telescope, and supporting electronic subsystems. A full description of the science instrumentation is presented by Bowyer & Malina (1991) and Welsh et al. (1990).

The three imaging telescopes were designed to survey the entire sky in bandpasses centered at ~100, 200, 400, and 600 Å. The DS/S telescope, which points orthogonally to the imaging telescopes, was designed primarily to collect a strip of deep observations along the ecliptic during the all-sky survey. The Deep Survey (DS) part of this telescope images half of the telescope mirror area in ~100 and 200 Å bandpasses, while the rest of the light is directed to the three spectrometers. All of the science instruments were built under contract from NASA Goddard Space Flight Center by the Space Astrophysics Group, part of the Center for EUV Astrophysics at the University of California, Berkeley. An overview of the mission was presented in Bowyer, Malina, & Marshall (1988) and Bowyer & Malina (1991).

Since the completion of the all-sky survey, the primary focus of the mission has been to acquire spectroscopic observations of specific targets for guest investigators sponsored through a NASA Guest Observer Program. A simultaneous DS image of the target is also obtained with each pointed spectroscopic observation. These data sets are proprietary to the Guest Investigator for 6 months following the observation, after which they are placed in the *EUVE* Archive and become publicly available.

The most recent catalog resulting from the all-sky survey is published in Bowyer et al. (1996). A set of early, brief reviews of some of the scientific results from both imaging and spectroscopic data taken since launch has also been published in Vennes et al. (1995a). Also, see many of the papers in Bowyer & Malina (1996).

In this paper we present an atlas of EUV spectra of 95 stellar sources taken from the *EUVE* Public Archive. In § 2.1, we describe the spectrometers and detail the procedure used to reduce the observational data to spectra. Sections 3–6 contain the atlas, grouped by the type of source: O–A stars, F–M stars, white dwarfs, and cataclysmic variables. For each type, we present a brief overview of the EUV appearance of the objects followed by notes about each source and individual spectra.

§2. THE *EUVE* SPECTRAL ATLAS

§2.1. *Instrumentation and Data Reduction*

§2.1.1. *The EUVE Spectrometers*

EUVE contains three slitless, imaging spectrometers; each receives light from one-sixth of the DS/S telescope collecting area (the other one-half of the light goes to the DS detector). The short-wavelength spectrometer (SW) has a bandpass of 70–190 Å and a resolution of roughly 0.5 Å. The medium-wavelength spectrometer (MW) covers 140–380 Å at roughly 1 Å resolution, and the long-wavelength spectrometer (LW) covers 280–760 Å at roughly 2 Å resolution. For a detailed review of the spectrometer instrumentation, see Abbott et al. (1996) and references therein. We give a brief summary here.

The DS/S telescope uses grazing incidence optics and has a Wolter-Schwarzschild Type II f/3.4 primary with a 40 cm diameter. The spectrometer gratings have variable line spacing and are placed in the converging beam. Each spectrometer has a field of view of 5°.25 in the dispersion direction and 2°.1 perpendicular to it (the latter direction is also known as the imaging direction).

The MW and LW spectrometer bandpasses include the bright geocoronal lines He II 304 Å (in both first and second order) and He I 584 Å. If unrestricted, this resonantly scattered solar radiation would dominate the background of these two spectrometers, seriously degrading the instrument sensitivity. Therefore, wire grid collimators are used to limit the contamination spatially from the diffuse background. The total response function of the collimators is similar to a triangular vignetting function, which restricts the field of view in the dispersion direction to about 0°.3 FWHM, while leaving the field of view in the imaging direction unchanged. The SW spectrometer has no such collimator. To remove out-of-bandpass scattered light further from such sources as the geocoronal H Lyα airglow feature, the spectrometers contain filters. The SW spectrometer contains a single Lexan/boron filter to restrict the throughput at wavelengths longer than 200 Å. The MW and LW spectrometers each have an aluminum filter.

EUVE uses microchannel plate (MCP) detectors for all of its instruments (Siegmund et al. 1984), which provides photon counting and a high efficiency. The detectors have a diameter of 50 mm and a spatial resolution of 120 μm. The detector electronics produce a 2048 × 2048 pixel image with pixels approximately 29 μm on a side, corresponding to 4″.5 in the imaging direction and 11″ in the dispersion direction. The image of the aperture covers a circular region roughly 1750 pixels in diameter (varying slightly from detector to detector).

§2.1.2. *Data Analysis and Display*

All data reduction was performed using the standard software (the EUV package) provided to researchers by the *EUVE* Guest Observer (EGO) Center. This package runs in the IRAF environment (Tody 1986). We used an identical process to that performed at the EGO Center to reduce observations nominally before delivering them to guest investigators, except for the spectral extraction and subsequent steps. We now summarize this process.

The pipeline task CEP in the EUV package was used to remap the detected events to a wavelength and imaging angle (the latter is the angular distance in the imaging direction of a photon from the center of the source). When possible, we used a source position measured from a DS image of the source that was remapped onto the sky. This reduced the possibility of systematic errors from inaccurate target coordinates or telescope flexure. We used the most recent version of the spectrometer wavelength calibration available from the EGO Center, which is detailed in Abbott et al. (1996).

The resulting remapped event list was then filtered to remove times when the data were of lower quality. We removed data taken when the source was blocked by Earth by eliminating all times when the DS/S telescope was pointed in a direction more than 102° from the local spacecraft zenith; this corresponds to an altitude of 365 km above Earth's limb, where atmospheric absorption becomes significant in the LW spectrometer. We removed times of high background rate by eliminating data taken when the detector count rate was above 80 counts per frame in the SW spectrometer, 130 counts per frame in the MW spectrometer, and 150 counts per frame in the LW spectrometer. [5] We discounted intervals when the detectors were turned off by eliminating times when the count rates were less than 3 counts s^{-1} in all of the spectrometers.

The remaining events were binned into a spectral image, which is linear in wavelength along one axis and linear in imaging angle along the other. Where multiple observations of a source were present in the *EUVE* archive, we summed the images from the separate observations into a composite image if doing so substantially improved the signal-to-noise (S/N) ratio of the spectrum. For certain bright continuum sources susceptible to distortions caused by fixed-pattern noise on the detectors, we included only observations that had been carried out using dithering, a technique that reduces the effect of the fixed-pattern noise on the data.

Many *EUVE* sources have a variable flux; examples include binary systems showing orbital variations or eclipses, flaring events in active stellar atmospheres, and effects from stellar rotation. Analysis of the time behavior of the EUV spectrum can lead to important results. In this atlas, however, we show only aggregate spectra, summed in time over one or more observations. In some cases, the detailed descriptions of each source in §§ 3–6 describe some of the published results of timing analysis.

Spectral extraction was done using a simple rectangular aperture. The remapping performed by the CEP task produces spectra that have a nearly constant imaging angle in the spectral image, so it was not necessary to trace the spectra. The spectra chosen for this atlas were all relatively bright, so we centered the aperture by visually locating one or more spectral lines in the spectral image. We summed the pixels in a 24 pixel wide strip centered on the spectrum and subtracted a background formed by averaging the counts in large regions on either side of the spectrum, taking care to avoid including any hot spots or other detector features in the background estimate.

Since the *EUVE* detectors oversample the resolution of the spectrometers in wavelength (containing approximately 7 pixels per resolution element), we blocked or averaged the extracted spectra to improve the S/N. The amount of blocking performed varies among the different types of sources appearing in the atlas and will be described in detail in the figure caption of each spectrum.

We determined the effective exposure time for each observation by computing the total valid time in our data quality filters, correcting for the effects of dead time and primbsching. [6] Because of the filtering, and because the *EUVE* detectors are allowed to turn off independently to prevent damage during times of very high count rate (typically caused by a high background from passage through the South Atlantic Anomaly), most observations have slightly unequal exposure times for each spectrometer.

The three spectra for each source were fluxed by dividing them by their effective exposure times, by the effective area of the appropriate spectrometer, and by their bin widths. *EUVE* spectra contain several overlapping orders. The atlas makes use of two techniques to deal with order effects. For the O–M stars in §§ 3 and 4, flux at second and higher orders in the spectra was simply ignored. In those cases, the higher order features will appear in the spectra with incorrect fluxes (usually underestimated) because of having been divided by the first-order effective areas. For the B stars in Figures 1 and 2, which have no significant flux at short wavelengths, higher order contamination of the spectrum is negligible. In the later spectral types, which are typically dominated by individual emission lines, features in second or higher order are easily identified in the figures because they appear at multiples of the wavelength of bright first-order lines.

 Fig. 1  Fig. 2

In spectra containing bright, relatively smooth continuum emission, including all of the white dwarfs and some of the cataclysmic variables, we have removed second and higher order flux using a bootstrapping algorithm. This technique first estimates the amount of contamination in higher orders from the first-order flux at the smallest wavelengths, subtracts this higher order flux from the spectrum, and then repeats the process using the newly cleaned spectral region. In this way, the algorithm works its way through all spectral orders and all wavelengths. Each subtraction step will add noise to the spectrum, and the cumulative noise added can be substantial at longer wavelengths, so this algorithm is only applied to spectra that have high S/N and for which order contamination is expected to be a problem. When order removal was performed on a source, we averaged the fluxed spectrum, rather than blocking the spectrum before fluxing. We indicate cases in which order removal has been performed in the individual figure captions for the spectra.

For most sources, we display both the individual spectra for each of the three *EUVE* spectrometers and a single, combined spectrum. The latter was formed by seaming together the spectra from the individual spectrometers (trimming away the overlap). The seam points were nominally at 170 and 350 Å, but for certain spectra, we moved a seam point to avoid placing a seam at the exact wavelength of a spectral feature. Some figures depart more drastically from the nominal display organization and will be described in their captions.

Where individual spectra from each spectrometer are shown, we have scaled the spectra so that each is shown over a wavelength range twice that of the next lower wavelength spectrometer. This means that, when no order removal has been applied, features in second and fourth order can easily be identified directly beneath their first-order counterparts in the lower wavelength spectrometers (although blends with first-order lines at the same wavelengths are also possible). See, for example, several lines in the LW spectrometer in Figure 42. As mentioned above, lines in second and higher order will have incorrect fluxes.

This scaling also keeps the plotted size of a resolution element on the page constant over all of the spectrometers in a figure. However, the actual resolution in angstroms increases by a factor of 2 from the SW to MW and MW to LW spectrometers. For example, when an unresolved emission line appears in two different spectrometers, the integrated flux over the line will be the same in both cases, but the line in the longer wavelength spectrometer will be twice as wide and half as high.

§2.2. *Selection and Organization of the Atlas*

We selected sources for inclusion in this atlas primarily by the quality of the *EUVE* spectrum and by their availability in the *EUVE* Public Archive. Our subjective quality criteria were applied by visually examining all public spectra of the appropriate spectral types and eliminating those that had extremely noisy spectra or no detection at all. We have included all selected sources that were public by 1996 June and a less complete selection of interesting sources that have become public up to 1997 February 1.

Because all of these data are taken from the public archive, the complete data sets are also available to any interested researchers by contacting the *EUVE* Public Archive. The authors intend to make all of the extracted spectra presented here available through the World Wide Web as well.

In Table 1 we list all of the sources included in this atlas. The positions are taken from the Second Source *EUVE* Catalog (Bowyer et al. 1996) and from An All-Sky Catalog of Faint EUV Sources (Lampton et al. 1997), except for Altair, HD 149499B, U Gem, and VV Pup, which are from SIMBAD. No *EUVE* names are given for these four sources since they were not detected during the all-sky survey and are not listed in the EUV source catalogs. The exposure times are the average of the SW, MW, and LW exposure times, which can differ slightly as described in the previous section. The observation dates represent the periods during which the observations took place, but the source may not have been continuously observed during the period. Where multiple dates are listed, we have summed the individual observations.

The subsequent sections of this paper contain the atlas, organized by spectral type and by subcategories within each type. However, white dwarfs have been ordered primarily by composition, given that they display extreme variations in photospheric abundances, and only secondarily are ordered by effective temperature. For each section, we present an overview of the EUV characteristics of sources of that type, followed by descriptions of the individual sources and the spectra themselves.

The O–M star spectra are displayed as a combined spectrum over the entire *EUVE* bandpass at the top, with individual SW, MW, and LW spectra below. For six bright, representative cases of emission-line sources, we show the individual spectra in more detail with identifications of prominent lines. The white dwarf spectra are shown as a combined spectrum at the top and one to three individual spectra below. As the white dwarf flux distribution is frequently concentrated in only part of the *EUVE* bandpass, we have omitted individual spectra possessing no significant flux. The source PG1159-035 was observed by *EUVE* and deemed important enough to deserve a description in the text, but the spectrum was undetected and is not shown. All of the cataclysmic variable spectra in the atlas also show flux concentrated in only one or two *EUVE* spectrometers and so are displayed in groups for easier comparison. For the source EX Hya, we have also shown a figure from the analysis by Hurwitz et al. (1997) to emphasize the time-variable nature of many of the spectra in this atlas, which is otherwise hidden by the use of aggregate spectra.

FOOTNOTES

[5] One frame equals 1.024 s.

[6] Primbsching is an algorithm that optimizes the use of a limited telemetry bandwidth among many different detectors with different background rates and, therefore, affects the live time of each, which is accounted for in the calculation of effective exposure time.

§3. O–A STARS

EUVE was not expected to detect early-type stars (O–A) both because they lack an active corona and and because they have large intervening hydrogen column densities as a result of their great distance. However, some predictions stated that the strong stellar winds of these stars, which produce the observed X-ray emission, would also emit in the EUV and that, therefore, *EUVE* would detect the earliest stars with low columns (MacFarland et al. 1991). In fact, many early-type stars were detected in the all-sky survey in the 100 Å Lexan/boron band. However, most, if not all, of the flux could be explained by an out of band UV leak in the Lexan/boron filter (λ > 2200 Å; McDonald et al. 1994).

Fortunately, a direction exists in which the intervening hydrogen column is less than 10^{18} cm^{-2} out to a distance farther than 200 pc (Welsh 1991). The constellation Canis Majoris lies in this direction and contains the two early B stars ϵ and β CMa, both of which were detected by their *photospheric* emission in the long-wavelength 600 Å tin bandpass. Indeed, ϵ CMa turned out to be the brightest EUV source in the sky (Vallerga, Vedder, & Welsh 1993).

We discuss the spectra of these two stars as they represent the early class with hot photospheres ($\approx$23,000 K) and EUV-emitting wind. *EUVE* also detected the A star Altair. Active binaries that contain a B star (e.g., Algol) and A-type stars with a white dwarf companion are discussed in subsequent sections.

ϵ *Canis Majoris*.—This B2 II star, 186 pc distant, is the brightest EUV source in the sky because of its intrinsic brightness and the fact that it is in a direction of very low interstellar hydrogen column density (9×10^{17} cm^{-2}). The radiation in both the H Lyman continuum and He I continuum (shortward of 504 Å) is found to be significantly greater than predicted by LTE and non-LTE model atmospheres, though the predicted strong absorption lines are present. In the ϵ CMa spectrum (Fig. 1), the S/N is high enough that all structure in the spectrum above 504 Å is real and not due to statistical variations. Absorption lines of highly ionized species in the hot wind of ϵ CMa are also observed. The strong He II Lyα emission at 304 Å is due to recombination of He^{++}, which is produced by the X-ray and EUV flux in the outer atmosphere and wind. The spectrum also shows strong O III 374 Å line emission produced by the Bowen fluorescence mechanism, an effect not previously observed in the spectra of hot stars. Detailed analysis of the spectrum can be found in Cassinelli et al. (1995). See Figure 1.

β *Canis Majoris*.—This is the only other early-type star (besides ϵ CMa) whose photospheric emission was detected by *EUVE*. A slightly higher interstellar neutral hydrogen column density (2×10^{18} cm^{-2}) results in a spectrum suppressed at the longer wavelengths compared to ϵ CMa. The photospheric continuum is inconsistent with current LTE and non-LTE stellar atmosphere models, though not as much so as ϵ CMa. Most of the same photospheric absorption lines are observed along with the absorption lines from the hot stellar wind. The lack of emission below 504 Å, especially at the He II recombination line at 304 Å, indicates a higher interstellar neutral helium column in this direction ($\approx 2 \times 10^{18}$ cm^{-2}), which implies the existence of a cloud of gas in this line of sight with ionized hydrogen and neutral helium. Detailed analysis of the spectrum can be found in Cassinelli et al. (1996). See Figure 2.

Altair (HD 187642).—This is an A7 V star, the only object in this class for which *EUVE* spectroscopic data exist. Its EUV spectrum reveals the unambiguous detection of the He II 303.78 Å line. Altair's atmosphere contains coronal material with temperatures of 10^5 K. There is no evidence for high-temperature material in the corona of Altair. See Figure 3.

 Fig. 3

§4. F–M STARS

Late-type stars, stars with spectral types F and later, constitute the largest group of EUV sources. The EUV emission from late-type stars consists of line and continuum emission formed over a broad range of temperatures (10^5 through 2×10^7 K or higher). The emission originates in the transition region and corona. One of the most interesting topics of modern astrophysics is *how the photospherically cool stars can have such high temperatures in their outer atmosphere*. The generally accepted theory posits that the heating processes originate in the convection zone where the combined effects of convection and rotation give rise to magnetic fields. The magnetic field energy dissipates in the upper atmosphere, which is in turn heated to high temperatures. The parameters of the convection zone and the stellar rotation rate are, therefore, the key elements that influence the emission. As a result of the large temperature range visible in the EUV, we can study many elements in different stages of ionization. For example, the He II lines can be used as a diagnostic in the low-temperature range, while the hottest line that can be detected is Fe XXIV. The fast-rotating dMe stars and RS CVn binaries show some of the highest temperatures (10^7 K), whereas the spectra of solar-type stars are dominated by lower coronal temperatures (a few 10^6 K).

In addition to presenting spectra of the brightest late-type stars in the standard format for this atlas in Figures 4–40, we also show selected sources in more detail, with identifications of the brightest spectral lines, in Figures 41–46. Procyon and α Cen AB illustrate the characteristics of the coolest EUV spectra; V711 Tau and σ^2 CrB represent the hottest spectra. Capella and ϵ Eri are intermediate cases.

§4.1. *F Star*

Procyon (HD 61421).—This is an F5 subgiant at a distance of 3.5 pc. The *EUVE* spectrum of Procyon is similar to that of α Cen in terms of the emission lines identified. The Procyon spectrum is typical for that of a relatively "cool" coronal source. This is best reflected by its emission-measure distribution, presented by Drake et al. (1995), which shows no evidence for coronal temperatures in excess of 3×10^6 K. Line ratios of Fe X (Foster, Edelstein, & Bowyer 1996) and Fe XIV (Schmitt et al. 1996a) indicate coronal electron densities in the range of $10^{9.2}$–$10^{9.5}$ cm^{-3}. Schrijver, van den Oord, & Mewe (1994) have argued that the nonzero continuum or pseudocontinuum flux present in the short wavelength spectrum is due to resonance scattering in the corona of Procyon. Their interpretation has been recently disputed by Schmitt, Drake, & Stern (1996b). See Figures 4 and 41.

§4.2. *RS CVn Binaries*

RS CVn binaries are, generally, detached systems with periods of 1–20 days that rotate quasi-synchronously with their orbital period. They typically comprise a late-type (G or K) subgiant or giant with a late-type main-sequence subgiant companion. They are chromospherically active, and their optical spectrum shows strong emission reversals in the Ca II H and K lines. The chromospheric and coronal activity of these systems arises from strong magnetic fields generated by the dynamo action. The catalog of chromospherically active binaries of Strassmeier et al. (1988) lists 104 RS CVn systems, 38 of which were detected during the *EUVE* all-sky survey in the Lexan/boron band (Mitrou et al. 1996). Several RS CVn binaries have been observed spectroscopically with *EUVE*. Here we present a range of spectra for the brightest of these systems.

VY Arietis (HD 17433 or GJ 113.1).—This is a single-line spectroscopic binary with an orbital period of 13.2 at a distance of 13 pc. It comprises an early K subgiant and a low-mass companion that has not been detected. Photometric observations indicate a rotation period of 17.4, which implies that the system is not in synchronous rotation (Bopp et al. 1989). The EUV spectrum of VY Ari is dominated by high-temperature lines of iron (Fe XVIII–XXIV) and the He II (304 Å) line is the strongest line in the spectrum. A weak short-wavelength continuum is also present. See Figure 5.

UX Arietis (HD 21242).—This is a double-line spectroscopic binary with spectral types of G5 V/KO IV and an orbital period of 6.438. The rotational period of the system is approximately equal to the orbital period. UX Ari is highly active. Strong Hα and Ca II H and K emission show that the cooler KO subgiant is the more active component of the binary. The system shows photometric variations in the *V* band, attributed to the rotation modulation of starspots on the surface; optical flares have recently been detected (Henry & Newsom 1996). UX Ari is the brightest RS CVn binary in the *EUVE* Lexan/boron band. The EUV spectrum is dominated by high-temperature lines of Fe XVIII–XXIV and He II. A strong continuum is also evident in the short-wavelength spectrum. A preliminary analysis of the DS data obtained during the spectroscopic observations indicates sinusoidal like variations in the Lexan/boron (Antonopoulou et al. 1997). However, these variations have no significant effect on the spectrum. See Figure 6.

V711 Tauri (HR 1099 or HD 22468).—This is a double-line RS CVn binary with spectral types of G5 IV/K1 IV and an orbital period of 2.84. It has been observed by *EUVE* on several occasions, as it is one of the primary wavelength calibration targets. This object is an extremely active RS CVn binary and has shown the most energetic stellar flare on an evolved magnetically active star, with a total energy of approximately 10^{38} ergs (Henry & Hall 1991). The system is known to exhibit rotational modulation in optical and UV wavelengths. Broadband *EUVE* observations (DS, 60–180 Å) have indicated a rotational modulation of about 40% with a minimum occurring at orbital phase $\phi = 0.5$ (Drake et al. 1994). The spectrum presented here is a composite of two spectra and is affected by rotational modulation as well as flare activity. High-ionization stages of Fe (Fe XV–Fe XXIV) and a very strong short-wavelength continuum are detected. This star and σ^2 CrB are the hottest coronae presented in this atlas. See Figures 7 and 45.

Capella (α Aurigae or HD 34029).—This is a double-line spectroscopic binary with G0 III/G5 III spectral type components. Although the spectrum is dominated by highly ionized iron (Fe XV–Fe XXIV), lower ionization stages are also present (e.g., Fe IX–Fe X) as well as the He II 256 Å and 304 Å lines. Plasma with a continuous distribution of temperatures from 10^5 to $10^{7.2}$ K is, therefore, present in the transition region/corona of Capella. A detailed study has been presented by Dupree et al. (1993). Ayres (1996) has suggested that the EUV spectrum of Capella is the blend of coronal emission from both components. See Figures 8 and 43.

σ Geminorum (HD 62044).—This is a single-line spectroscopic binary 59 pc distant. The visible primary has been classified as K1 III, whereas the invisible secondary is probably a main-sequence star of spectral type G or K. It has a photometric period of 19.41, which is very close to the orbital period of 19.6. The optical spectrum of the system exhibits strong emission in the Ca II H and K lines, whereas the Hα absorption is filled in by emission from the chromosphere. Coronal observations of σ Gem obtained with the medium- and low-energy detectors on *EXOSAT* show evidence for two temperature components: one at $\sim 5 \times 10^6$ K, which dominates the X-ray emission, and another at $\sim 40 \times 10^6$ K (Singh et al. 1987). The high-temperature coronal lines (Fe XVIII–XXIV) in the EUV spectrum of σ Gem show that the emission is dominated by temperatures of 10^7 K, somewhat higher than those indicated by the low-resolution *EXOSAT* results. Although the *EUVE* wavelength range contains no line diagnostic for temperatures higher than 2×10^7 K, the strong short-wavelength continuum indicates that higher temperatures exist in the corona of σ Gem. See Figure 9.

DH Leonis (HD 86590).—This is a triple, short-period RS CVn system with spectral types of K0, K7, and K5, an orbital period of 1.07, and distance of 33 pc. In an analysis of *EUVE* spectra of DH Leo, Stern & Drake (1995) report relative strengths of the density-sensitive Fe XXII 117 Å to 114 Å line ratio that are consistent with the low-density limit. See Figure 10.

ξ Ursae Majoris (HD 98230).—This is the B component of the visual binary ADS 8119. It is a single-line spectroscopic binary with an orbital period of 3.98. Dempsey et al. (1993) have presented *ROSAT* PSPC spectra for 44 RS CVn binaries of which ξ UMa has the lowest X-ray luminosity. A two-temperature fit with components at 2×10^7 K and 1×10^6 K seems to fit the PSPC data. The EUV spectrum of ξ UMa contains no evidence for such a high-temperature component. Emission lines of Fe XV–Fe XX and He II appear in the spectrum. The highest temperature implied by a weak Fe XX line is 8 $\times 10^6$ K. This object is the coolest of the RS CVn systems in the present sample. See Figure 11.

σ² Coronae Borealis (HD 146361).—This is a double-line spectroscopic binary system with an orbital period of $1^{\rm d}.1$. This is a very active binary consisting of two dwarfs with spectral types F6 and G0. Although the luminosity class of the two components is not typical of an RS CVn system, it displays many RS CVn–like characteristics and is therefore included in this class of objects. Based on *EUVE* all-sky survey data, Mathioudakis et al. (1995) recently examined the activity versus rotation relation in the EUV in a group of 73 nearby stars. The most active object in the sample was σ² CrB. Its EUV spectrum displays the highest ionization stages of Fe (up to Fe XXIV) and a strong short-wavelength continuum. This object and V711 Tau are the hottest coronae presented in this atlas. A preliminary analysis of the spectrum (Brown 1994) shows that it is a composite of flare and quiescent emission. See Figures 12 and 46.

AR Lacertae (HD 210334).—This is a double-line spectroscopic and eclipsing RS CVn binary of spectral type G2 IV/K0 IV with an orbital period of $1^{\rm d}.98$. The *EUVE* observation of AR Lac lasted approximately 3 days (effective exposure time of 90,000 s), or 1.5 orbital periods. The EUV spectrum of AR Lac is also dominated by lines of Fe XV–Fe XXIV, He II 304 Å, and a short-wavelength continuum. An initial analysis of the *EUVE* Deep Survey and spectroscopic data has been presented by Walter (1996). Using the Stern et al. (1995) technique for fitting the line-to-continuum ratio, Walter derives an iron abundance of 0.4 $M_\odot$ for the corona of AR Lac. The spectrum presented here is the composite spectrum including flare and quiescent data, both in and out of eclipse. See Figure 13.

λ Andromedae (HD 222107).—This is a G8 III–IV star and constitutes the primary of a single-line spectroscopic binary. It has a rotational period of ≈54 days, much longer than its $20^{\rm d}.5$ orbital period. Mewe & Schrijver (1986) analyzed *EXOSAT* observations of λ And and concluded that the data can be described by a two-temperature component at 8×10^6 K and 20×10^6 K. The low-temperature component is consistent with the detection of Fe XVIII–XXIII in the EUV spectrum. Given the high-temperature component present in the *EXOSAT* data, it is somewhat surprising that the Fe XXIV line is not present in the medium wavelength spectrum. However, λ And was detected in Al/Ti/C during the *EUVE* all-sky survey (Mitrou et al. 1996). See Figure 14.

II Pegasi (HD 224085).—This is a single-line spectroscopic binary of spectral type K2 IV–V with an orbital period of approximately $6^{\rm d}.72$. It is known for its very high activity rate in all regions of the electromagnetic spectrum. Despite several attempts in various spectral regions, its companion has yet to be detected. The coronal emission, therefore, originates from the K2 primary. Emission lines of Fe XX–Fe XXIII, He II 304 Å, and a short-wavelength continuum are apparent in the EUV spectrum. See Figure 15.

§4.3. *G Dwarfs*

κ Ceti (HD 20630).—This is a G5 dwarf at a distance of 9.6 pc. κ Ceti has been considered as a solar twin, but it is rotating faster than the Sun (a period of $9^{\rm d}.4$) and therefore is much more active. The strongest lines in the EUV spectrum of κ Ceti are Fe XV–XVI and He II. A weak Fe XVIII feature is also detectable at 93.92 Å, thus indicating the presence of material with temperatures up to 6×10^6 K. See Figure 16.

χ Orionis (HD 39587).—This is a G0 V star at a distance of 9.7 pc. It has a rotational period of $4^{\rm d}.7$ and therefore is more active than the Sun. It is, in fact, considered one of the younger solar twins (Haisch & Basri 1985). The EUV spectrum of χ Ori includes lines of Fe XV–XXIV as well as He II (303.78 Å), with the strongest emission at Fe XV and Fe XVI suggesting a significant coronal temperature component at log $T = 6.4$. The spectrum of χ Ori has been presented in detail by Haisch, Drake, & Schmitt (1994). See Figure 17.

α Centauri AB (HD 128620 or HD 128621).—This is a binary with spectral types G2 V and K1 V located at 1.3 pc. The spectral and activity parameters of the G2 V star make it very similar to the Sun. α Cen is the primary *EUVE* wavelength calibration target. Its spectrum contains ionization stages of Fe IX–XVI as well as lines of other species such as Ni XI (148.37 Å), Ni XII (152.15 Å), He II (256.30 Å), He II (303.78 Å), Mg IX (368.07 Å), Ne VII (465.22 Å), Si XII (499.41 Å), and O V (629.73 Å). The emission-measure distribution of α Cen has been presented by Mewe et al. (1995) and shows continuous emission from plasma below 5×10^6 K, with a broad peak at 3×10^6 K and a tail extended to 5×10^5 K. Several line ratios in the EUV spectra can be used for electron density diagnostics. For example, the line ratios of Fe X 175.26 Å/174.53 Å and 175.26 Å/174.24 Å imply densities of $10^{9.1}$ cm^{-3}; this value is consistent with the one determined from Fe XIV 219.12 Å/211.32 Å and 219.12 Å/211.08 Å (Keenan 1996; Foster et al. 1996). See Figures 18 and 42.

ξ Bootis (HD 131156).—This is a binary system comprising two dwarfs (G8 V + K4 V) located at a distance of 6.7 pc. The brightest component of the binary (G8 V) has a rotational period of $6^{\rm d}.2$. This is one of the few G dwarfs sufficiently bright in the extreme ultraviolet that high-quality spectra can be obtained. Lines of He II and Fe XV–Fe XX are the strongest in the EUV spectrum, which implies a maximum coronal temperature of 10^7 K. See Figure 19.

§4.4. *G Giants*

AY Ceti, also known as 39 Cet (HD 7672).—This is a single-line binary comprised of a G5 IIIe primary and a white dwarf secondary. AY Cet has a circular orbit with a period of 57 days, which is different from its photometric period of 78 days (Fekel & Eitter 1989). The presence of several high-ionization Fe lines in the short-wavelenth spectrum (e.g., Fe XVIII–Fe XXIII) suggests a temperature exceeding a few million K. Schrijver et al. (1995) present a thorough analysis of AY Cet, including a DEM curve. See Figure 20.

31 Comae Berenices (HD 111812).—This is a rapidly rotating single G0 giant with a projected rotational velocity of ∼ 80 km s^{-1} and an estimated rotational period of ≲5 days. In the H-R diagram, the object is located in the Hertzsprung gap. The EUV spectrum of 31 Com is dominated by high-temperature transitions of Fe XIX–XXIII, thus indicating a maximum coronal temperature of 10^7 K. An extensive analysis of 31 Com has been presented by Ayres & Brown (1994), Ayres (1996), and Dupree, Brickhouse, & Hanson (1996). See Figure 21.

§4.5. *Pre–Main-Sequence Star*

AB Doradus (HD 36705).—This is a K0–K2 IV–V star, located at approximately 20 pc. It is one of the fastest rotating late-type stars with a period of $0^{\rm d}.51$. This object is known to exhibit clouds of neutral hydrogen supported high above the photosphere in a manner similar to solar prominences. AB Dor is a pre–main-sequence star, the only object in this class for which high-quality EUV spectra exist. As a result of the very high activity, the EUV spectra are dominated by the highest ionization stages of Fe (Fe XV–XXIV), the He II lines, and a relatively strong short-wavelength continuum. A thorough analysis of the AB Dor spectra have been presented by Rucinski et al. (1995). See Figure 22.

§4.6. *K Giant and Subgiants*

β Ceti (HD 4128), a nearby red giant (K0 III, 16 pc).—This is a single active star and is a member of a class of coronally active "clump" giants (Ayres et al. 1994). See Figure 23.

Algol (β Persei or HD 19356).—This is the prototypical eclipsing binary system with a period of $2^{\rm d}.87$. It is comprised of a B8 V star and a K2 IV subgiant. The EUV spectrum of the system is typical of a high-temperature corona with the highest ionization stages of Fe (Fe XV– Fe XXIV) and the He II 304 Å line dominating the spectrum. The K2 IV corona is widely accepted as the source of the EUV emission from Algol. A short-wavelength continuum (80–120 Å) is a well-pronounced feature in the EUV spectrum. A thorough investigation of Algol has been presented by Stern et al. (1995). The relatively low line-to-continuum ratio indicates a [Fe/H] coronal abundance of 15%–40% of the solar photospheric abundance. See Figure 24.

§4.7. *K Dwarfs*

GJ 117.—This is a dK2 star at a distance of 8 pc. It is one of the few objects in its class with a strong Li I line in the optical spectrum. The high Li abundance (log $N_{\rm Li} = 2.50$) suggests that the object is very young, possibly less than a few million years, and comes from the Scorpio-Centaurus complex (Cayrel de Strobel & Cayrel 1989). The youth is consistent with its small rotational period of $6^{\rm d}.6$. The *EUVE* all-sky survey results give a low Lexan/boron to Al/Ti/C ratio for GJ 117, which indicates that it is a relatively soft coronal source (Mathioudakis et al. 1995). Emission lines of Fe XIV–XX are apparent in the EUV spectrum of the source where the strongest transitions are those of Fe XV (284.15 Å) and Fe XVI (335.41, 360.80 Å) formed at temperatures of ∼2×10^6 K. See Figure 25.

ϵ Eridani (GJ 144 or HR 1084).—This is a chromospherically active, K2 V, nearby dwarf with a distance of 3.29 pc. The most prominent spectral lines are He II at 256 Å and 304 Å, and Fe XVI at 336 Å and 360 Å. Schmitt et al. (1996c) report the detection of emission lines attributable to Fe in the ionization stages, Fe IX to Fe XXI, thus covering a rather large temperature range from less than 10^6 K to 10^7 K. They also have a density determination using line ratios of Fe XIII and Fe XIV resulting in coronal densities for ϵ Eri that are similar to solar active region densities. See Figures 26 and 44.

BF Lyncis (HD 80715).—This is a double-lined spectroscopic binary and one of the brighter members of BY Dra system with $m_v = 7.63$. The system consists of two nearly identical K2 V–K3 V dwarfs with an orbital period of $3^{\rm d}.8025$ and a distance of 29 pc. Stern & Drake (1996) showed that the Fe XXIII/XX feature is prominent, and other ionization stages from XV and XXII are also present, thus indicating a relatively hot corona. See Figure 27.

LQ Hydrae and VW Cephei.— LQ Hya (YZC 11 3651) is a young, single K dwarf (K0 Ve) with $m_v = 7.80$. The star displays extreme chromospheric activity as well as a large and variable spot distribution. See Figure 28. VW Cep is a W UMa–type contact binary and is also a component of a visual binary. See Figure 29. VW Cep is a system with known large flares. Both stars' EUV spectra feature Fe XX–XXIII as well as strong He II lines.

GJ 702AB (HD 165341).—This is a visual binary system comprising two K dwarfs (K0 V/K5 V) at a distance of 5 pc. The orbital period of the binary is 88 yr, whereas the brighter component has a rotational period of $19^{\rm d}.7$. The *EUVE* all-sky survey results have shown that it has a low Lexan/boron to Al/Ti/C ratio, thus indicating that it is a relatively soft coronal source (Mathioudakis et al. 1995). The strongest line in the EUV spectrum is He II 304 Å. The dominant Fe lines are Fe XV–XVI transitions indicating a maximum coronal temperature of ∼3×10^6 K. Several weak features in the 170–200 Å range are most likely attributed to Fe X–XIII. No lines could be positively identified in the short-wavelength spectrum. See Figure 30.

§4.8. *M Dwarfs*

YY Geminorum.—This is a late-type (M1 Ve) eclipsing spectroscopic binary system with flare activity. The He II line is prominent in the EUV spectrum of YY Gem as is Fe XX–XXIII. See Figure 31.

YZ Canis Minoris (GJ 285).—This is a nearby dMe star located at a distance of 6.2 pc. It has a rotational period of $2^{\rm d}.78$ and, therefore, is one of the most active flare stars. *EUVE* spectroscopic observations of YZ CMi were obtained in 1993 February 25–27 and 1994 December 21 and 24. The spectrum presented here is the composite of both data sets. However, note that the second data set was affected by a flare (Robinson et al. 1997). The EUV spectrum of the source is dominated by ionization stages of Fe XVI–Fe XXIII. See Figure 32.

AD Leonis (GJ 388).—This is an active dM4.5e flare star located at 4.9 pc. It has a rotational period of $2^{\rm d}.7$ and is one of the brightest EUV sources in its class. During the *EUVE* spectroscopic observations, which took place in 1993 March, two large flares occurred. The EUV spectrum presented here is a composite of the flare and quiescent states. It is dominated by Fe XV–XXIV and the He II lines. A weak, short-wavelength continuum is also apparent. A detailed analysis and interpretation of the data set has been presented by Cully et al. (1996) and Hawley et al. (1995). See Figure 33.

Proxima Centauri (α Cen C or V645 Cen).—This is the nearest known star to the Sun at a distance of 1.3 pc. This M5 V flare star is the faintest member of the α Cen triple star system. Prox Cen is a flare star that is chromospherically active with strong Mg II emission. This star is of great importance to magnetic dynamo theory because it is expected to have a fully convective envelope (Guinan & Morgan 1996). See Figure 34.

GJ 644 (Wolf 630).—This is a dwarf flare star. It is a member of a visual binary system with $m_v = 9.8$ and spectral type M4. The EUV spectrum indicates a strong He II line. See Figure 35.

AT Microscopii (Gl 799A or 799B).—This is a visual binary system in which both components are assigned the same spectral type, dM4.5e, and it probably forms a triple system with the dMe star AU Mic situated $1^{\circ}.3$ away. AT Mic is 8.8 pc distant. Monsignori Fossi et al. (1995a) studied the model of the coronal differential emission measure (DEM) as a function of temperature. The DEM shows a minimum at 10^6 K and a maximum at 10^7 K. The prominent lines in the AT Mic spectrum are due to highly ionized iron (Fe XVIII–Fe XXIII) formed at temperatures $6.7 \lesssim \log T \lesssim 7.1$. See Figure 36.

AU Microscopii (HD 197481).—This is a well-known flare star, at a distance of 8.8 pc. It is a rapidly rotating M2 Ve star and is suspected to be a spectroscopic binary with a small amplitude variability and a period of $4^{\rm d}.865$. The *EUVE* spectra were obtained in 1992 July and 1993 July, and a large-scale flare was observed during this time. The spectra here represent the composite of flare and the quiescent emission. In the short-wavelength range, Fe XXII (117.2 Å), Fe XXI (128.7 Å), and Fe XXIII (132.86 Å) have been observed, while the prominent lines in the medium-wavelength spectrum are high-temperature Fe XXIV (192.02 Å) as well as low-temperature He II (303.78 Å) chromospheric lines. See Figure 37. A detailed study of temperature, density, and emission measure of AU Mic is shown by Monsignori Fossi et al. (1996).

FK Aquarii.—This is a BY Draconis star with a pair of dM2e stars and a photometric period of $4^{d}.08$. It lies at a distance of 7.7 pc. Spectral differences in the "quiescent" and "active" states of the EUV spectrum suggest possible differences in the plasma density structure, as Stern & Drake (1996) show. See Figure 38.

EV Lacertae (GJ 873).—This is an active dM4.5e flare. This star is known for producing extreme flares at both optical and X-ray wavelengths (Ambruster et al. 1995). See Figure 39.

EQ Pegasi (Gl 896AB).—This is a visual binary comprised of two M dwarfs with spectral types dM4e and dM5e. The separation of the binary is $3''.7$ and, therefore, cannot be resolved by *EUVE*. The coronal emission is, however, dominated by Gl 896A, the brighter component in the binary. As is the case with the vast majority of flare stars, the EUV spectrum of the source is dominated by Fe XV–Fe XXIV lines and He II 256 Å, He II 304 Å. During the spectroscopic observations, two flares with a duration of approximately 15 hr were detected. A detailed analysis of the 1993 August 29–30 observation has been presented by Monsignori Fossi et al. (1995b). See Figure 40.

For six bright, representative cases of emission-line sources, we show the individual spectra in more detail with identifications of prominent lines. See Figures 41, 42, 43, 44, 45, and 46.

§5. WHITE DWARFS

Single white dwarfs (WDs) are the second most numerous category of EUV sources discovered to date, comprising nearly a third of the cataloged objects. They are extremely luminous EUV emitters, having been detected at distances of up to 400 pc. The copious EUV flux produced by white dwarfs is simply thermal emission from their photospheres. Shipman (1979) recognized that for hot white dwarfs with essentially pure hydrogen atmospheres, the opacity at short EUV wavelengths is very small, which allows radiation to escape from very hot, deep layers of the atmosphere. At 100 Å, for example, the flux of a 50,000 K pure H white dwarf exceeds that from a blackbody of the same effective temperature by more than 6 orders of magnitude.

In addition to being fascinating objects in their own right, white dwarfs have long been appreciated as laboratories in which we can study the physics of matter under conditions not achievable in terrestrial laboratories. (A recent review of the physics of white dwarfs may be found in Koester & Chanmugam 1990.) Their extreme compactness, with about half the mass of the Sun occupying a volume comparable to that of Earth, results in very interesting interior physics, which will not be discussed here. Their observable properties are largely determined by their surface gravity, which is typically 4 orders of magnitude stronger than in the Sun. Schatzman (1949, 1958) pointed out that such high gravity should result in white dwarf atmospheres consisting almost purely of the lightest dominant atmospheric constituent because of rapid gravitational settling of the heavier elements, thereby explaining the observational fact that most white dwarfs have either nearly pure hydrogen or helium atmospheres. White dwarfs in which hydrogen is the dominant constituent are referred to as DA's, based on the nondetectability in optical spectra of elements other than hydrogen. Those with mostly He atmospheres, which are hot enough to be detected in the EUV, are designated DO white dwarfs. Another category of degenerate stars, which are usually grouped with white dwarfs but can be regarded as pre–white dwarfs because they are still contracting to the white dwarf sequence, are the PG 1159 (GW Vir) objects. These objects have atmospheres mostly consisting of He and C (Werner, Heber, & Hunger 1991).

In addition to the gravitational settling that works to produce monoelemental atmospheres, the hotter white dwarfs have extremely intense radiation fields. The effect of the strong radiative fluxes is to levitate selectively some elements, even against the extremely strong gravitational fields present (Vauclair, Vauclair, & Greenstein 1979; Vauclair 1989). The greatest effects on the emergent flux resulting from trace heavy elements are seen in the EUV. Therefore, it was the initial *EUVE* spectra of hot DA white dwarfs that finally confirmed that elements other than helium were the long-sought source of excess opacity detected photometrically in hot DA's. Detailed analysis of the EUV spectra now enables us to study the interplay between gravitational settling and radiative levitation under a wide range of physical conditions in white dwarfs.

Because the white dwarfs are intrinsically luminous continuum sources, they also provide a means of characterizing the state of the interstellar matter along the lines of sight to the white dwarfs. When observable, the flux longward of 504 Å can be used to infer the neutral hydrogen column density. The 504 Å edge gives a direct measurement of the He I column density for WDs with low column densities, while the 206 Å He I resonance feature serves the same function for objects with higher column densities. The 228 Å edge allows the determination of the He II column density. Thus, for white dwarfs that are not complicated by uncertain trace element abundances and that have measurable flux longward of 228 Å, the EUV spectra may be used to determine H I, He I, and He II abundances, thereby fully characterizing the ionization balance in the part of the ISM that lies along that line of sight.

§5.1. *DA White Dwarfs*

The DA white dwarfs may generally be grouped into three categories. With only a couple of exceptions, those cooler than about 50,000 K have pure H atmospheres, with heavy elements being undetectable even in EUV spectra. Representative objects in this category include HZ 43, GD 71, and GD 153. Above about 50,000 K, radiative support produces detectable amounts of heavy elements in nearly all DA's. The general trend is for abundances to increase with increasing temperature and decreasing gravity. In principle, a continuous range of trace element abundances is expected to be observed. In fact, though, presumably fortuitously, the hot DA white dwarfs with detectable amounts of trace heavy elements that have been observed spectroscopically tend to be found in two groups. The first group, typified by G191-B2B and Feige 24, consists of stars with quite high trace element abundances that are readily identifiable by fluxes that peak in the MW spectrometer bandpass, while very little flux is in the SW spectrometer.

The second group has moderate trace element abundances and is typified by objects such as PG 1123+189 and PG 1234+482. These stars are much less heavily absorbed and have appreciable SW flux with discrete features detectable in well-exposed spectra.

§5.1.1. *Pure Hydrogen DA White Dwarfs*

GD 2 (WD 0004+330).—This star, with an effective temperature of 49,360 K and log g = 7.63 (Finley, Koester, & Basri 1997), lies in the region where the transition occurs from pure H atmospheres to atmospheres with significant abundances of trace elements. Therefore, we wish to determine whether trace heavy elements are detectable in the EUV spectrum of GD 2. Unfortunately, this star is quite faint, so that discrete features cannot be seen in the spectrum. It also has a high interstellar H I column (4.8 × 10^{19} cm^{-2} per Diamond, Jewell, & Ponman 1995), the consequence of which is that no flux is detected longward of about 125 Å. Therefore, the overall shape of the spectrum cannot be used to determine trace element abundances. However, with good optical limits on the effective temperature and gravity, the overall flux level in the EUV spectrum may be used to jointly constrain trace element abundances and the interstellar column. See Figure 47.

 Fig. 47

GD 659 (WD 0050-332).—This star definitely lies within pure H temperature range, with T_{eff} = 35,820 K (Finley et al. 1997). It has a moderate column, such that some flux is detected even in the short-wavelength end of the LW spectrometer. The spectrum includes the interstellar He I λ206 features as well as a significant interstellar He II λ228 edge. Holberg et al. (1995) fitted the EUV spectrum, including these features, to determine the interstellar H I, He I, and He II columns. See Figure 48.

 Fig. 48

HD 15638B (WD 0226-615).—This star, the white dwarf companion to HD 15638A, was detected as an EUV source by the WFC and identified as a white dwarf by Landsman, Simon, & Bergeron (1993), who determined that the effective temperature was between 40,500 and 52,000 K, while log g was in the range of 7.35–8.3. Landsman et al. also determined the spectral type of the primary to be F6 V. Barstow et al. (1994a) determined the white dwarf parameters using *IUE* and *Voyager* data and the photometric distance for the F companion, obtaining T_{eff} = 53,500 K and log g = 8.2. For these values, Barstow et al. noted that the EUV photometry required the presence of trace absorbers. However, with a somewhat cooler effective temperature, the observed EUV spectrum is consistent with a pure H atmosphere. See Figure 49.

 Fig. 49

2RE J0515+324.—This is a DA white dwarf companion to an F4 V star, HD 33959C, and was identified as the optical counterpart on the basis of *IUE* observations by Hodgkin et al. (1993). No analysis of the EUV spectrum has been published as yet. See Figure 50.

 Fig. 50

GD 71 (WD 0549+158).—This is a 32,750 K (Finley et al. 1997) pure H DA with very low interstellar columns. Significant flux is seen in all three *EUVE* spectrometer channels. The EUV spectrum was extensively analyzed by Dupuis et al. (1995), who determined the H I and He I columns and obtained an upper limit for the He II column. Barstow, Holberg, & Koester (1994b) had earlier compared the EUV spectrum to stratified models, in which a layer of hydrogen overlies a layer of helium with which it is in diffusive equilibrium, in order to determine whether evidence of helium existed. They found that the observed spectrum was indistinguishable from that of a pure hydrogen atmosphere. See Figure 51.

 Fig. 51

Sirius B.—This star is historically important as the third white dwarf discovered, and the first to have its mass determined Boss (1910), thereby demonstrating the degenerate nature of white dwarfs. Sirius B is near the cool end of the EUV-detectable DA range and is reasonably bright only because it is a mere 2.66 pc distant (Gliese & Jahreiss 1988). In this temperature range (approximately 25,000 K), the intrinsic stellar flux is the result of the combined effects of the steep Wien tail of the Planck function and the decreasing opacity of neutral hydrogen toward shorter wavelengths. The result is that the flux drops from below the Lyman edge to a minimum around 350 Å and then rises to a narrow peak around 150 Å. The 350 Å flux is only about 0.5% of the 150 Å flux (in photons cm^{-2} s^{-1} $Å^{-1}$) and, thus, is essentially undetectable with *EUVE* because of the contribution of the flux peak in higher spectral orders. The intrinsic flux is as high at 800 Å as it is at the 150 Å peak. Hence, if the H I column to the Sirius system is as low as 3.4 × 10^{17} cm^{-2}, as estimated by Bertin et al. (1995) based on D I column measurements, detectable flux could be present longward of about 600 Å along with about equal contributions to the count spectrum from third- and fourth-order flux. Detection of >600 Å flux in the *EUVE* spectrum could provide a valuable confirmation of that column estimate. However, fitting the EUV spectrum to obtain columns requires an accurate normalization of the model flux (via optical or far-UV photometry or spectrophotometry), which is difficult given that Sirius B lies only a few arcseconds distant from the brightest star in the sky. Fitting the SW portion of the spectrum could provide the most accurate effective temperature to date for Sirius B, and then the MW and LW spectra could provide the interstellar columns, given a sufficiently accurate calibration of the SW spectrometer, and all orders of the LW spectrometer. See Figure 52.

 Fig. 52

2RE J0715-702.—This is likely to be a pure H DA, given that T_{eff} = 43,870 K and log g = 8.048 (Finley et al. 1997). Flux is present throughout the SW spectrometer channel, with adequate S/N to search for discrete absorption features. The MW flux is essentially zero longward of about 200 Å, due to a relatively high H I column of log $N_{H\,I}$ = 19.6 (Wolff, Jordan, & Koester 1996), making explicit determinations of the interstellar He I and He II column densities impossible. See Figure 53.

 Fig. 53

2RE J1032+532.—This lies in the range of effective temperature and gravity in which the transition occurs from pure H to metal-rich, with T_{eff} = 46,900 and log g = 7.77 (Finley et al. 1997). The *ROSAT* PSPC and WFC photometry for this star were analyzed by Wolff et al. (1996) who found slight evidence for trace heavy elements and determined the H I column to be about 1×10^{19} cm^{-2}. Flux is present in both the SW and MW spectrometers, but the star is not detected longward of about 400 Å in the LW spectrometer. This spectrum includes an interstellar He II λ228 edge and a very nice example of the interstellar He I resonance feature at 206 Å. See Figure 54.

 Fig. 54

LB 1919 (2RE J1059+512).—This is a difficult object to analyze. Its unusual Balmer line profiles (Finley et al. 1997) render problematical the independent, accurate temperature determination required for an abundance estimate. The overall shape of the spectrum, in which the flux peaks in the SW spectrometer, does indicate that the abundances of any trace elements that may be present are certainly much lower than for DA's such as Feige 24 and G191-B2B. Detectable flux is present shortward of about 300 Å; thus, analysis of the spectrum can, in principle, yield the WD properties and ISM columns. See Figure 55.

 Fig. 55

PG 1057+719.—This is cool enough at 41,460 K (Finley et al. 1997) that it is not expected to have any heavy elements in its atmosphere. The ISM column density is high enough that there is almost no flux around the 228 Å He II edge and poor S/N is obtained in the vicinity of the He I 206 Å resonance feature. Analysis of the spectrum will therefore provide a measurement of the H I ISM column, but not a full characterization of the ISM along the line of sight. See Figure 56.

 Fig. 56

GD 153 (WD 1254+223).—This is a pure H white dwarf with a low column, providing usable flux in all three *EUVE* spectrometer bandpasses. The EUV spectrum has been analyzed by Dupuis et al. (1995), who confirmed that the WD atmosphere is pure H and determined the ISM H I and He I columns and also obtained an upper limit to the He II column. The apparent broad absorption feature between 200 and 250 Å that is most visible in the spectra of GD 153 and HZ 43 is not intrinsic to the stars. Rather, it is a consequence of the ±10% relative accuracy of the calibration effective area of the instrument as a function of wavelength. See Figure 57.

 Fig. 57

HZ 43.—This is the first extrasolar EUV source discovered (Durisen, Savedoff, & Van Horn 1976; Margon et al. 1976). It is the brightest EUV source, with a very low column, providing an excellent EUV spectrum in all three *EUVE* spectrometer bandpasses. The *EUVE* spectra have been analyzed more than once. Dupuis et al. (1995) obtained the interstellar columns, and Barstow, Holberg, & Koester (1995) obtained a stringent upper limit to the helium abundance in HZ 43. See Figure 58.

 Fig. 58

CD -38 10980 (WD 1620-391).—This has nearly the same effective temperature as Sirius B (25,280 K per Finley et al. 1997) but is much fainter given its distance of about 15 pc. Based on the analysis of Finley et al. (1993), at that effective temperature, log $N_{H\ I}$ = 18.8, consistent with the absence of detectable flux longward of about 220 Å. That column is somewhat high given its distance of only 13 pc (Vauclair et al. 1997) but is consistent with the interstellar columns of C, N, O, and S determined by Holberg, Bruhweiler, & Andersen (1995) based on *IUE* observations. The circumstellar material reported by Holberg et al. (1995) in the line of sight to CD -38 10980 (predominantly C II and Si III) is not expected to have a detectable effect on the EUV spectrum. See Figure 59.

 Fig. 59

2RE J1746-703 (WD 1740-706).—This is a massive DA, with T_{eff} = 46,420 K, log g = 8.97, and M = 1.21 $M_\odot$ (Finley et al. 1997). As such, it would be expected to have a pure hydrogen atmosphere. The EUV photometry is consistent with pure H, while the overall appearance of the EUV spectrum is indicative of an atmosphere that is pure H or contains only small amounts of trace absorbers. The EUV spectrum was analyzed in detail by Dupuis & Vennes (1997), who derived an upper limit to the He abundance of He/H 1.3×10^{-4}. See Figure 60.

 Fig. 60

Lanning 18 (WD 1845+019).—This is somewhat hotter than CD -38 10980 (29,460 K per Finley et al. 1997) and has a somewhat lower column of log $N_{H\ I}$ = 18.35 ± 0.3 (obtained by applying that effective temperature to the analysis of Finley et al. (1993). The combination of higher effective temperature and lower column results in detectable flux being present out to about 280 Å. However, the low column and faintness of the source preclude obtaining meaningful constraints on the He I and He II columns using the EUV spectrum. See Figure 61.

 Fig. 61

2RE J2009-602.—This is most likely a pure H DA. Wolff et al. (1996) analyzed the *ROSAT* PSPC and WFC photometry, obtaining T_{eff} = 42,900 and log $N_{H\ I}$ = 19.39, independent of an optical temperature determination. Those results are consistent with the EUV spectrum. Additionally, the presence of flux out to about 250 Å, combined with the relatively high column, should allow independent determinations of the He I and He II column densities. See Figure 62.

 Fig. 62

2RE J2024-422 (MCT 2020-4234).—This has precisely the same effective temperature as Lanning 18 but is 1.7 mag fainter at visible wavelengths. As a result, the spectrum (with only a 34 ks exposure) is too faint to be useful for constraining the properties of the star or the interstellar column densities. See Figure 63.

 Fig. 63

IK Pegasi (HR 8210).—This is a binary consisting of an A8m and a DA. Confirmation of the presence of the white dwarf based on *IUE* spectroscopy was obtained independently by Wonnacott, Kellet, & Stickland (1993) and also by Landsman et al. (1993). Landsman et al. determined that T_{eff} = 35,500 K and log g = 9.0. The analysis of Wonnacott et al. (1993) also indicated that this is a high-mass white dwarf. Barstow et al. (1994a) reported that those values are entirely consistent with the EUV photometry for this star. The latter also estimated that $N_{H\ I} = 7 \times 10^{18}$ cm^{-2}, consistent with the presence of EUV flux out to nearly 400 Å. See Figure 64.

 Fig. 64

2RE J2156-543.—This is cool enough at 44,330 K (Finley et al. 1997) that it is most likely a pure H DA, which is corroborated by the EUV spectrum. Usable flux is present out to about 350 Å, and the star is bright enough in the 200–250 Å range to obtain measurements of the He I and He II columns. See Figure 65.

 Fig. 65

2RE J2324-544 (WD 2321-549).—This has T_{eff} = 44,960 and log g = 7.94 per Finley et al. (1997), and 44,800 and 8.00 per Vennes et al. (1996c). Vennes et al. also analyzed the EUV photometry, which appeared to indicate that trace heavy elements were present in this star. However, that result depends on the *V* magnitude they derived from the *HST* Guide Star Catalog magnitude, which had an estimated error of 0.40 mag. The EUV spectrum will need to be analyzed using an accurate scale factor. Assuming a somewhat fainter *V* magnitude results in the EUV photometry and spectroscopy being consistent with pure H. See Figure 66.

 Fig. 66

§5.1.2. *Metal-rich DA White Dwarfs*

The heavy element opacity in metal-rich DA stars is in the form of line blanketing and overlapping bound-free absorption edges that begin around 300 Å, increase markedly around 260 Å, and progressively become stronger toward shorter wavelengths. The trace element opacity can be so great that typical metal-rich DA white dwarfs can have fluxes at 100 Å that are 4 orders of magnitude less than that of a pure H model that matches the observed flux longward of 300 Å.

G191-B2B.—This is the "prototypical" metal-rich DA white dwarf. It was known already to have among the highest trace element abundances detected in DA's based on *EXOSAT* photometry (Paerels & Heise 1989). Inclusion of EUV and soft X-ray photometry from *ROSAT* showed that the trace absorber was not He, whether uniformly mixed or in a stratified configuration (Barstow et al. 1993). The first EUV spectrum of G191-B2B, obtained with a rocket-borne spectrometer, showed that trace heavy elements other than He were present but did not allow a firm identification of the constituents (Wilkinson, Green & Cash 1992). Because it is one of the brightest EUV sources, a calibration target, and extremely interesting in its own right, a wealth of spectroscopic data for G191-B2B has been obtained with *EUVE*. The spectrum is so rich it has proved difficult to fit, whether with LTE or NLTE models. Preliminary results have been given by Koester (1995) and Barstow et al. (1995b), and a better fit was presented by Lanz et al. (1996). Additional help in determining the trace element abundances has been provided by individual element abundance measurements obtained by observations in other wavelength ranges, particularly the far-ultraviolet (FUV). A voluminous literature exists on this topic; we mention only one of the earliest (Bruhweiler & Kondo 1981) and one of the latest (Vennes et al. 1996b). See Figure 67.

 Fig. 67

Feige 24, *MCT 0455-2812*, *2RE J0623-374*, *2RE J2214-491*, and *MCT 2331-431*.—The general appearance of the EUV spectra of these other metal-rich DA's is quite similar to that of G191-B2B. All have moderate interstellar absorption with some LW flux detected. 2RE J0623-374, 2RE J2214-491, and MCT 2331-431 have somewhat higher columns than the others, with no flux detected at the He I λ504 edge. The stars in this group do differ in their temperatures, gravities, and elemental abundances. When individual element abundances are obtained for these objects, differential abundance comparisons will be helpful in the theoretical understanding of the factors that determine those abundances. See Figures 68, 69, 70, 71, and 72.

 Fig. 68  Fig. 69  Fig. 70
 Fig. 71  Fig. 72

HD 223816B (WD 2350-706).—This was estimated by Barstow et al. (1994a) to have an effective temperature of about 60,000 K if log *g* were assumed to be 7.5, based on the photometric distance for a its G0 V companion and on *IUE* and *Voyager* spectra. The temperatures and gravities are similar to those for G191-B2B. Additionally, the EUV spectrum for HD 223816B, like that of the other metal-rich DA, is qualitatively similar to that for G191-B2B. The relatively higher SW flux suggests that the metal abundances are somewhat lower, though, than for G191-B2B. See Figure 73.

 Fig. 73

§5.1.3. *Intermediate-Metallicity DA White Dwarfs*

While we expect a continuously varying distribution of trace element abundances among hot DA's, this small sample of stars that definitely have trace elements present is distinctly (and most probably by chance) clumped. In addition to the metal-rich DA's discussed above, a nearly equal number of "intermediate-metallicity" DA's exist that have metal abundances at least an order of magnitude lower. The two groups are readily differentiated by a visual inspection of the EUV spectra. Metal-rich objects, typified by G191-B2B, have very little flux in the *EUVE* SW spectrometer relative to that in the MW. All the intermediate-metallicity DA's, on the other hand, have equivalent flux levels in both the SW and MW spectrometers. Lower abundances result in much brighter spectra that have less heavily overlapping features from the different elements present. Both factors make the intermediate-metallicity DA's promising subjects for the direct identification of trace heavy elements in the EUV spectra.

2RE J0029-632.—This is not a candidate for detailed trace element abundance determinations. Given its faintness and high column density, at best one may estimate a metallicity based on the reduction of the observed flux relative to that predicted for pure H composition at the optically determined effective temperature. See Figure 74.

 Fig. 74

PG 1234+482.—More progress has been made in studying this object. Jordan et al. (1994) identified Fe as definitely being present in this star, while only upper limits were obtainable for other elements such as Ni, Ca, C, N, O, and Si. See Figure 75.

 Fig. 75

PHL 1043 (or WD 0131-163), *PG 1123*+189, and *GD 246*.—These objects display similar features to those mentioned above and have reasonably well-exposed spectra. Hence, analyses of the EUV spectra for stars in this group should yield useful information on the differential effects of temperature and gravity on trace element abundances. See Figures 76, 77, and 78.

 Fig. 76  Fig. 77  Fig. 78

§5.2. *Helium-rich White Dwarfs*

Overall, roughly 10% of white dwarfs have He-dominated atmospheres. However, a much smaller fraction is detectable in the EUV. Photospheric He absorbs strongly shortward of the He II λ228 absorption edge in the hotter objects, while somewhat cooler stars have very little flux shortward of the He I λ504 edge. The intrinsic stellar flux for such objects may be detected only if the interstellar column is sufficiently low. The situation is potentially more favorable for very hot He degenerates ($T_{\rm eff}$ > 100,000 K) that ionize He II sufficiently strongly that significant flux may be present even shortward of 228 Å.

2RE J0503-285 (MCT 0501-2858).—This is a DO white dwarf that differs significantly from HD 149499B and other typical cool DOs as described in Wesemael, Green, & Liebert (1985). It has in its optical spectrum the C IV/He II blend around 4670 Å (Barstow et al. 1994c) that was first discovered in the prototype of the PG 1159 class of hot, He-rich white dwarfs, PG 1159-035 (McGraw et al. 1979; Green & Liebert 1979). However, while the effective temperature of 2RE J0503-285 is around 70,000 K (Barstow et al. 1994c), the previously discovered members of the PG 1159 class have been much hotter (100,000–170,000 K; Dreizler, Werner, & Heber 1995). The EUV photometry showed that trace absorbers other than H, He, and C were present (Barstow et al. 1994c), while *IUE* spectroscopy has resulted in the detection of C, N, O, and Si, but not Fe or Ni, in distinction to the hot H-rich DA's in this temperature range. This star is sufficiently complex that a satisfactory fit to the EUV spectrum has not yet been achieved. See Figure 79.

 Fig. 79

HD 149499B.—This is a typical DO white dwarf that was fortuitously detected in the EUV because it is just hot enough and close enough, with only a moderately high interstellar column, so that it is detected only within the He II Lyman series. The flux actually peaks around 275 Å, while essentially none is detected below the 243 Å He II line. Above the 304 Å line, the flux disappears by about 380 Å because of ISM absorption. Napiwotzki et al. (1995) analyzed the EUV and FUV spectra for this star, obtaining consistent results from fitting both the He II Lyman and Balmer series: $T_{\rm eff}$ ~ 50,000 K, log *g* ~ 7.9, He/H > 10, and an interstellar H I column density of 7 × 10^{18}. They did not report the detection of any other trace elements in that preliminary analysis. See Figure 80.

 Fig. 80

PG 1159-035.—This star, the prototype for the PG 1159 objects, was observed for about 40,000 s with *EUVE* in the hope that the flux around 100 Å would be measurable. Unfortunately, the star was just too faint to obtain a usable spectrum.

PG 1520+525.—This is somewhat brighter then PG 1159-035 and was observed for 155,000 s. The spectrum, though somewhat weak and noisy, was sufficient to place the effective temperature around 150,000 K, based on the observed strength of the O V absorption edge at 120 Å (Werner et al. 1996). See Figure 81.

 Fig. 81

§5.3. *Unusual White Dwarfs*

GD 50.—This is the most massive, nonmagnetic, single DA white dwarf known (Bergeron et al. 1991). It is also unique among DA white dwarfs in showing He in the EUV spectrum (Vennes, Bowyer, & Dupuis 1996a). The photospheric features visible in the EUV spectrum are the He II Lyman line series, and little flux is detected below the He II 228 Å edge. See Figure 82.

 Fig. 82

V471 Tauri.—This has properties that differ from those of typical DA's because it is in a close binary system. Recent analyses by Dupuis et al. (1997) confirm that the spectral peculiarities are due to material accreted onto the white dwarf from the stellar wind of the K0 V companion, that is concentrated by the white dwarf's magnetic field onto "spots" on its surface. The time-averaged spectrum displayed in the figure does not properly represent the true nature of this star, though. The spectrum actually varies with rotational phase because of varying trace element abundances over the face of the star. See Figure 83.

 Fig. 83

2RE J1016-052.—This is one of only two white dwarfs classified as DAO that have been detected in the EUV. Optical and FUV observations have detected He II λ4686 and λ1640 features, as well as the C IV λ1550 doublet (Tweedy et al. 1993; Thorstensen, Vennes, & Bowyer 1996). This is a post–common-envelope object consisting of the white dwarf and a low-mass M companion. The spectrum shows only continuum emission that is detectable only below about 170 Å owing to a column density that is in excess of 10^{19} cm^{-2}. While the analysis of the EUV spectrum is less straightforward than it would be if observable flux were present longward of 228 Å, an apparent inconsistency exists between the observed EUV flux and that which would be expected based on the optically determined temperature and He abundance. Analyses of the EUV data are now underway to resolve this discrepancy (Vennes et al. 1997). See Figure 84.

 Fig. 84

H1504+65.—This is perhaps best classified as a "pre–PG 1159" object. It is extremely hot, around 170,000 K, with a C- and O-dominated atmosphere essentially devoid of He, while the features observed in the FUV and optical are from C IV and O VI (Werner 1991; Nousek et al. 1993). Because of its high interstellar column density, flux is detectable only shortward of about 150 Å. However, below that limit, the spectrum has good S/N and has many strong features that are mostly due to O VI. However, additional sources of opacity are present that are not accounted for in pure C/O models (Barstow et al.

1995a). See Figure 85.

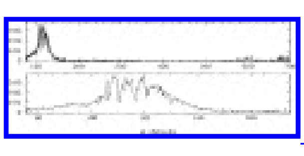

Fig. 85

GD 394.—This is the coolest DA found to have significant trace element abundances. Bruhweiler & Kondo (1983) first detected Si III and Si IV in this star. Its effective temperature from Balmer line fitting is almost 40,000 K (Bergeron, Saffer, & Liebert 1992; Finley et al. 1997), but the temperature obtained from fitting the Lyα profile was 36,000 K (Holberg, Wesemael, & Basile 1986). The FUV continuum is depressed, such that the temperature based on the FUV/optical flux ratio was only 37,000 K (Finley, Basri, & Bowyer 1990). The EUV spectrum was recently analyzed by Barstow et al. (1996). They found that including Si with the abundance determined from FUV observations did not provide the observed EUV opacity. They did, however, obtain a (nonunique) fit to the EUV spectrum by adding C, N, and O at abundances just below those at which features that were not detected in the EUV would become visible. Certainly, more work is required to determine the trace element abundances in this object and produce a self-consistent fit to the full spectrum and to resolve the puzzle of how such a cool DA can have such high trace element abundances. See Figure 86.

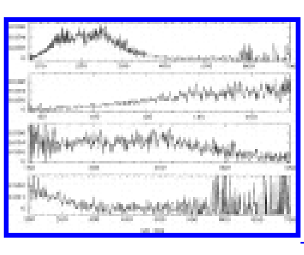

Fig. 86

§6. CATACLYSMIC VARIABLES

The *EUVE* satellite represents a new and exciting realm for research in cataclysmic variables. To date, *EUVE* has performed 25 pointed (spectra and imaging) observations of CVs, of which we display 15 with high S/N. *EUVE* provided the first opportunity to obtain spectral resolution of ~1 Å in the EUV bandpass (70–760 Å). *EUVE* has also supplied us with unprecedented photometric information, which will be reviewed elsewhere.

Cataclysmic variables come in a few varieties: novae, nova-likes, dwarf novae (DNs), AM Herculis stars, and DQ Herculis stars. Here we review *EUVE* spectroscopic observations of DN, AM Her, and DQ Her stars. All have white dwarf primaries: those in AM Her stars possess a very strong magnetic field (10–230 MG), and DQ Her primaries have moderate fields (1–10 MG). The secondary stars are thought to be normal main-sequence dwarfs.

In the AM Her–type CVs, accreting material is magnetically funneled directly onto the white dwarf surface in a tightly confined spot of approximately 1000 km in the EUV spectral range. This accretion spot is the major source of EUV photons in the AM Her stars. The much lower or null magnetic fields in the dwarf novae primaries allow the accreted material to form a roughly flat disk that may extend all the way to the white dwarf surface. This disk–primary star interface, called the boundary layer, is thought to be the source of much of the high-energy emission during a dwarf novae outburst. The DQ Her stars are approximately in between these two extremes, being thought to contain a partial (annulus) disk and a broader curtain-like accretion region. The entire field has been recently reviewed by Warner (1995).

§6.1. *Dwarf Novae at Outburst*

Dwarf novae (DNs) consist of a semidetached binary containing a white dwarf primary and a roughly normal lower main-sequence (K–M) secondary. The secondary loses material via Roche lobe overflow, and this material forms an accretion disk around the primary star that can extend all the way to the WD surface (i.e., the boundary layer). These stars show semiperiodic outbursts of 2–5 mag that are thought to occur when material stored in the accretion disk is suddenly accreted onto the WD surface owing to angular momentum loss caused by thermally unstable viscous heating (see Cannizzo, Shafter, & Wheeler 1988). DNs with orbital periods in the range of 2–3 hr are uncommon, and this interval has been termed the "period gap."

During minimum light DNs are not large producers of high-energy radiation, and their generally moderate to large distances ($\gtrsim$100 pc) mean that the ISM absorbs large amounts of the EUV photons, making DN weak EUV sources while at minimum light. However, when they undergo an outburst, the boundary layer becomes quickly heated to a few hundred thousand kelvins. Spectroscopic study of this high-temperature plasma, peaking its emission in the EUV bandpass, provides one of the best astrophysical laboratories for study of accretion physics. EUV spectra of DNs obtained during outburst are shown in Figures 87*a*–87*c*.

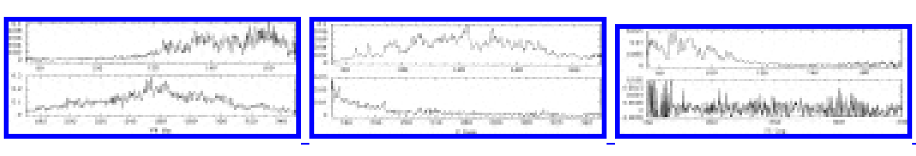

Fig. 87

VW Hydri.—This star shows the softest EUV spectrum of all three DNs observed in outburst to date. The peak in the energy distribution is near 250 Å. However, in VW Hyi, $L_{\rm bl}/L_{\rm disk} \sim 0.2$ (Mauche et al. 1991). Thus, much has yet to be learned from *EUVE* observations of dwarf novae.

U Geminorum.—In the case of U Gem, the total size of the EUV-emitting region during outburst is found to be comparable to that of the WD itself, which indicates that the outburst is mainly confined to the inner disk/boundary layer region (Long et al. 1996). In U Gem, which is an eclipsing system seen at high inclination, emission lines associated with a stellar wind are observed. These wind observations allow the resolution of a long-standing issue about ionization states of CV winds. Evidence of EUV absorption or scattering is also seen in U Gem, attributed to an outer disk bulge at the accretion stream–disk interface. However, the issue is not completely resolved yet, and the absorption could also be due to stream overflow or an increase in the disk thickness (scale height) near the outer rim. In U Gem it is found that $L_{\rm bl}/L_{\rm disk} \sim 1$.

SS Cygni.—This is the hardest of the three DNs during outburst and shows no EUV flux longward of ~130 Å. Mauche, Raymond, & Mattei (1995) present the details of the *EUVE* observation. These authors find that the simple theory that predicts equal luminosities from the boundary layer and the disk, i.e., $\zeta = L_{\rm bl}/L_{\rm disk} = 1$, is strongly violated in this case, yielding $\zeta \lesssim 0.07$. The EUV spectrum of SS Cyg is quite complex and changed by 2 orders of magnitude during the outburst with an almost constant spectral energy distribution. Mauche (1996) also found quasi-coherent oscillations in the *EUVE* data with periods of ~7–9 s.

§6.2. *AM Herculis Stars*

In these types of cataclysmic variable, the accretion stream is magnetically focused onto the white dwarf primary because of the large magnetic fields they possess. The field strengths range from ~10 to 80 MG, with a strength of 250 MG recently discovered in the star AR UMa (Schmidt et al. 1996). The confined accretion stream impacts the white dwarf surface in a small area known as the accretion spot and produces high-energy emission both from a shock slightly above the primary surface and from thermal heating of the surface itself. The spot temperatures are found to be near a few hundred thousand kelvins. Thus, AM Her systems are constant sources of EUV photons. Times of weaker emission, during the so-called low states, occur when the mass transferred from the secondary star falls to a very low value or possibly ceases altogether. See Figures 88*a*–88*i*.

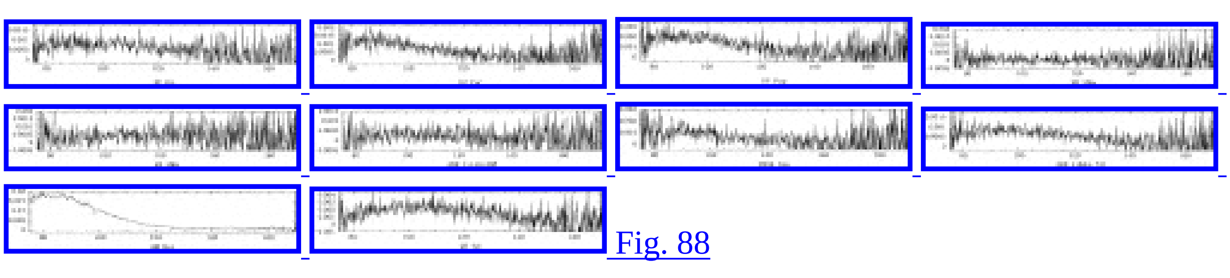

Fig. 88

EF Eridani.—This star shows a typical AM Her–type EUV spectrum, with nonzero flux in the shortest wavelengths observed. There may be indications of line edges caused by highly ionized species. Sirk & Howell (1997) present the EUV light curve and find a spot diameter and height of ~1000 and 120 km, respectively, although EF Eri did not present a simple light-curve shape.

UZ Fornacis.—Warren, Sirk, & Vallerga (1995) used EUV photometry to provide detailed geometric constraints on the accretion spot in this system. They found a spot diameter of less than 2000 km in extent and evidence for extended emission above the white dwarf surface. Sirk & Howell (1997) also found a spot with a vertical height of 200 km and a spot diameter of 1100 km.

VV Puppis.—Vennes et al. (1995b) found that the diameter of the accretion spot was small (250–380 km) and that it had an effective temperature of ~345,000 K. They suggest that absorption lines from O IV may be present. Sirk & Howell (1997) used *EUVE* photometric data to infer a spot diameter of 350 km and spot height of 80 km above the WD surface.

EK Ursae Majoris and *AN Ursae Majoris*.—Both of these sources were extremely weak EUV sources when observed by *EUVE*. They may have been in low states at the time. The spectra show nonzero flux in the shortest wavelengths and may be fittable by a blackbody, possibly with spectral binning in the wavelength direction to enhance the signal. Sirk & Howell (1997) show the EUV light curve of AN UMa.

2RE J1149+288.—Howell et al. (1995) provided the first analysis of EUV photometry for any AM Her star. Their work showed that the accretion spot in 2RE J1149+288 was fairly large, being about 1000 km in diameter. Sirk & Howell (1997) found the spot to be 1008 km in diameter with a height of about 100 km. They also showed that 2RE J1149+288 has a very asymmetric light curve that varied by factors of 2 or 3 in total flux. The EUV spectrum is fairly weak but will likely allow a crude blackbody fit (Mittaz, Mason, & Howell 1997).

V834 Centauri and *2RE J1844-741*.—These two stars show EUV spectra that do not have as much of a turndown at the shortest wavelengths as most of the others. AM Her has a similar appearance although a faster rise at the red end. 2RE J1844-741, like AM Her itself, is suspected of having a relatively weak magnetic field (AM Her ~10 MG; 2RE J1844-741 $\lesssim$ 20 MG), while V834 Cen is near 30 MG. Thus, explaining the spectral shape in 2RE J1844-741 may be possible, at least, in terms of a higher hard X-ray component commonly seen in the lower field AM Her stars. Both spectra show evidence for possible line edges. Sirk & Howell (1997) show the EUV light curve for V834 Cen.

AM Herculis.—This, the canonical AM Herculis star, has the weakest magnetic field of any of these systems, near 11 MG. *EUVE* spectroscopy is discussed by Paerels et al. (1996) who see positive evidence for line edges of highly ionized Ne, but do not detect the expected strong O VI, 2s, 2*p* edges. These authors also find evidence for limb brightening, which indicates the presence of a temperature inversion in the X-ray/EUV atmosphere. Sirk & Howell (1997) find a spot diameter and height of 700 and 100 km, respectively.

QS Telescopii (2RE 1938-46).—This was observed early in the *EUVE* mission during the all-sky survey and was seen to show two transient events, each lasting about 1 hr (Warren et al. 1993). Rosen et al. (1996a) and Rosen et al. (1996b) found that this star presented a dramatically different appearance between the *ROSAT* observations in 1992 and the *EUVE* data obtained in 1994. These authors find a spot temperature of 15 eV from a blackbody fit to the continuum and see evidence for line edges from Ne VI, VII, and VIII.

§6.3. *DQ Herculis Stars*

EUVE has observed two DQ Her stars. These types of cataclysmic variables are systems in which the white dwarf primary has a magnetic field usually weaker than in an AM Her but that is still sufficient to cause a disruption of the inner accretion disk. The DQ Her stars have a partial disk, and the accreted material rains down onto the white dwarf in extended areas or arcs. This inner disk region may be best described as a corona-like volume, producing high-energy photons throughout all orbital phases. The two *EUVE* observations are shown in Figures 89*a* and 89*b*.

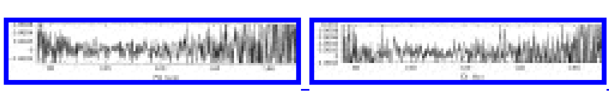

Fig. 89

PQ Geminorum.—Although weak, the *EUVE* spectrum of PQ Gem appears to show some highly ionized emission lines consistent with having their origin in a corona-like region of $10^{5.8}$–$10^{6.0}$ K (Howell et al. 1997). Preliminary analysis of this recently obtained data set also presents a light-curve structure consistent with that seen in X-rays (Duck et al. 1994) and in the UV (Stavroyiannopoulos et al. 1996).

EX Hydrae.—This is an eclipsing DQ Her–type CV. The light curve of EX Hya, when folded onto the 833 s spin period of the WD primary, shows modulation by a factor of 3.7. During the bright portion of the WD spin phase, the EUV spectrum reveals about 20 narrow emission lines (mostly of iron) characteristic of a plasma around 10^7 K. Every line identified in the WD bright phase disappears during the WD faint spin phase and in their stead appear a few tenuous lines indicative of a plasma around 10^6 K (Hurwitz et al. 1997). See Figure 90.

 Fig. 90

ACKNOWLEDGMENTS

We thank the principal investigator, Stuart Bowyer, the *EUVE* science team for their advice and support, and Andrea Frank for editorial support. We also thank Mark Hurwitz and Martin Sirk for providing an EX Hya figure. M. M. acknowledges support from the Royal Society and the Greek Ministry of Research and Technology (PENED program). This research has been supported by NASA contracts NAS 5-30180 and NAS 5-29298, grant NAG 5-2902 to S. B. H., and grant NAGW-2478 to D. S. F. The Center for EUV Astrophysics is a division of UC Berkeley's Space Sciences Laboratory.

FIGURES

 Full image (74kb) | Discussion in text

FIG. 1.—The EUV spectrum of ϵ CMa. The three lower plots show, from top to bottom, the SW, MW, and LW spectra. These have been blocked to bin sizes of 0.13, 0.27, and 0.54 Å, respectively. The top plot shows the three spectra combined, using a uniform spectral bin size of 0.54 Å. The *x*-axes show the wavelength in angstroms, and the *y*-axes show the flux in photons cm^{-2} s^{-1} $Å^{-1}$. Second- and higher order features (if present) have not been removed.

FIG. 41.—Line identifications in the EUV spectrum of Procyon. The plots show, from top to bottom, the SW, MW, and LW spectra. The spectra are unblocked and have bin sizes of 0.067, 0.13, and 0.27 Å, respectively. Selected bright lines are identified by species and wavelength in angstroms. The *x*-axes show the wavelength in angstroms and the *y* axes show the flux in photons cm^{-2} s^{-1} $Å^{-1}$. Second- and higher order features have not been removed and prominent ones are identified.

FIG. 87.—The EUV spectrum of dwarf novae: (*a*) VW Hyi, (*b*) U Gem, and (*c*) SS Cyg. For each source, the SW and MW spectra are shown with bin sizes of 0.2 and 0.4 Å, respectively. Second- and higher order features have been removed as described in the text.

 Full image (35kb)  Full image (33kb)  Full image (34kb)  Full image (33kb)  Full image (41kb)  Full image (39kb)  Full image (34kb)  Full image (31kb)  Full image (16kb)  Full image (33kb) | Discussion in text

FIG. 88.—The EUV spectrum of AM Her stars: (*a*) EF Eri, (*b*) UZ For, (*c*) VV Pup, (*d*) EK UMa, (*e*) AN UMa, (*f*) 2RE J1149+288, (*g*) V834 Cen, (*h*) 2RE J1844-741, (*i*) AM Her, and (*j*) QS Tel. For each source except AM Her, we show the SW spectrum with a bin size of 0.13 Å. For AM Her only, second- and higher order features have been removed as described in the text and the bin size is 0.2 Å.

 Full image (41kb)  Full image (39kb) | Discussion in text

FIG. 89.—The EUV spectrum of DQ Her stars: (*a*) PQ Gem and (*b*) EX Hya. We show the SW spectrum of each with a bin size of 0.13 Å.

 Full image (111kb) | Discussion in text

FIG. 90.—The SW spectrum of EX Hya extracted at the white dwarf bright spin phases (from Hurwitz et al. 1997). Spectral features are marked at the expected wavelength of the species along with the temperatures (log *T*) where each line is predicted to be bright according to Mewe et al. (1995). Also plotted (*smoother curves*) are the 1 σ uncertainties at each wavelength.

EUVE Atlas of Stars

This page takes you to a table containing EUVE (Extreme Ultraviolet Explorer Data) spectra of 94 stars selected by Craig et al. (1997). The list is roughly representative of the sample of stars by the EUVE project during its lifetime (1992-January 2001). These spectra were taken whenever possible with all the three bandpasses, short- (SW; 70-190 Å), medium- (MW; 140-380 Å), and long-wavelength (LW; 280-760 Å). The spectral resolutions for these cameras are 0.5, 1, and 2 Å, respectively.

The stars are organized in a table by spectral type and by subcategories within each type. A user may click on the 'ps' link to browse a multi-panel image or one of the three bandpass links to download the data in compressed FITS format. The x-axis is in wavelength units, while the y-axis is in units of photons/cm^2/s/Å).

It is important to point out that the spectra in this atlas were only the best available at the time of the compilation. In some cases longer exposures were made after the atlas was constructed (late in the mission lifetime) and are available in the HEASARC/MAST archives.

Available Data

A HIGH DISPERSION SPECTROSCOPIC SURVEY OF THE HOT WHITE DWARFS: THE *IUE* NEWSIPS SWP ECHELLE DATA SET

FOS

Faint Object Spectrograph

The Faint Object Spectrograph (FOS) was one of the original 4 axial instruments on the Hubble Space Telescope (HST). The FOS, which was removed from HST during the Second Servicing Mission in February 1997, was used to make spectroscopic observations of astrophysical sources from the near ultraviolet to the near infrared (1150-8000 Angstroms).

ST-ECF Post Operational HST Archives

The Post-Operational Archives (POA) branch of the Space Telescope - European Coordinating Facility (ST-ECF) has taken over the main responsibility of FOS (re-)calibration. Their web pages contain all of the information that was previously on the STScI FOS pages, supplemented with more recent FOS news including a new and improved version of the FOS calibration pipeline (POA_CALFOS), which replaces CALFOS in the standard IRAF/STSDAS FOS calibration. We invite you to check out their web pages.

Received 1996 April 22; accepted 1996 August 16

ABSTRACT

We construct a composite quasar spectrum from 284 *HST* FOS spectra of 101 quasars with redshifts $z > 0.33$. The spectrum covers the wavelengths between 350 and 3000 Å in the rest frame, with a peak S/N level of ~130 per Å at ~1200 Å. Since ~90% of the sample quasars have redshift $z < 1.5$, the spectrum is suitable for studying the wavelength region shortward of Lyα without large effects from intervening Lyα forest absorption. Data in the waveband between 350 and 600 Å are mainly from the spectra of $z > 1.5$ quasars, for which significant corrections for the accumulated Lyman-series line and continuum absorption have been applied.

There is a significant steepening of the continuum slope around 1050 Å. The continuum between 1050 and 2200 Å can be modeled as a power law $f_\nu \propto \nu^\alpha$ with $\alpha = -0.99 \pm 0.05$. For the full sample the power-law index in the extreme ultraviolet (EUV) between 350 and 1050 Å is $\alpha = -1.96 \pm 0.15$. For the radio-loud subsample (60 objects), the EUV spectral index is $\alpha \simeq -2.2$, while for the radio-quiet subsample (41 objects) it is $\alpha \simeq -1.8$. The continuum flux in the wavelengths near the Lyman limit shows a depression of ~10%. The break in the power-law index and the slight depression of the continuum near the Lyman limit are features expected in Comptonized accretion-disk spectra. Comptonization produces a power-law tail in the wavelength band shortward of ~1000 Å and smears out the Lyman-limit edge of the intrinsic accretion-disk spectrum.

In the EUV waveband, we detect several possible emission features, including one around 690 Å that may be O III + N III produced by the Bowen fluorescence effect. Comparing our composite spectrum with one made at higher redshifts by Francis et al., we find that the equivalent widths of Lyα and high-ionization emission lines are larger in our sample, reflecting a known luminosity dependence. The equivalent widths of low-ionization lines do not exhibit such a dependence, suggesting that the quasar EUV continuum above ~50 eV is steeper at higher luminosity.

Radio-quiet quasars appear to show a slightly harder continuum and lower ionization levels in their emission lines.

Subject headings: atomic processes—quasars: general—ultraviolet: galaxies

FOS Composite Quasar Spectrum

This is a mean quasar spectrum, between 350 and 3000 Å, constructed from 2 84 FOS obser vations of 101 quasars with redshifts $z > 0.33$, as described in **Zheng, W., et al. 1997 ApJ,475,469**, from the 1 Feb issue of *The Astrophysical Journal*. This reduced archival data is made available courtesy of Wei Zheng .

The spectrum is available as a flat ASCII file:

- **Uncompressed** (409.96 kbytes)
- **Unix compressed** (93.087 kbytes)
- **gzip compressed** (78.277 kbytes)

(Your browser should attempt to save the above files to disk, rather than displa ying them.)

The table columns are:

- **Rest wavelength (Å)**
- **Relative flux F(λ)**
- **Error**
- **RMS**

GHRS Observations of 10 Lac

Wavelength range (Å)	Observation Rootname	Reduced GHRS Data	Line ID List	Atlas Fig. #
1180-1350	Mosaic-1	Data	IDs	1
1350-1500	Mosaic-2		IDs	1
1500-1650	Mosaic-3		IDs	1
1650-1780	Mosaic-4		IDs	1
1181-1199	Z2MB010D	Data	IDs	2a
1199-1217	Z2MB010G		IDs	2b
1210-1228	Z2MB010H	Data	IDs	3a
1229-1247	Z3650308		IDs	3b
1238-1256	Z2MB010I	Data	IDs	4a
1256-1274	Z365030B		IDs	4b
1266-1284	Z2MB010L	Data	IDs	5a
1284-1302	Z3650307		IDs	5b
1294-1312	Z2MB010M	Data	IDs	6a
1312-1330	Z0IX010R		IDs	6b

Bibliographic Code: 1995ApJ...449..488R

Abstract

The determination of the incidence and column density distribution of damped Lyα systems from QSO absorption-line surveys in the redshift interval $0 < z < 1.65$ is crucial for constraining the evolution of neutral gas in galaxies. This redshift interval corresponds to a time interval of ~62% of the age of the universe for $q_0 = 0$ (77% for $q_0 = 0.5$). However, because damped Lyα systems are relatively rare in spectra, a sensitive UV spectroscopic survey would consume considerable telescope time. We have therefore undertaken a new approach that takes advantage of the fact that all damped Lyα systems studied so far are found to have corresponding Mg II metal-line absorption. For redshifts $z < 1.65$ we have used available UV data to study the Lyα absorption line corresponding to 43 Mg II systems. After accounting for possible biases, we find that at a mean redshift of $\langle z \rangle = 0.8$ the number of damped Lyα absorption lines with neutral hydrogen column density $N(\mathrm{H\ I}) \geq 2 \times 10^{20}$ cm^{-2} per unit redshift is $n_{\mathrm{DLy}\alpha}(z = 0.8) \leq 0.12$. A similar analysis based on studying the Lyα line in Lyman-limit systems is consistent with this result.

This limit on the observed number density at $z \approx 0.8$ is consistent with the trend at higher redshift as well as the number density at the current epoch inferred from H I cross sections of nearby disk galaxies. The result that $n(z)$ in the redshift interval $0 < z < 1.65$ conforms to a trend established by three different observing techniques over three redshift regimes provides evidence that this trend actually traces the evolution of neutral gas in galaxies. The data at $z > 1.65$ combined with the constraint from nearby galaxies at redshift $z = 0$ result in a parameterization that is valid from redshift $z \approx 4$ to the present epoch: $n_{\mathrm{DLy}\alpha}(z) = (0.015 \pm 0.004)(1 + z)^{2.27 \pm 0.25}$. The power-law index of 2.27 ± 0.25 indicates that damped Lyα absorbers undergo evolution, either in size or in number density, from a redshift of about 4 to the present epoch.

StarView version 7.0 is now available

StarView is an astronomical database browser and research analysis tool. Developed in Java, StarView provides an easy to use, highly capable user interface that runs on any Java enabled platform as a standalone application.

The main tasks starview is used for are:

1. Searching the MAST archive for scientific data including HST, FUSE, IUE, and EUVE data.
2. Examining the calibrations used for a particular data set
3. Looking at proposal information for past HST projects

New features in StarView version 7 include:

- Multiple archives available in StarView (HST, IUE, FUSE, EUVE and more to come)
- Improved "smart" cross qualification now can automatically cross qualify on coordinates or object name
- Ability to enter coordinates in equinox other than J2000 in the Target Resolver tool (query's are still done in J2000 and results are diplayed in J2000)
- Improved performance (faster queries)
- Retrieval now loaded from the archive at run-time so changes in retrieval do not require an upgrade to the program
- Save SQL allows user to have StarView create SQL for them to use in another environment or to see how a query is being done
- Attribute table formatting can now be saved with the form so when you select the table button from a form, the resulting table view of the results will be in the saved field order and column widths
- Pull-down menus are restructured to include all button bar functionality with associated hot keys to allow for more keyboard driven functionality
- Recent news from the archives and StarView is now available. News items are displayed upon startup if there is new or unread information. News items are always accessible from the Tools pull-down menu
- Once available, StarView will support th enew retrieval options such as CD and DVD

[Download and install] the latest StarView.

For information on Reaction Wheels, see Frequently Asked Questions about Reaction Wheels.

For Phase 1 proposal questions, see Phase 1 Frequently Asked Questions.

Astrophysics Data Facility

The Astrophysics Data Facility (ADF), located at the NASA Goddard Space Flight Center (GSFC), is responsible for designing, developing, and operating data systems that support the processing, management, archiving and distribution of NASA mission data. The ADF serves three broadly-defined astrophysics disciplines: high-energy astrophysics, UV/optical astrophysics, and infrared/submillimeter/radio astrophysics. The ADF, part of the Space Science Data Operations Office (SSDOO), collaborates with the GSFC Laboratory for High Energy Astrophysics (LHEA) and the Laboratory for Astronomy and Solar Physics (LASP) in managing data for specific missions. The ADF staff also support the astrophysics community's access to multi-mission and multi-spectral data archives in the National Space Science Data Center (NSSDC).

ADF Facilities and Services

- AscaDF: Advanced Satellite for Cosmology and Astrophysics (ASCA) Data Facility
- ADC: Astronomical Data Center
- COBE: Cosmic Background Explorer (COBE) Project
- FITS: Flexible Image Transport System Support Office
- IRAS: Infrared Astronomical Satellite Archive Interface
- MDSS: Mission Data Staging System
- USRSDC: U.S. Roentgen Satellite (ROSAT) Science Data Center
- WISARD: Web Interface for Searching Archival Research Data
- XSDC: X-ray Timing Explorer (XTE) Science Data Center

Astrophysics Data Facility Data Search and Access Tools

- AMASE: Astrophysics Multi-Spectral Archive Search Engine
- IMPReSS: IMage PeRimeters of Sky Surveys
- WISARD: Web Interface for Searching Archival Research Data

About CADC

The **CADC** is located at the Dominion Astrophysical Observatory in Victoria, B.C., Canada, part of the Herzberg Institute of Astrophysics under the National Research Council of Canada.

The **CADC** was established in 1986 as one of three world-wide distribution centres for data from the Hubble Space Telescope HST archive is possible trough a grant from the Canadian Space Agency.

Most of the CADC software development is done in collaboration with the European Southern Observatories located in Garching, near Munchen, Germany and the Space Telescope - European Coordinating Facilities .

The CADC is also responsible for archiving data from the Canada France Hawaii Telescope.

If you used the CADC for your research, please include the following acknowledgment:

Guest User, Canadian Astronomy Data Centre, which is operated by the Herzberg Institute of Astrophysics, National Research Council of Canada.

If you want to know more about the CADC mandate.

Policies and Registration

Any users are free to download and run our software. There is no charge to browse through the different catalogues and to use the preview system.

However, in order to retrieve archive data, users must register. **Please read our data distribution policy before registering**. Use this form to register.

Here is the CADC staff

ST-ECF

The ESO/ST-ECF Science Archive is a joint collaboration of the European Southern Observatory (ESO) and the Space Telescope - European Coordinating Facility (ST-ECF).
ESO observational data can be requested after the proprietary period by the astronomical community of the ESO member states and Chile. Please read the official 'ESO Data Access Policy' statement for more information.
The entire HST archive is available world-wide. To request data you have to register as an ESO/ST-ECF Archive user. Please acknowledge the use of archive data in your publications.

News and updates

- **UVES query screen is now available.**
- **ESO PI service mode data distribution to take place primarily on DVD starting with Period 68.** A description of the compatibility of our disks with common DVD readers is available.
- **Query forms to access the VLT Science Archive:**
  - A new WFPC2 association scheme is in place. We are still working issues related to the background to the edges of the products.
  - A General form, specially suitable when searching across wavelength range.
  - A FORS1 and a FORS2 forms, giving access to optical images and spectra.
  - An ISAAC form, giving access to the stacks of frames observed in the infrared.

  These new query functions feature FITS headers viewers, DIMM seeing viewers, together with automatic selection of suitable calibrations for FORS1, FORS2, ISAAC and UVES data

- Dedicated Page with the Public Datasets now including **VINCI** commissioning data.
- Stand-alone FITS tools in ANSI-C available. Among the tools, `hierarch28` can convert `HIERARCH ESO` header keywords to IRAF keywords.
- Having trouble using the Science Archive Facility? Pay a visit to our FAQ section (frequently asked questions).
- The Archive Brochure, advertising our services, available in PDF format (1.1MB).

HOME INDEX SEARCH HELP NEWS

Collaborations of ESO and ST-ECF Archive staff members with the Canadian Astronomy Data Centre (CADC) and the Centre des Données astronomiques de Strasbourg (CDS) take place in the areas of software development and data reduction.

For comments or help, e-mail: ledas-help@star.le.ac.uk

Welcome to LEDAS (LEicester Database and Archive Service)

LEDAS provides an on-line astronomical database service and access to archive data from high energy astrophysics missions. In particular, **LEDAS** provides the primary means of access for the UK astronomical community to the ROSAT Public Data Archive, the *ASCA* Public Data Archive, the *Ginga* Products Archive and now to the Chandra Science Archive.

NEW USERS: For an overview of the services provided by **LEDAS**, user guides, contact details and further help, please see the INFO section of the **LEDAS** site. To go directly to any of our mission archives, software distribution sites or other services, click on the relevant link in the navigation bar.

The **ADC** has been an important resource for astronomy data, catalogs, and journal tables since 1977. We have thousands of published data sets available.

If your research benefits from the use of ADC's services, please acknowledge the ADC in your publication to ensure continuation of our services. See our recommended acknowledgement for suggested wording.

It is with profound sadness that we announce the untimely death of our dear friend and colleague, Dr. Thomas J. Sodroski, who worked at the ADC from 1998 until January 2002. Please visit our **"Tribute to Tom Sodroski" web site**.

Astronomical Software & Documentation Service

Welcome to ASDS, a collection of on-line astronomical documents indexed for full-text searching.

The **software collection** is made up of:

Packages: Packages have a description page, outlining their capabilities, requirements, and availability. Search them for general properties. Browse to see everything.

Documents: The document collection consists of user guides, programmer guides, on-line help files, etc., made available by the software providers. Search the document collection to find more detailed requirements. Search results are linked to the associated package description. (Not all packages have associated documents).

The **telescope manuals collection** NEW! consists of

Sites: Each site has a description page, with links to more information, and thumbnail sketches of each manual in the collection. Search the site descriptions for general information.

Manuals: Telescope manuals, intrumentation manuals, and user guides, indexed for searching. Search the manuals collection for particular requirements.

FUSE is a NASA-supported astronomy mission that was launched on June 24, 1999, to explore the Universe using the technique of high-resolution spectroscopy in the far-ultraviolet spectral region. The Johns Hopkins University has the lead role in developing and now operating the mission, in collaboration with The University of Colorado at Boulder, The University of California at Berkeley, international partners the Canadian Space Agency (CSA) and the French Space Agency (CNES), and corporate partners. **FUSE** is part of NASA's *Origins* Program under the auspices of NASA's Office of Space Science.

OGLE

THE OPTICAL GRAVITATIONAL LENSING EXPERIMENT

1.3m Warsaw Telescope - Las Campanas Observatory, Chile
(control building to the left)

- The main OGLE Homepage in Warsaw
- The mirror OGLE Homepage in Princeton (faster for US users).
  Please note the US server change.

** OGLE (III) IS BACK IN OPERATION **

On the night of June 11/12 2001, the Optical Gravitational Lensing Experiment entered its third phase, OGLE III, and resumed regular observations at the Las Campanas Observatory, Chile. Observations are collected with the new "second generation" CCD mosaic camera, commisioned in May 2001. The 8kMOSAIC camera consists of eight thin SITe 2048x4096 CCD chips (8192x8192 pixels of 0.26"/pixel) giving the total field of view equal to 35' x 35'. The readout time of the camera is 98 seconds with readout noise of 6-9 e (depending on chip) and the gain of 1.3 e/ADU.

INES

IUE Newly Extracted Spectra

INES Principal Centre

Welcome to the INES Principal Centre operated by the Laboratory for Space Astrophysics and Theoretical Physics (LAEFF)

INES stands for "IUE Newly Extracted Spectra". The purpose of the INES System is to reach the maximum number of scientists and to provide IUE spectra in a form that does not require a detailed knowledge of the instrumental characteristics. INES data have been obtained through processing of the IUE Final Archive output products. The INES distribution system is structured in three levels: a Principal Centre (and its Mirror), several National Hosts and unlimited End Users [more...].

What is new in INES VERSION 3.0

The INES PR Brochure [choose the lenguage] New!

The NASA ADS now includes links to INES spectra [see details]

Spanish INES Data Server (Version 3.0)	INES National Hosts

The INES System	INES FAQ
INES Scientific Papers New!	Publications
Examples of use of INES Data	How to read INES Data
About IUE	INES in the Media
INES Principal Centre Staff	INES Usage Statistics

Final Archive data are temporarily supplied through the NEWSIPS Data Server.

The INES System has been developed by the ESA IUE Project at VILSPA. Data and access software are distributed and maintained by INTA through the INES Principal Center at LAEFF.

Please, send your comments and questions to the INES HelpDesk

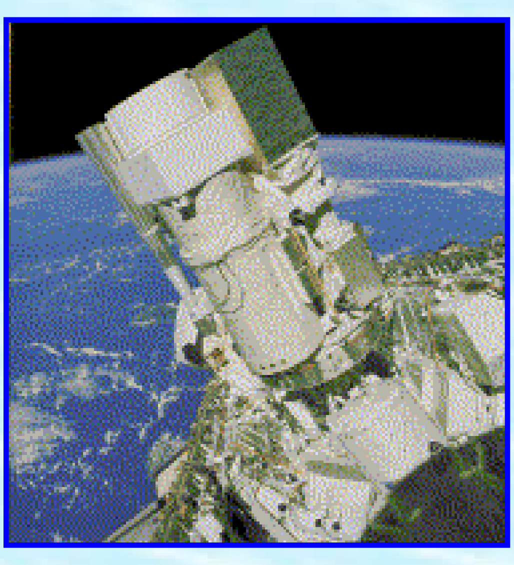
The Hopkins Ultraviolet Telescope Project



ASTRO-1 *ASTRO-2*

This page has been reconfigured with NETSCAPE enhancements...
but the previous version is still available.

[What is HUT?] [Astro Observatory] [Science Results] [Publications]
[Personnel] [Photo Gallery] [Technical Info] [Spectral Atlas]

Welcome to the home page of the Hopkins Ultraviolet Telescope (HUT) project at The Johns Hopkins University. HUT was conceived, designed, and built by astronomers and engineers at JHU to perform astronomical observations in the far-ultraviolet portion of the electromagnetic spectrum, wavelengths of light that are inaccessible to ground-based telescopes.

HUT's primary purpose is to observe wavelengths of light that are too short to be seen with the Hubble Space Telescope, although overlap is provided to allow direct comparison. The telescope has flown twice aboard the space shuttle, once in December 1990 and again in March 1995, as part of a package of instruments called the Astro Observatory. HUT has been used to observe hundreds of objects, ranging from nearby stars and planets to the most distant objects known in the Universe, the quasars.

Using the buttons below, you can access a wide range of popular level information about the telescope and its two space shuttle flights. Links to technical information are provided for those who are interested in more detail. We hope you enjoy browsing these pages and learning about HUT.

- **What is HUT and What Does it Do?**
  Click here to learn more about the telescope, what it was designed to do, and why. Includes line diagrams and photos as part of your personalized guided tour!

- **HUT and the Astro Observatory**
  This section places HUT in the context of the Astro Observatory, describing some of the project's history, and providing links to information about the other instruments in the package. Special pages specific to the Astro-1 and Astro-2 missions are also available.

- **Scientific Results from HUT**
  Click here to learn about some of the exciting results achieved with HUT, described at a popular level. Links to more technical descriptions are provided. This section is weighted toward Astro-1 results, but Astro-2 information is being added as it becomes available, so watch this space!

- **Publications involving HUT**
  This section contains reference listings for all of the articles published or in press that report findings from HUT. Many of the articles have abstracts on-line and we are working to get the entire papers on line, especially for papers currently being added. Click here to get right to the Astro-2 papers!

- **The People Who Made it Happen**
  Use this page to learn about many of the people involved in designing, building, and flying HUT on the space shuttle.

- **The Photo Gallery**
  Although photos are linked in elsewhere throughout our pages, we have assembled the best in one place! Check out images of the launches, the astronauts and telescopes on-orbit, and various earth views.

- **Technical Information About HUT**
  Project personnel (or interested bystanders) can use this button to get directly to technical information about the telescope and/or data reduction.

- **HUT Quick Look Spectral Atlas**
  Many of the spectra obtained with HUT during Astro-1 are on-line. The top page contains links to "example" spectra of various types of objects for the casual user. A separate page will allow you to search the actual observation log and select specific objects of interest.

More information on HUT and the Astro missions is available at these sites:

- Marshall Space Flight Center
- Kennedy Space Center (STS-35, Astro-1)
- Kennedy Space Center (STS-67, Astro-2)
- The Johns Hopkins University Office of News and Information

Want to know more about how astronomers analyze light and actually learn about distant objects in the Universe? Check out the educational Web site:

"What are Those Squiggly Lines? Learning from Light"
put together by HUT astronomer Bill Blair.

Wisconsin Ultraviolet Photo-Polarimeter Experiment

The Wisconsin Ultraviolet Photo-Polarimeter Experiment (WUPPE) was a pioneering effort to explore polarization and photometry in the ultraviolet (UV) spectrum. It was the first and most comprehensive effort to exploit the unique powers of polarimetry at wavelengths not visible on Earth. The instrument was designed and built at the University of Wisconsin Space Astronomy Laboratory in the 1980's.

WUPPE flew on two NASA Space Shuttle missions: ASTRO-1 and ASTRO-2. WUPPE was one of three ultraviolet telescopes (the Hopkins Ultraviolet Telescope (HUT) and the Ultraviolet Imaging Telescope (UIT) were the others) and one x-ray telescope (the Broad Band X-Ray Telescope (BBXRT)) on the ASTRO-1 payload which flew aboard the Space Shuttle Columbia December 2 -11, 1990. WUPPE, HUT & UIT were reflown in March 2 -18, 1995 on board the Space Shuttle Endeavour which set the record for the longest Shuttle mission at that time (16 days).

WUPPE-1 and WUPPE-2 obtained ultraviolet spectropolarimetry (and spectra) for 121 objects (183 observations) and spectra-only for 65 objects (77 observations).

WUPPE has been retired and is now on display at SpacePlace, the Department's public outreach facility.

The UW Pine Bluff Observatory(PBO) spectropolarimeter (HPOL) provides key ground-based observations in support of WUPPE.

Principal Investigator: Dr. Arthur D. Code

WUPPE is supported by NASA contract NAS5-26777.
This page has been accessed times since October 28, 1996.

The WUPPE web site is maintained by Marilyn Meade .

ASDC responsibilities

- Support ASI scientific missions for all matters concerning the management and the archival of scientific space data
- Generate and maintain a permanent data archive of all ASI scientific missions
- Act as the interface between the ASI scientific missions and the users' community
- Support the Italian (and the general) community in the field of data analysis and archival research
- Maintain a permanent scientific and technical expertise for the processing and interpretation of the data hosted
- Provide on-line access to the data hosted
- Host a copy of non-ASI public data archives that are of interest in the Italian scientific community
- Develop and maintain (also in collaboration with other institutions) software systems for the access, analysis and comparison of archival data
- Establish links with other data centers for the exchange of public data, software and expertise

The ASDC is located at the European Space Agency's establishment of ESRIN, Frascati, Italy

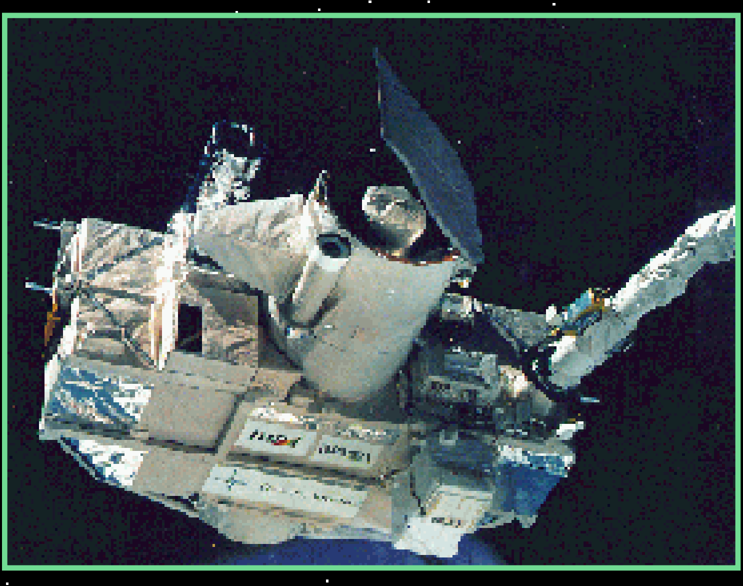
THE BERKELEY EXTREME AND FAR-ULTRAVIOLET SPECTROMETER (BEFS)



Welcome to the home page of the Berkeley Extreme and Far-Ultraviolet Spectrometer (BEFS), a project of the Space Astrophysics Group of the University of California, Berkeley. Designed for high-resolution spectroscopy in the far and extreme ultraviolet, BEFS flew in space twice, in 1993 and 1996. BEFS is part of ORFEUS, the Orbiting and Retrievable Far and Extreme Ultraviolet Spectrometers, a joint project of NASA and the German space agency.

NEW! BEFS spectra from both the 1993 and 1996 missions are now available from the Multimission Archive at STScI (MAST).

- For a good overview of the ORFEUS-II mission, thumb through the 10 June 1998 issue of the Astrophysical Journal (Letters), dedicated to first results from the Berkeley spectrometer.

ORFEUS is a 1 m normal incidence telescope for spectroscopic investigations of cosmic sources in the far and extreme ultaviolet spectral range.
The instrument is integrated into the freeflyer platform ASTRO-SPAS.

ORFEUS-SPAS I was launched Sept. 12, 1993 with space shuttle DISCOVERY on mission STS-51.

ORFEUS-SPAS II was launched Nov. 19, 1996 with space shuttle COLUMBIA on mission STS-80.

The project is part of a collaboration between the Federal Republic of Germany represented by DARA (now DLR) and the United States of America represented by NASA.
The scientific institutes participating in the development of the instruments and the scientific preparations of the mission are:

Institute for Astronomy and Astrophysics (Department Astronomy) of the University of Tübingen

- Scientific Project Management
- Development and construction of Echelle Detector and Echelle Electronics

Landessternwarte Heidelberg (LSW)

Next Generation Space Telescope

A Key Element in NASA's Origins Program

NGST Short Cuts: Short Cuts...

Home | News | Science | Technology | Project Office | FAQs | Search

This is NASA's official web site for news and information about the space agency's Next Generation Space Telescope (NGST), a powerful space telescope that will replace the highly successful Hubble Space Telescope (HST) when it retires near the end of this decade. Scheduled for launch in 2009, the telescope will carry cameras and spectrographs sensitive to infrared radiation. Over the telescope's 5-10 year lifetime astronomers hope to observe the farthest reaches of the universe.

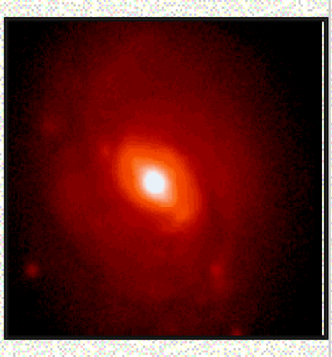
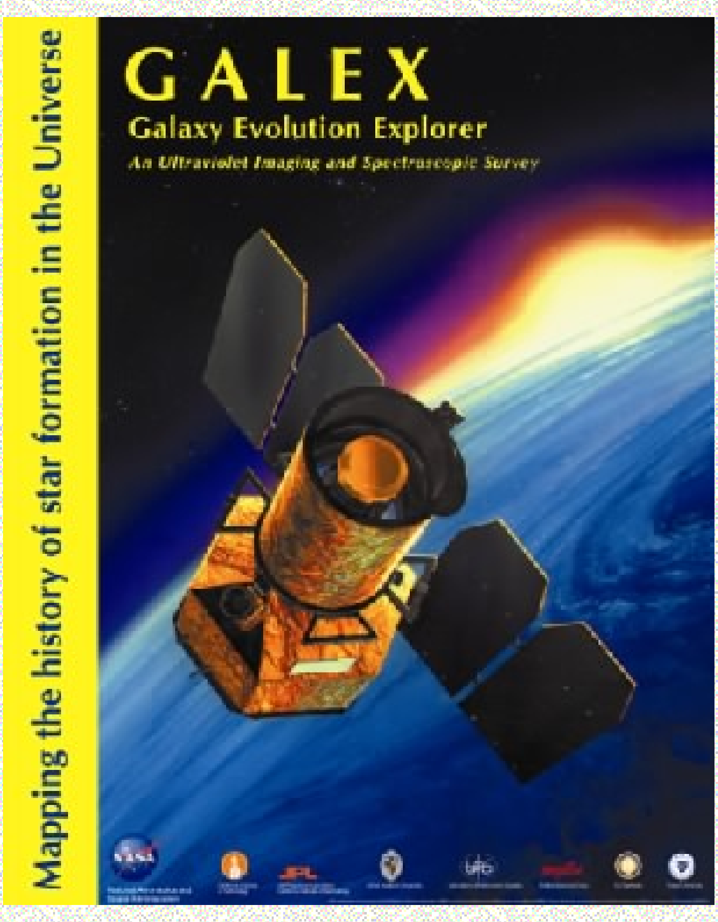
GALEX - The Galaxy Evolution Explorer



GALEX, the Galaxy Evolution Explorer, is a NASA UV imaging and spectroscopic survey mission designed to map the global history and probe the causes of star formation and its evolution over the redshift range 0<z<2.



Science: History of star formation over 0<z<2, 80% of history of universe, when galaxies & gas evolve dramatically. Z=0 UV investigation.

Technical: UV 1350-3000Å, 50 cm telescope, 2 Microchannel plate detectors, Rotating grism

Mission: Launch May, 2002. Pegasus XL, 28 month mission, 3-axis S/C, nighttime exposures, all-sky survey, deep surveys, 28 deg/690 km orbit, X-band ground station

Data Release: 2003-2004

Cosmic Hot Interstellar Plasma Spectrometer

A University-Class Explorer (UNEX) Mission

The Cosmic Hot Interstellar Plasma Spectrometer (CHIPS) is a University-Class Explorer (UNEX) mission funded by NASA. It will carry out all-sky spectroscopy of the diffuse background at wavelengths from 90 to 260 Å with a peak resolution of $\lambda/150$ (about 0.5 eV). CHIPS data will help scientists determine the electron temperature, ionization conditions, and cooling mechanisms of the million-degree plasma believed to fill the local interstellar bubble. The majority of the luminosity from diffuse million-degree plasma is expected to emerge in the poorly-explored CHIPS band, making CHIPS data of relevance in a wide variety of Galactic and extragalactic astrophysical environments. The CHIPS instrument will be carried into space aboard CHIPSat, a dedicated spacecraft to be built by SpaceDev, Inc., and launched from the second stage of a Delta rocket in April of 2002.

Page last updated: September 6, 2000

For more information about CHIPS please send an e-mail to Dr. Mark Hurwitz. If you have questions about or problems with this web page, please send an e-mail to the webmaster.

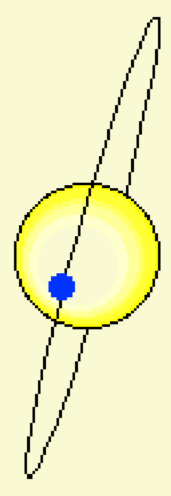
Welcome To The *Kepler Mission*

What is the *Kepler Mission?*

It is a special purpose space mission in the NASA Headquarters Discovery Program for detecting terrestrial planets, that is, rocky and Earth-size around other stars.

How can extrasolar terrestrial planets be detected?

When a planet passes in front of its parent star, as seen by us, it blocks a small fraction of the light from that star. If the dimming is truly caused by a planet, then the transits must be repeatable. Measuring three transits all with a consistent period, duration and change in brightness provides a rigorous method for discovering and confirming planets - planets even smaller than the Earth.



From the brightness change the planet size can be calculated. From the period the orbital size can be calculated and the planet's temperature estimated.

Kepler was selected

as one of the two new Discovery missions ! ! ! !

See the NASA Ames press release
and the NASA Headquarters press release

The following is a Table of Contents = Site Map

Kepler Mission Description:

Status:

Kepler was selected on Dec 21, 2001 as one of the next two Discovery missions ! ! ! !
See the NASA Ames press release, the NASA Headquarters press release and the Discovery Newsletter.

On July 20, 2001 NASA HQ received our Concept Study Report (Step 2 proposal) for the the next new Discovery Mission. Two competing proposals (Dawn and Inside Jupiter) were also due by July 24.

On Mar 22, 2001 a kick-off meeting was held at NASA HQ for the three candidate missions to begin their 4 month studies leading to a down-selection of one mission for flight.

On Jan 4, 2001 the *Kepler Mission* was selected as one of three candidate missions for the next Discovery mission. Final selection for flight will be done towards the end of 2001. See the attached NASA HQ Announcement. Further details are contained in the NASA Ames Press Release

We have updated this web site to reflect what has been proposed to NASA.

We received funding in 1999 to perform a technology demonstration. This is described in several new papers on the Technical Papers page and in several new web pages Technology Demonstration.

Renewal of the Director of Launchers mandate

22 March 2002 PR N° 17-2002 At its 156th meeting, held on 20 and 21 March in Paris, the ESA Council decided to renew the terms of office of Jean-Jacques Dordain, Director of Launchers, for a period of four years, from 1 May 2003 to 30 April 2007.

What is the SSDS?

The Space Science Data System is the confederation of groups supported by NASA's Office of Space Science to provide public access to and to ensure the usability of science data from OSS missions and selected other data. Some SSDS groups develop tools and services for finding and using these data. Long-term data accessibility is ensured by SSDS archiving and preservation of the data.

Who are SSDS' customers?

The SSDS customer community ranges from the NASA and international space science research communities to students, educators and the general public.

ADCCC

Astrophysics Data Centers Coordination Council

Site Search

The Astrophysics Data Centers Coordination Council is comprised primarily of representatives from the NASA's major astrophysics data centers. The key activities of the ADCCC include:

- **Improving the interoperability of the services offered** by the individual data centers, making it easier and more practical to carry out interdisciplinary research in astrophysics.
- **Establishing and/or enhancing archive interface standards**.
- **Shared development of data access tools and utilities**.
- **Advising NASA HQ on guidelines for mission archive requirements** and data standards.

In addition, the ADCCC explores mechanisms to extend connections to other Space Science disciplines, through interaction with the Space Science Data Systems Technical Working Group.

At the end of 2001, the ADCCC was restructured as the Astrophysics Data Centers Executive Council (ADEC). The ADEC page gives more information regarding the reorganization and new priorities.

FUSE Data Analysis

CalFUSE v2.0 Is Here!

CalFUSE v2.0, the FUSE calibration pipeline, is now available for general use. It features the following improvements over v1.8.7:

- Corrected heliocentric wavelength scale
- Detection and removal of event bursts
- Walk correction (for low-pulse-height events)
- Improved scattered-light model
- Astigmatism correction
- Optimal (weighted) spectral extraction
- Improved wavelength and flux calibrations

For more information or to download the software, see the CalFUSE homepage.

Software

We have written several IDL routines to read and display FUSE data (11/06/2000). The spectral manipulation program XIPLOT, an IDL-based program, is available at the French FUSE site (2/20/2001).

Using IRAF to Manipulate FUSE Data, a PDF file from Jerry Kriss (from the Data Workshop, see below).

IRAF scripts: Some IRAF scripts from Jerry Kriss to go with the IRAF/FUSE demo (5/31/2000).

CalFUSE v2.0.5 is now the standard version of the FUSE calibration pipeline software package (10/10/2001).

v_{HEL} correction Discussion of v_{HEL} correction error in CalFUSE prior to v2.0. NEW (7/16/2001)

Steve McCandliss's H2ools page. All sorts of tools and support materials for modeling molecular hydrogen (3/06/2001).

Documentation

FUSE Data Handbook, version 1.1 can be viewed on-line or downloaded. Dated 2/08/2000.

Mission Planning Schedule Timeline Plots, Use these plots to see when each of your exposures were taken (in orbital day/night, SAA, limb angle, etc)

The CalFUSE Pipeline Reference Guide, v1.1, provides detailed information on CalFUSE v2.0.5.

Reference Guide for the FUSE IDL tools, provides detailed information on the availability and use of the IDL based tools for data inspection and analysis. Routines include FUSE_SCAN for display and manipulation of the 2D raw data as well as FUSE_ANALYSIS for analysis of the 1D extracted data. By Don Lindler, Dated February 14, 2001.

FUSE Data Analysis Cookbook, version 1.0 can either be viewed on-line or downloaded. Dated 2/19/2001.

Miscellaneous

High Resolution FUV Spectroscopy of Terrestrial Day Airglow with FUSE, a paper on FUSE observations of airglow lines published in the Journal of Geophysical Research, 106, 8119 (2001), by Feldman et al. In addition, here are 2 additional plots of orbital daytime airglow spectra which are extensions of figure 7 in this paper. In these plots, the top panel (a) contains spectra of the earth limb, the middle panel (b) is "downward looking" spectra, and the bottom panel is "sideways or upward looking" spectra: figure 1, and figure 2.

FUSE Airglow Spectra, Downloadable "upward looking" FUSE airglow spectra

FAR ULTRAVIOLET SPECTROSCOPIC EXPLORER

GUEST INVESTIGATOR PROGRAM

Goddard Space Flight Center

Welcome to the FUSE Guest Investigator Program Homepage

The FUSE Science and Data Workshop will take place at Johns Hopkins University during 2002 March 2022. See the abstract book, meeting schedule, and other important details here.

FUSE is back in business! As of March 1st, FUSE has resumed science operations. Regular updates on FUSE's status are posted at the Current FUSE Mission Status website at the FUSE Science Center at Johns Hopkins University.

For further information on FUSE activities since launch, please see this table of important dates.

This is the official website for the FUSE Guest Investigator (GI) Program. The GI program is administered jointly by NASA Headquarters and the NASA Goddard Space Flight Center.

The list of items in the frame to the left provides a site guide for navigating the information available on this website.

Generally, your best source for technical information on FUSE will be the JHU FUSE Science Center at the Johns Hopkins University in Baltimore, Maryland.

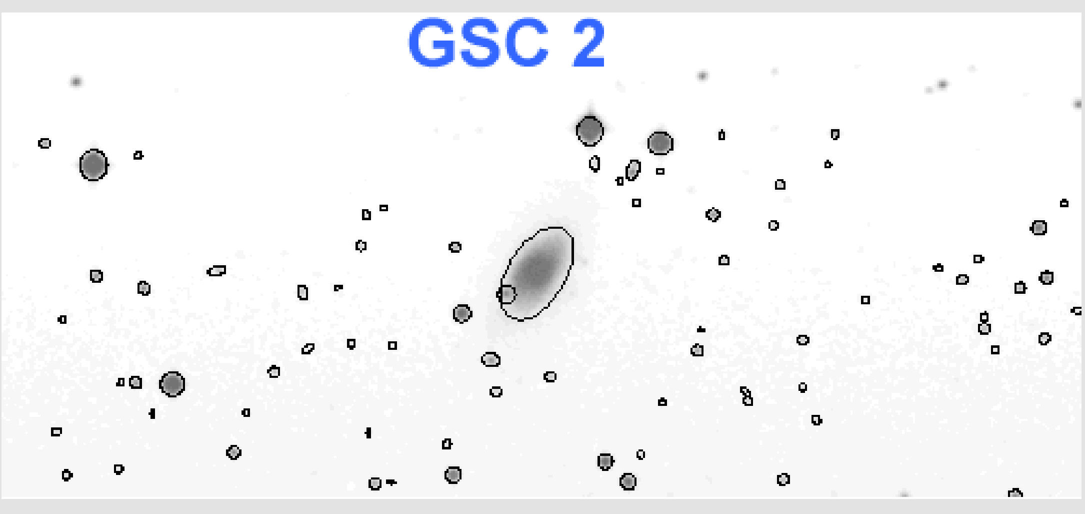
GSC-I	GSC-II	GSC2.2 Release Notes	Background	Plate Material	Catalog Properties	Data Access

998,402,801 unique GSCII Objects and counting!



The above image illustrates the deeper magnitude limit of the GSC2 compared to the GSC 1.

The Catalogs and Surveys Branch of the Space Telescope Science Institute has been digitizing the photographic Sky survey plates from the [Palomar](#) and [UK Schmidt](#) telescopes to produce the GSC and DSS. These catalogs support ground and space-based telescope operations and provide a valuable scientific resource to the astronomical community.

The Guide Star Catalog II ([GSC II](#)) is an all-sky catalog based on 1" resolution scans of the photographic Sky Survey plates, at two epochs and three bandpasses, from the Palomar and UK Schmidt telescopes ([DSS](#)). With more than 998 million unique objects in the database thus far, construction of the complete GSC-II is still in progress. The GSC2.2 is an all-sky, magnitude-selected subset of the complete catalog designed to support Telescope Operations. It contains positions, classifications, and magnitudes for 435,457,355 objects, and is now [available](#) to the community via the WWW.

The Guide Star Catalog I ([GSC I](#)) is an all-sky optical catalog of positions and magnitudes of approximately 19 million stars and other objects in the 6th to 15th magnitude range. GSC I catalog is used for the control and target acquisition of the Hubble Space Telesope. The GSC I paper by [Lasker et al, 1990](#), was selected as the greatest breaking article in astrometry published during the 1900s, and was included in the AAS Centennial Issue of the Astrophysical Journal.

Getimage	Headers	Real Sky	DSS Coverage	Tools	Availability	Calibrations

In order to support HST operations and provide a service to the astronomical community, CASB has been digitizing the photographic Sky Survey plates from the Palomar and UK Schmidt telescopes. Each plate covers 6.5 x 6.5 degrees of the sky and have been digitized using a modified PDS microdensitometer with a pixel size of either 25 or 15 microns (1.7 or 1.0 arcsec respectively). These images are 14000x14000 (0.4GB) or 23040x23040 pixels (1.1GB) in size and are difficult to access quickly. To provide convenient access to these data, the images have been compressed using a technique based on the H-transform to reduce the data volume. Although the technique is lossy, it is adaptive so that it preserves the signal very well. We typically compress the data by a factor of 7, but much higher compression ratios are possible. These compressed data are then placed on CDROM and placed into a jukebox for rapid access. Users can then easily retrieve image data for any part of the sky. The first epoch images have already been published on CDROM, and the second epoch POSS-II and SES surveys will be distributed widely to the community once they are completed. Currently CDROMs of the prepublication data are only being distributed to a small number of institutions who are supporting the CASB effort to digitize and compress these survey plates.

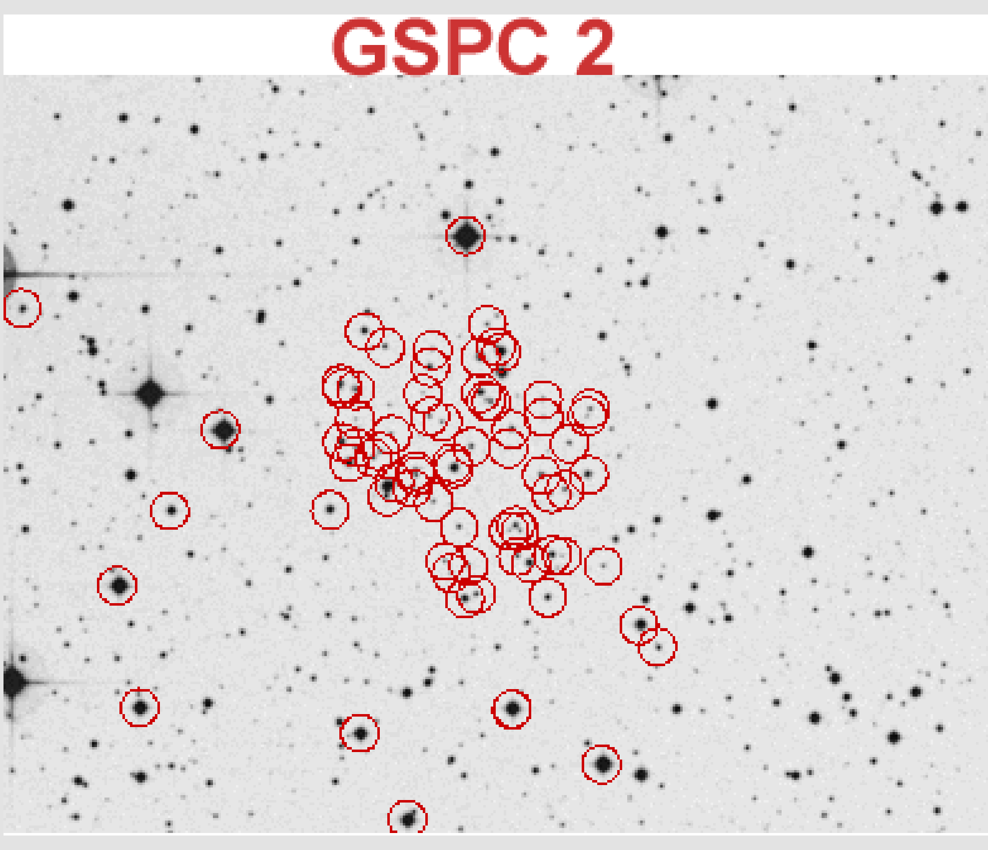
GSPC I	GSPC II	GSPC II Sky Coverage	Data Access

The primary effort of the Catalogs and Surveys Branch of the Space Telescope Science Institute has been the construction of the Guide Star Catalog, both GSC-I and GSC-II. To support photometric calibration of these catalogs, CASB produced the Guide Star Photometric Catalog (GSPC-I) and now in collaboration with Osservatorio Astronomico di Torino are producing its extension GSPC II.



GSPC I is an all-sky set of photoelectrically determined BV sequences in the magnitude range from 9 to 15, generally near the centers of the fields of the GSC-I plates.

GSPC II is generally an extension of GSPC I sequences to V=19 in (B), V and R passbands based on CCD photometry. Its purpose is the calibration of the GSC-II. New northern sequences are being added to support the POSS-II currently in production and the first release (624 sequences) is now available to the public through data access. These sequences represent about one third of the total number of GSPC-II target fields. Our present efforts are focusing on quality control of the remainder of the in-house data, and on (re-)observations of the missing sequences, with the primary goal of publishing photometric calibrators for the entire sky in (B), V, and R passbands.

The Very Large Telescope Project

ESO is building what will be the World's largest optical telescope array, The Very Large Telescope (VLT). The VLT Project organisation is responsible for the design and construction of the Unit Telescopes, including enclosures, optics, adapter-rotators and coating unit. It is based at the ESO Headquarters in Garching, Germany.

The VLT Project

The ESO Very Large Telescope will consist of four 8-meter telescopes which can work independently or in combined mode. In this latter mode the VLT provides the total light collecting power of a 16 meter single telescope, making it the largest optical telescope in the world. The four 8-m telescopes supplemented with 3 auxilliary 1 m telescopes may also be used in interferometric mode providing high angular resolution imaging. The useful wavelength range extends from the near UV up to 25 microns in the infrared.

The Paranal Observatory is located on Cerro Paranal in the Atacama Desert, northern Chile. Science operation with the first unit telscope (UT1) is scheduled for the first half of 1999. Full operations of all telescopes is expected shortly after the turn of the century. The latest news, press releases, and other information material about the VLT can be found in a separate web document.

The following links provide information about the VLT Project, in particular concerning the engineering aspects and the on-going construction activities.

STScI • ACDSD • MAST • CASB

Scanning Machines	Plates	Plate Vault	History	Documentation

CASB maintains an archive of several thousand Schmidt survey plates in a secure, environmentally controlled plate vault. Original plates of the POSS-II and SES surveys pass through our facility for digitization on one of our two GAMMA scanning machines. These machines, which started life in 1983 as standard Perkin-Elmer PDS 2020G microdensitometers, were modified in the early 1990s for multichannel operation. Each can automatically scan an entire Schmidt plate at 1 arcsecond resolution in less than seven hours.

System Requirements	Export Catalog	Architecture	Object Model	Sky Partitioning (HTM)	Status Codes

COMPASS is an object oriented database designed for the production of the second generation Guide Star Catalog (GSC-II). The database project is a collaborative effort between the Space Telescope Science Institute, USA and the Osservatorio Astronomico di Torino, Italy.

It will contain approximately two billion stars, galaxies, and other objects based on measurements of about 6000 sky survey plates. The data consists of:

- Measurements and calibrations of individual astronomical objects up to 5 plates
- Parameters of the individual plates
- Externally produced catalogs with cross-indexing on which the physical calibrations are based on
  - Tycho
  - GSPC2
  - PPM
- Full calibrations of the measured data
  - Positions
  - Brightnesses
  - Colors
  - Proper Motions

The object-oriented schema is built upon the commercial database, Objectivity, using a C++ binding for persistent objects. COMPASS storage hierarchy is based on 32768 sky areas, i.e. region databases, with links to a separate Plate database. The sky tessellation has been selected as part of a proposed community effort to construct a common partitioning of the celestial sphere. The intent of the common partitioning scheme is to ensure large-scale astronomical databases remain as interoperable as possible.

GSC-II 6th Annual Meeting Agenda

October 19-20 2000

CBBC, Stevensville, MD

Meeting Summary	Photographs

Thursday 19th October

08:30 - 09:10 ***Welcome Refreshments***

Introductory

09:10 - 09:15	Fraher	Welcoming Remarks
09:15 - 10:00	McLean	Project Overview
10:00 - 10.15	Lattanzi	Science Overview
10:15 - 10:30	Greene	Database Overview
10:30 - 11:00	***Coffee Break***	

Production Management

11:00 - 11:20	Loomis/Sturch	Plate Processing Status
11:20 - 11:40	Morrison	Plate Calibration Status
11:40 - 12:00	Wolfe	Infrastructure – HSM/DB Backups/DSS
12:00 - 14:00	***Lunch***	
13:30	Conference photo and	Great Chesapeake Bay Schooner Race
		Schooner FAREWELL (Cpt.Meakes)

Astronomical Tasks

14:00 - 14:20	Morrison	Astrometry
14:20 - 14:40	Garcia	Photometry
14:40 - 15:10	Laidler	Classification
15:10 - 15:30	Bucciarelli/Garcia	GSPC-II Status
15:30 - 16:00	***Coffee Break***	

Quality Control

16:00 - 16:15	Lattanzi	OATo Global QA

Catalog Properties	GSC 2.2 Release Notes	Background	Plate Material
Image Processing	Calibrations	Science	Data Access

998,402,801 unique GSCII Objects and counting!

The GSC II is an all-sky catalog based on 1" resolution scans of the photographic Sky Survey plates, at two epochs and three bandpasses, from the Palomar and UK Schmidt telescopes (DSS). Positions, magnitudes, and classifications are produced for all objects on each plate. The objects are then loaded into the COMPASS database, where multiple observations of the same object are matched and assigned a unique name based on the HTM sky tesselation that has become a community standard. This provides the multi-wavelength, multi-epoch data necessary to produce colors and proper motions.

Construction of the complete GSC-II is still in progress. More than 998 million unique objects have been loaded into the COMPASS database thus far, based on plate-limited image processing and calibrations for all sky survey plates in two bandpasses (J and F) in both hemispheres. Processing of the near infrared plates and the POSS-I plates in the north is still ongoing.

The GSC2.2 is an allsky, magnitude-selected subset of this data that has been extracted to support telescope operations at the GEMINI and VLT telescopes. As of July 16, 2001, this Telescope Operations version 2.2.01 contains positions, classifications, and magnitudes for 455,851,237 objects, and is now available to the community via the WWW. The magnitude limits (18.5 in photographic F or 19.5 in photographic J) were implemented to ensure the photometric quality of the released data. Since bright objects are extremely overexposed on the Schmidt plates, we have replaced these bright objects with those from the Tycho-2 catalog. Please read the release notes for additional details on the GSC2.2, and check the catalog properties page to see how it updates and extends its predecessor, the GSC I.

The final version (GSC 2.3), expected to be released in 2002, will also contain proper motions.

The catalog will be used for operational support of HST, the GEMINI telescopes, ESO's Very Large Telescope (VLT) as well as future space missions such as the Next Generation Space Telescope (NGST).

Please note that GSC 2.2.01 is 40GB in size and that we do not have the resources to support downloads or make copies of the entire catalog for individual researchers or institutions at this time - only participating institutions. We are looking at options and costs for a mass distribution of GSC 2.3 on some media. The major data centers and observatories which contributed to the production of this catalog are also providing on-line access to the world-wide community.

Please read the fine print:

data copyrights • data use policy • data acknowledgements

The Guide Star Catalogue II is being constructed by the Catalogs and Surveys Branch of the Space Telescope Science Institute and the Osservatorio Astronomico di Torino in collaboration withthe Astrophysics division of ESA, the GEMINI project and the ST-ECF .

Dr. Barry Lasker was the most important single individual in the development of the Guide Star Catalogue and Digitized Sky Survey projects. He originated the concept of building a Guide Star Catalog to support guide star selection for HST. In the 1980s, he led the team that customized the Perkin-Elmer 2020G microdensitometers to bring them up to the positional and photometric accuracy standards required for the GSC I, and in the 1990s, he led the team that redesigned them entirely to permit rapid scanning of the second epoch surveys, at even finer resolution, for the GSC II. He was awarded the 1998 Van Biesbroeck Prize, which recognizes extraordinary service to the astronomical community, in recognition of his leadership and innovation in the production and distribution of the Digitized Sky Survey. He developed the international collaborations which have supported these projects. His creative scientific leadership of the GSC and DSS teams through the years was rivalled only by the generous friendship he shared with us all.

Barry's sudden passing, in February 1999, was a shock and a deep loss to all who knew him. We in the Catalogs & Surveys Branch were hit especially hard. The GSC2 project was still years from completion, and Barry was still deeply involved in almost every aspect of it. Somehow, we had to continue the work without his key insights and unfailing intuition (not to mention his uncanny knack with the scanning machines). It was a daunting prospect. But we were determined. Many of us said, in the first days after his death, that we were determined to do it *for* Barry: to pull it off somehow, to complete the grand project that was so much of his life's work.

Well, we're not finished yet. But the public release of GSC2.2 is a significant milestone, and we could not let it go public without talking about Barry.

Under the effective leadership of Dr. Brian McLean, who accepted the challenge of managing the group after Barry's death, we have completed a great deal of what, in 1999, was still to be done. The end of the project is clearly in sight.

And so at this time, we would like to say,

Barry,

These 435,457,355 catalog objects

are for you.

Vicki Laidler
on behalf of the entire GSC2 team

Guide Star Catalog I

Last Updated Jan 2001

"The GSC and the Digital Sky Survey (DSS), from which the GSC is derived, have transformed astrometry from an 'art form' practiced by a few professionals to a tool utilized by an ever-increasing number of astronomers, professionals and amateurs alike." - Dr. W. F. van Altena, ApJ 525:1283, Centennial Issue

The Catalogs and Surveys Branch of the Space Telescope Science Institute constructed the Guide Star Catalog I (GSC I) to support the pointing and target acquisition for the Hubble Space Telescope. For the last decade the GSC I has been used for numerous other purposes, for example, the observation planning for fiber optic spectrographs, the preparation of finding charts, and the operation of ground-based telescopes.

The GSC I catalog is an all-sky catalog of positions and magnitudes for approximately 19 million stars and other objects in the sixth to fifteenth magnitude range. The GSC is primarily based on an all-sky, single-epoch collection of Schmidt plates. For centers at +6° and north, a 1982 epoch "Quick V" survey was obtained from the Palomar Observatory, while for southern fields, materials from the UK SERC J survey (epoch = 1975) and its equatorial extension (epoch = 1982) were used. See plate material for more information on the plates.

All the plates were digitized at the Space Telescope Science Institute into 14000 X 14000 rasters at a 25 micron sampling interval using two modified PDS micro-densitometers. For more information on the plate processing consult Lasker et al., 1990, AJ, Vol 99, 6. This paper was selected as the groundbreaking article in astrometry published during the twentieth century, and was included in the AAS Centennial Issue of the Astrophysical Journal.

The GSC 1.1 is used for control and target acquistion of the Hubble Space Telescope.

The GSC 1.2 is an astrometric recalibration of the GSC 1.1, and should not be used for HST operations.

Please read the fine print:

The Guide Star Photometric Catalog (GSPC-I) is an all-sky set of 1477 photo-electrically determined BV sequences covering the magnitude range from 9 to 15. The GSPC was created to provide photometric calibrators for the Guide Star Catalog (GSC-I), which is a catalog of approximately 19 million stars and objects classified as non-stars needed to support the pointing of the Hubble Space Telescope.

GSPC-I sequences nominally contain (at least) six stars, each with a photometric precision of 0.05 mag. In practice, a small number of sequences contains fewer stars, and the precisions achieved for the faintest stars are more nearly 0.1 mag.

For more information about GSPC-I, go to the paper by Lasker, Sturch, et al., Ap. J. Supplement, Vol. 68, 1988 .

To view data from an enhanced version of GSPC-I, go to the ADC catalog.

Guide Star Photometric Catalog II

Last Updated Jan 2001

The Guide Star Photometric Catalog-II (GSPC-II) is being created by the STScI Catalogs and Survey Branch and the Osservatorio Astronomico di Torino (OATo) to provide photometric calibrators for the Guide Star Catalog-II (GSC-II). Most of the GSPC-II star sequences extend the GSPC-I sequences to a limiting magnitude of V = 19 or fainter based on CCD data in the V and R bandpasses of the Johnson-Kron-Cousins system. Where resources were available, which is for a large part of the southern hemisphere and for a few northern fields, a B band was also included, and the limiting magnitude brought to ~20. While the southern second-epoch plates used for GSC-II lie on the same 5 deg grid pattern used for for GSC-I and require no additional sequences, the northern POSS-II plates supporting GSC-II lie on a similar 5 deg grid which differs from the 6 deg grid used for GSC-I. This results in a number of POSS II plates being considerably shifted with respect to the original grid, and therefore poorly covered by the GSPC-I sequences. New northern sequences are being added in GSPC-II to support calibration of such POSS-II plates.

The observations were obtained with mostly one-meter class telescopes at ten observatories. Most of the northern GSPC-II sequences were imaged at the Kitt Peak and Wise Observatories, whereas southern declinations were covered by Cerro Tololo and ESO-La Silla observations. Data also were acquired at Mt. Hopkins, Mt. Laguna, Lowell, Mt. Megantic, McDonald and JKT La Palma observatories. The observation strategy was to take CCD frames centered on the faintest star of the corresponding GSPC-I sequence where one was available. When necessary, both long (~8-15 min) and short (<3 min) exposures were acquired in each field. Short exposures times were chosen to be appropriate for the typical 14.5 mag target star. For new POSS-II fields lacking GSPC-I sequences, the telescope was pointed to the nominal center of the corresponding survey plate, and the pointing adjusted to avoid bright stars.

For more information see: the journal article: "An All Sky Set of (B)- V-R Photometric Calibrators for Schmidt Surveys: GSPC2.1: First Release", Bucciarelli, et al. A&A 368, pp 335-346, 2001

IUEDR-IUE Satellite Data Reduction Package

This system provides documentation, help and news for users of the IUE Satellite data reduction package IUEDR. The current page is an overview of the system and a summary of how to use it. There is a (slightly out of date) **imagemap** version of the menu list below.

Highlighted items indicate a reference to another page. To display that page simply click on the item.

iuedr Use the `iuedr` symbol to get back to this page at any point.

This is an "experimental" service. Feedback via WWW or e-mail to *mjc@star.ucl.ac.uk* are invited. All comments are welcome.

What's Available?

Here are the sub-topics covered by this system:

- **Support for IUEDR limited**
  Starlink support for IUEDR is already at the minimum level - no time is available for enhancements. It is expected that Starlink support for IUEDR will cease at the end of 1999.
- **What's new in the IUEDR pages**
  Recent changes and additions to these web pages.
- **Accessing NEWSIPS FITS files**
  Simple tools to access the NEWSIPS LORES products.
- **A data reduction tutorial**
  Based on Richard Tweedy's 'IUEDR data anlysis Tutorial'.
  Gets anyone started on realscience.
- **Help!**
  The Online HELP system pages for WWW.
- **IUEDR Web pages index**
  Search the IUEDR pages for a word.
- **Documentation**
  All the IUEDR documentation and more.
- **Data Reduction Cookies**
  Some scripts for processing multiple IUEDR datasets.
- **NASA IUE Merged Observing Log** / **STADAT IUE Account**
  On-line searchable versions of the IUE log.
- **NASA Archive Form** and **RAL Archive Pages** / **Directories**
  Access to the NDADSA and RAL IUE databases.
  You may be able to extract the datasets you need from here.
- **VILSPA/IUE homepage**
  Information about the spacecraft maintained at VILSPA.
  Newsletters and data on the IUEFA can also be found here.
- **NASA/IUE homepage**
  Information about the spacecraft maintained by NASA.
- **Comments** and **Bugs**
  A chance to report bugs and make comments and suggestions on IUEDR.
- **New features in IUEDR Vn. 3.2-0**
  What's new in the current release.
- **There is no beta release**
  Because the released version (3.2-0) is up to date!

About NEWSIPS data handling

Introduction

Data processed with NEWSIPS are stored in FITS format and comprise:

- For Low Resolution Data:
  - raw image (`RILO` extension),
  - linearized image (`LILO` extension),
  - resampled spectral image (`SILO` extension) and
  - extracted and calibrated spectrum (`MXLO` extension).
- For High Resolution Data:
  - raw image (`RIHI` extension),
  - linearized image (`LIHI` extension),
  - resampled spectral image (`SIHI` extension) and
  - extracted and calibrated spectrum (`MXHI` extension).

Note: only resampled low dispersion images (`SILO`) and extracted and calibrated spectra (`MXLO,MXHI`) will be provided at the VILSPA NEWSIPS Data Server.

Reduction packages

NEWSIPS data can be analysed under MIDAS and IDL.

- **MIDAS** requires the **IUE context**, available at ftp://iuearc.vilspa.esa.es/pub/iuemidas/. MIDAS works under Ultrix (version 4.4) and VMS (version 6.2).
- **IDL** can be used with the IUERDAF package running on version 2.0 or higher. IUERDAF works in ULTRIX, SUN-UNIX, SOLARIS, Vax VMS or Windows. This package is available at ftp://iuewww.gsfc.nasa.gov/pub/software/
- FITS data produced by NEWSIPS can also be read by other packages, like the FITSIO and FTOOLS software of HEASARC or several other IDL FITS readers like READFITS + TBGET, FXBOPEN + FXBREAD or MRDFITS from the ASTRON library, and IFITSRD or READMX from the IUEDAC library

---

How to use the IUE context in MIDAS

This context is enabled with the command `set/context IUE` (see the on-line help for a more detailed explanation of the commands available under this contex). Examples of how to read and convert NEWSIPS low resolution and high resolution data in MIDAS format from disk and tape are briefly summarized below.

• Low Resolution Data

Example: How to read and work with the 1-D NEWSIPS Low Resolution spectrum (.MXLO)

```
convert/mxlo SWP32192 (without extension)
```

The command will create a MIDAS table with the extracted spectra as SWP32192L.tbl (for large aperture) and/or SWP32192S.tbl (for small aperture). The tables have the following columns:

```
 Col.    1:WAVELENGTH       Unit:ANGSTROM         Format:F10.3  R*8
 Col.    2:NET              Unit:FN               Format:E15.5  R*4
 Col.    3:BACKGROUND       Unit:FN               Format:E15.5  R*4
 Col.    4:SIGMA            Unit:ERG/CM2/S/A      Format:E15.5  R*4
 Col.    5:QUALITY          Unit:                 Format:I11    I*2
 Col.    6:FLUX             Unit:ERG/CM2/S/A      Format:E15.5  R*4
```

The comamnd `plot/mxlo` plots low dispersion NEWSIPS spectra in MIDAS table format. Three options are available as

```
PLOT/MXLO SWP32192L F     To plot flux and sigma spectra
PLOT/MXLO SWP32192L G     To plot gross, flags and background spectra
PLOT/MXLO SWP32192L N     To plot net and quality spectra
```

Example: How to read the NEWSIPS reduced files (.RILO/.LILO/.SILO)

`indisk/fits SWP32192.`*`EXT`* `SWP32192`

Where *.EXT* is the extension .RILO, .LILO or .SILO. This command converts FITS format on disk to standard MIDAS (`.bdf`) format creating the image `SWP32192.bdf` which allows you to use the standard MIDAS commands for images handling.

• High Resolution Data

(under construction)

How to use IUERDAF for IUE data

Examples: How to read 1-D NEWSIPS spectra (.MXLO/.MXHI)

For a single aperture low dispersion image:
`readmx,'swp32525.mxlo',main,wave,flux,flags,sigma,bkgrd,net`

To read the region of a high dispersion spectrum containing Mg II:
`readmx,'lwp12345.mxhi',h,w,f,q,s,wrange=[2790,2810]`

To output all extracted points for high dispersion order 100:
`readmx,'lwp12345.mxhi',h,w,f,q,s,orange=100`

The command `readmx` reads the IUE merged extracted spectra FITS file (.MXLO/.MXHI) and returns the header, wavelength, absolute flux, flags, sigma, background and net flux as IDL variables.

Example: How to read NEWSIPS raw images (.RILO/.RIHI)

`readri,'SWP32525.RILO',main,image`

This command reads IUE raw image FITS files and returns the primary FITS keywords, vicar label, history portion of the FITS header, and image as IDL variables.

Example: How to read NEWSIPS linearized images (.LILO/.LIHI)

`readli,'SWP32525.LILO',main,image,flags`

This command reads IUE linearized image FITS files and returns the primary FITS keywords, vicar label, history portion of the FITS header, image and NEWSIPS flags as IDL variables.

Example: How to read NEWSIPS resampled files (.SILO/.SIHI)

For a low dispersion image:
`readsi,'SWP32525.SILO',main,wave,image,flags`

For a high dispersion image:
`readsi,'SWP32525.SIHI',main,wave,image,flags,cri`

the wavelength vector for the first order in the SIHI file is:
`w1=wave(0,0)+wave(1,0)*findgen(768)`

The command `readsi` reads IUE resampled image FITS files and returns the header, wavelength, image and flags as IDL variables.

Handling flux calibration and sensitivity degradation files

When working with SILO files, for instance to reprocess spectra of extended objects, you need to fully calibrate the extracted spectrum. Inverse sensitivity functions as well as correction factors for both SWP and LWP cameras are available at ftp://iuearc.vilspa.esa.es/pub/calib/ . You are referred to the NEWSIPS Manual for information on absolute calibration derivation and on the application of time and temperature dependent sensitivity corrections.

Information related to NEWSIPS and IUE Final Archive Project

Newsips Processing Manual and general information about the Final Archive project are available on the WWW.

E. Solano, D. de Martino and N. Loiseau

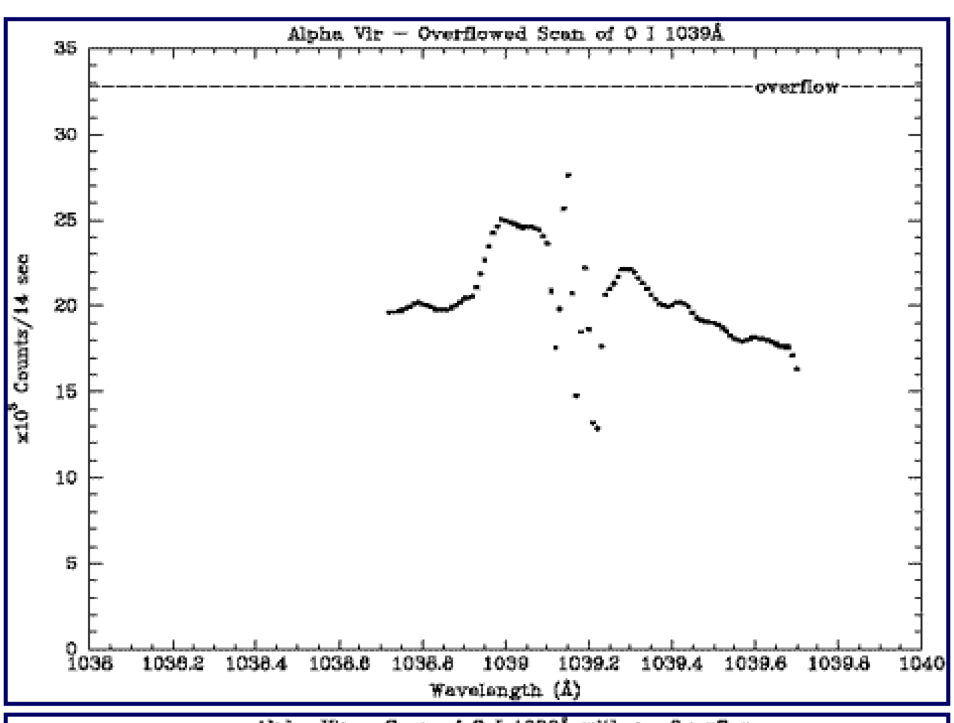
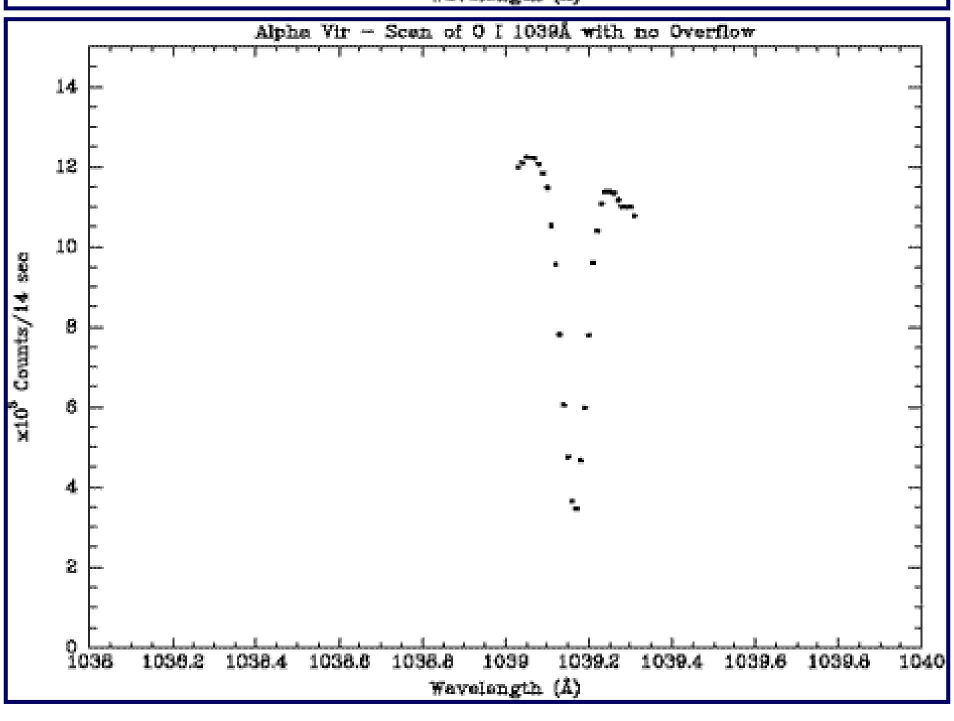
Last updated: Jul 7, 1999

Common Data Problems

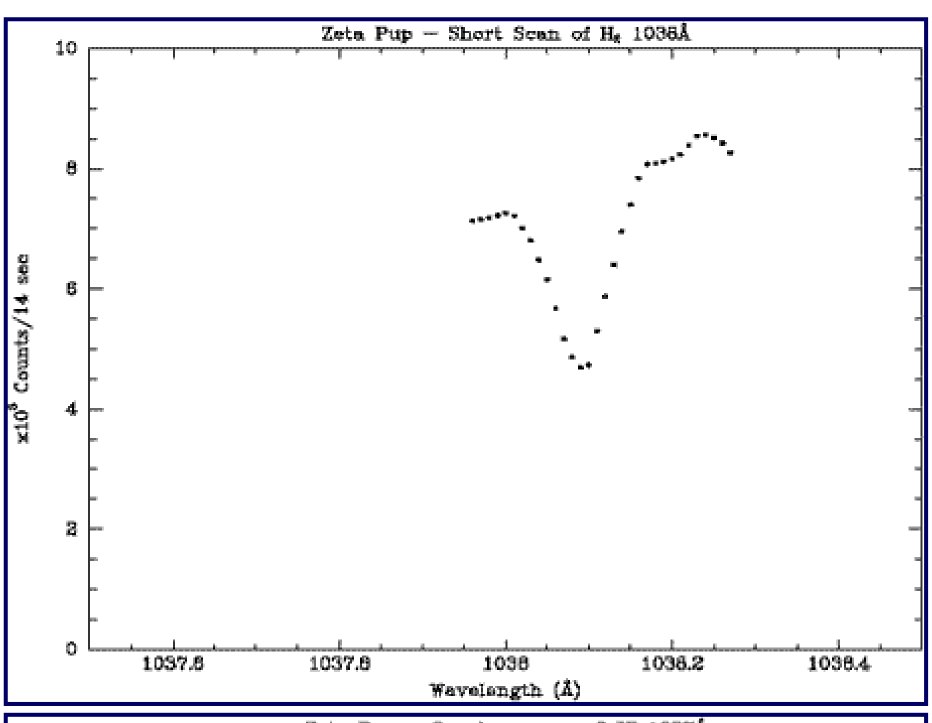
Data taken with the *Copernicus* spectrometer is usually quite easy to deal with after determining the background, however there are still a number of things that could go wrong that one has to watch out for when dealing with these datasets. **It is particularly important when using Copernicus data to look at the individual scans as well as the final stacked scan to be sure you do not miss any drifts, glitches, overflows, etc that can distort the final stacked output**. Some (but by no means all) of the problems that can occur in *Copernicus* data are shown in the examples that follow, as well as some suggestions for how to spot these problems.

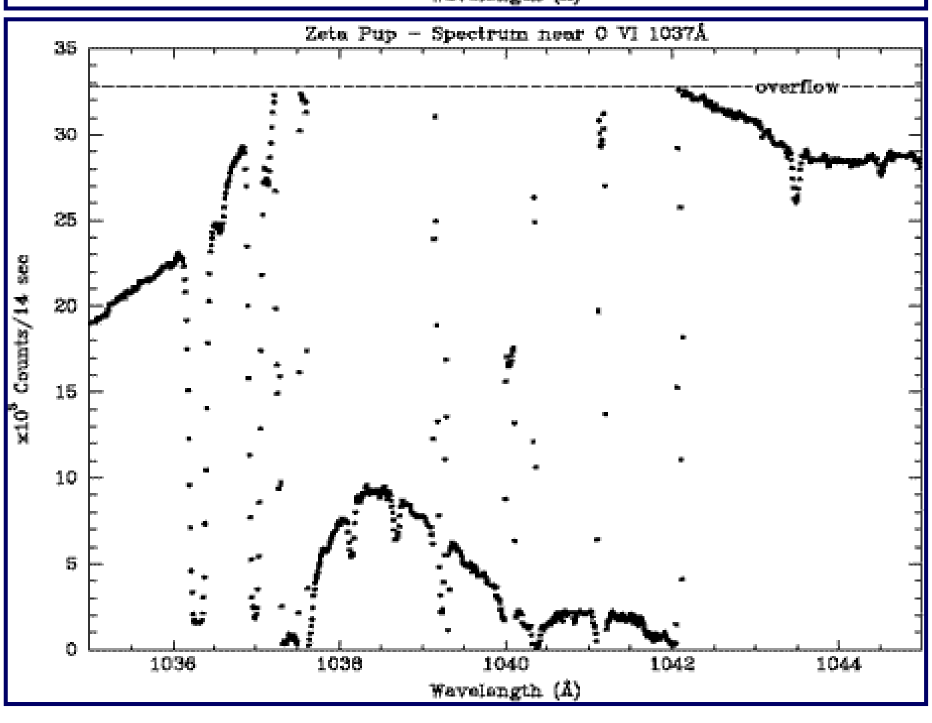
At the beginning of the mission the sensitivity of the instrument was quite high, occasionally the number of counts recorded during a scan exceeded the number of counts that could fit in the data buffer (32,767 counts in 14 seconds), when this occurred the counts "wrapped around" and restarted at zero. This can be most easily seen by comparing two scans of the same spectral region, the following figures show two scans of the O I line at 1039Å line towards the star alpha Vir, the first shows a scan where the continuum has overflowed the data buffer, and the second a scan taken at a later date when the instrument sensitivity had declined --





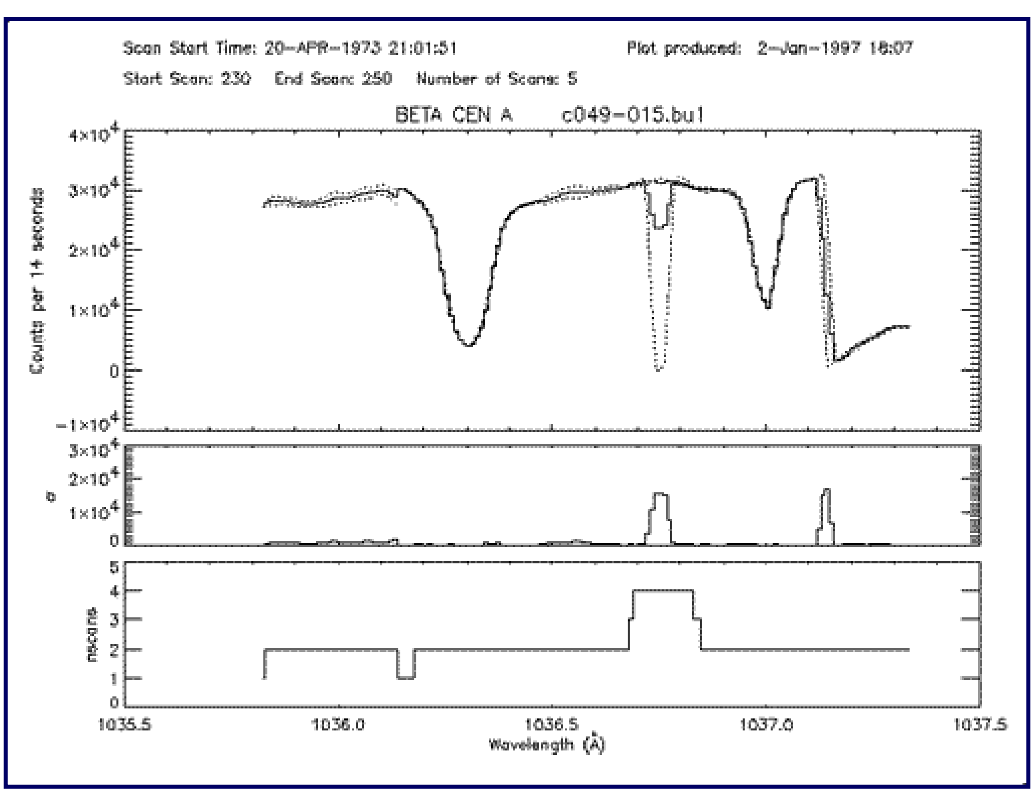
Since scans of single lines usually included only a small range of wavelengths (and thus sampled only a short section of the continuum) it can often be difficult to determine when an overflow has occurred. Since strong lines will be near zero in their cores and thus can only overflow in the wings of the line and in the continuum, one can find the approximate wavelength range over which overflows are likely to have occurred. The following two figures show a case where a scan of a (relatively weak) line does not provide enough information to identify this wavelength interval as one where the data registers overflowed, the continuous scan taken at roughly the same time shows that this data is in fact overflowed:





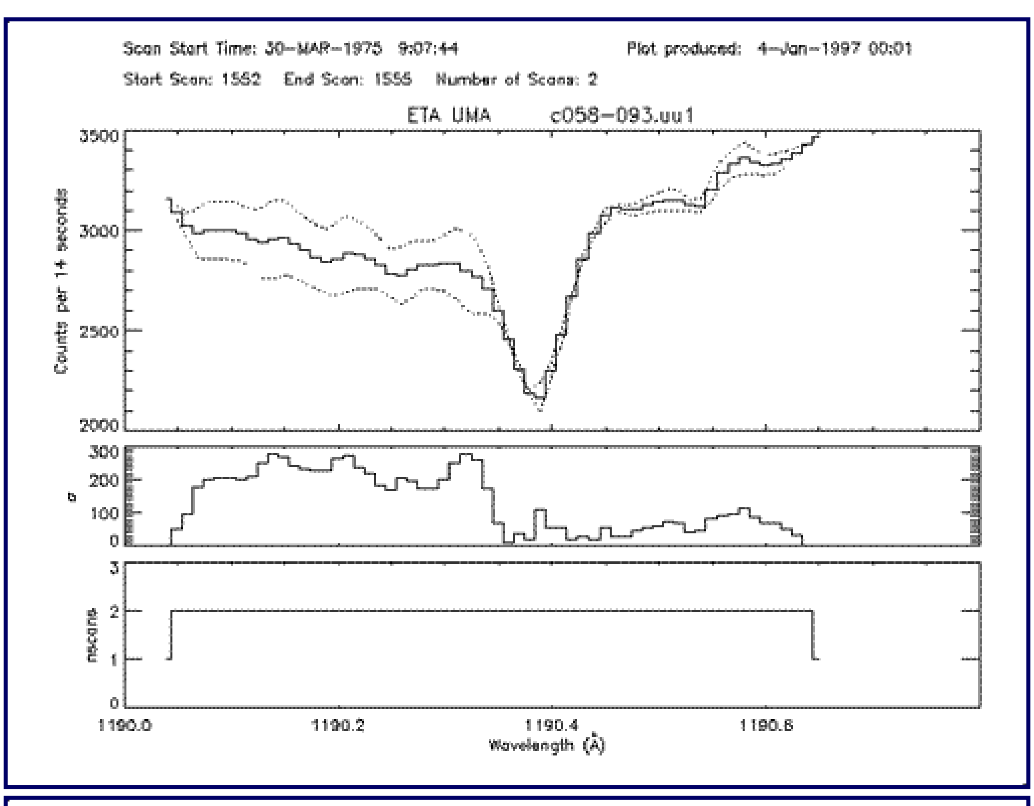
The correction for an overflow where only a section of the data in a stacked scan has overflowed (especially where the transition occurs within a line of interest) is in generally not possible unless the entire region of interest has overflowed. In cases (such as the scans of the 1039Å line towards alpha Vir) where the transition occurs in the middle of the region of interest one must go back to the raw (and thus un-interpolated) data, correct the overflow by adding 32767 counts to the appropriate fluxes, and then re-stack the data.

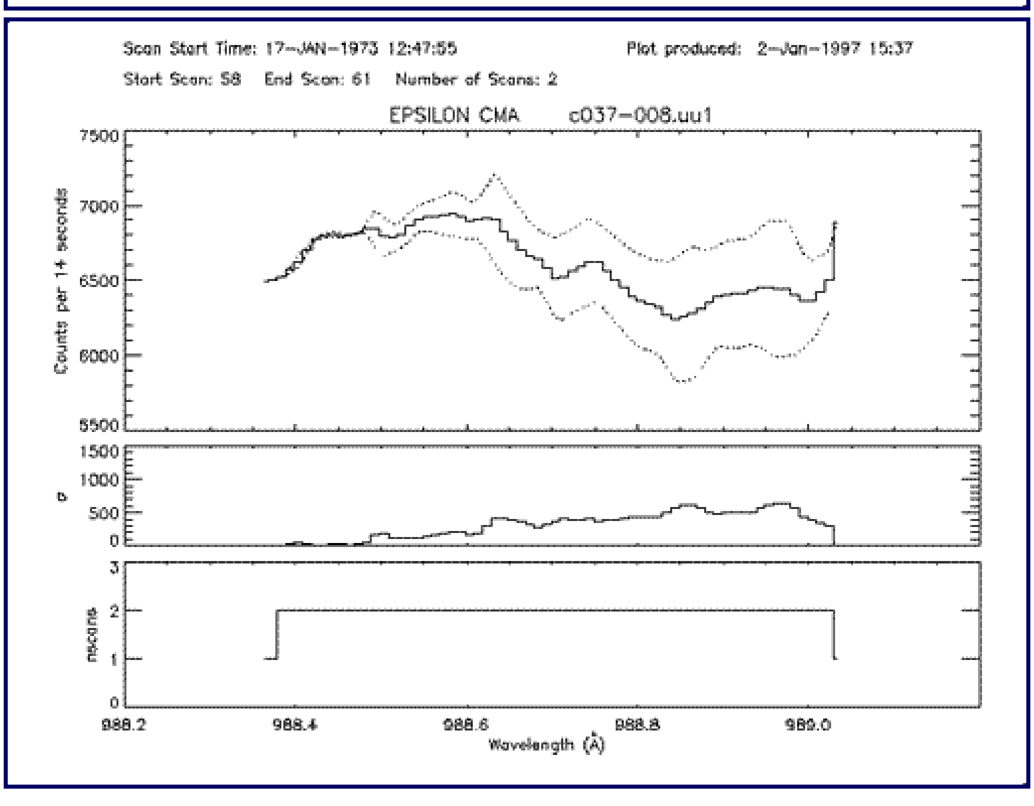
One must be very careful to check the individual scans for overflows whenever the countrate is near 32,000 counts per 14-second. Overflows of single wavelength points can occur in one or two of a group of scans and create a **false line** as is shown here:



Besides overflows there are also spurious decreases and/or increases in the countrates in some scans. The most likely cause of a decrease in the countrate is pointing error, while increases in the countrate are generally caused by a rise in the particle background (see below). In general such changes are not caused by variations in the amount of stray light being blocked by to carriage-2, although this can only be ruled out by a point-by-point comparison of the U1/V1 and U2/V2 positions with **Figure 9** of the Guest Investigators Guide.

The spacecraft pointing accuracy was generally about 0.02 arc seconds during the typical single scan of spectral lines, this was good enough so that the counts are usually not noticeably affected by guidance changes. However, occasionally the spacecraft drifted, which results in a sudden and often temporary drop in the count rate during a scan. These figures show examples of apparent tracking errors, note the large variation in the net flux between scans:





Occasionally one sees sudden **increases** in the count rate during a series of scans of a single line. Such changes are generally attributable to a rise in the particle background. While observations were generally planned so as to avoid the South Atlantic Anomaly (SAA) where the particle background is large, occasionally the edges (which were not that well defined) of the SAA were crossed. There are also a few observations that were taken during a crossing of the SAA itself, such scans are characterized by a larger than usual background (listed in the TBACK column of the raw data). **Figure 6** of the Guest Investigators Guide shows the typical variation in particle background within an orbit.

Photometric Reductions

The following section on photometric reductions was reprinted, with permission from the author, from the paper "The Copernicus Ultraviolet Spectral Atlas of Tau Scorpii" by John Rogerson and Walter Upson (Ap J Suppl. 35,37-110,1977). The corrections described for cosmic ray and charged particle background, guidance variations and scattered light however, are relevant to all Copernicus observations.

The variation of the instrument sensitivity with wavelength is not well known, and consequently no attempt has been made to normalize the observations to a constant sensitivity condition. This atlas should therefore not be used to estimate the general shape of the ultrtaviolet continuum of Tau Sco, but it is entirely suitable for investigation of the line spectrum.

The counts detected at each measurement point reflect the flux in the stellar spectrum but are also affected

1. by a background due to cosmic rays and trapped ions from the lower Van Allen belt,
2. by how well the guidance system keeps the star image centered on the spectrometer entrance slit, and
3. by scattered light within the spectrometer.

Corrections for these three effects are considered below. The counts may also be affected by the strength and direction of the magnetic field in which the photomultiplers find themselves, but the behavior of many repeated U2 counts at a fixed point in the spectrum suggests that this effect must be small. This is presumably also true for U1, which is physically identical and operated identically.

Cosmic Rays and Charged Particles

This source of background counts has been carefully studied by York and Miller (1974) using counts obtained when starlight was not entering the spectrometer. The cosmic ray flux depends mainly on the geomagnetic lattitude of the satellite, while the trapped particles are primarily concentrated in the South Atlantic Anomaly. In addition, some of the data photomultipliers have windows the fluoresce for some time following a heavy exposure to the charged particles, with the result that the background for these tubes at a particular time depends not only on the current particle flux but also on their recent exposure. Although the data for this atlas do not depend on these fluorescing tubes, the background counts for all tubes are estimated by the same procedure. Under these circumstances it is expedient to designate the position of the satellite by the longitude of the ascending node of the orbit and the time after pasage of the satellite through this node. Using this coordinate system ensures that each time the satellite reaches a certain coordinate pair, it will have had the same recent history of cosmic ray and trapped particle flux exposure. The study by York and Miller shows that the background counts are quite repeatable (within expected statistical flucuations) over time intervals that are long compared to the Tau Sco observing interval when using the above-described coordinate system. Aimed with this empirical result, a table was prepared giving the expected background count as a function of the satellite coordinates, and this table was then used in removing the background count from each measurement.

[***Note: the Copernicus raw data files include background counts for most scans (see precautionary comments though). In cases where a background was for one reason or another not included, a program is available for deriving values as described above. Also, the table of background counts as a function of coordinates, is now available in FITS format.***]

Correcting for Guidance Variations

In spite of an excellant guidance system, changing external torques operating on the satellite cause the stellar image to drift about on the entrace slit of the spectrometer. The result is that the amount of stellar flux entering the spectrometer slowly changes, giving rise to variations in the observed spectrum which have no counterpart in the star's intrinsic spectrum. These variations may be as great as 10%. This effect can be corrected with the help of the signal from U2 which, as noted before, is held fixed so that its output signal provides information on the variation of stellar flux entering the spectrometer. Each U1 count is corrected for guidance drift by dividing it by the simultaneously acquired U2 count and multiplying it by the average of all U2 measurements made with U2 held fixed in position.

While the correction procedure is straightforward in theory, there are four operations that must be performed on the U2 counts before they can be used to correct for guidance variations. First, the cosmic ray and charged particle background must be removed. This is accomplished in the same manner as described above for U1. Second, while U2 is help fixed in the spectrometer, its wavelength is not quite fixed in the stars spectrum. This is caused by the changing Doppler shift mainly due to the orbital motion of the satellite. The componenet of the satellite velocity in the direction of the star is known for each measurement, and hence the instantaneous wavelength being observed by U2 can be calculated. In order to predict the U2 count variations due to the changing wavelength, the U1 spectrum in the neighborhood of the U2 position has been numerically degraded to the U2 spectral resolution (nominally 0.2 Å). This degraded U1 spectrum gives the local spectral variation of the U2 signal and allows the U2 counts to be corrected to what they would have been in the absense of a variable Doppler shift. The correction is generally quite small since the satellite valocity range of ± 7.5 km/sec is small compared to the U2 resolution of about 50 km/sec. Nevertheless, in a few monitoring positions the U2 slit was unintentionally fixed near the edge of a strong absorption feature, and the deduced corrections are not negligble. Third, the corrected U2 signal still contains a noise component which is mainly statistical. Since the guidance variations have a slow time scale (that of the satellite orbital period), we have smoothed the high frequency noise in the U2 signal, leaving intact the low-frequency guidance-induced variations. Fourth, a possible systematic error exists in the guidance correction procedure. The average U2 values for each monitoring position do not necessarily reflect the average quality of guidance; i.e., the total stellar flux passing the entrance slit, averaged over the time interval that U2 is in one monitoring position, may differ from that at another monitoring position. In order to fit together the various spectral segments, the averaged U2 signals must be corrected for variations in average guideance quality at each fixed position.

This correction was made by forming the ratio of U2 signals (corrected as above) near spacecraft midnight for consecutive U2 positions. This ratio ia assumed to be the correct intrinsic ratio since it is measured under approximately the same orbital configuration during a time (midnight) when guidance perturbations due to scattered light are at a minimum. This ratio was then used to correct the average U2 signals to the same quality of guidance.

The corrected and smoothed U2 signal finally was used to monitor and remove the guidance variations in the U1 signal. The separate segments then formed one continuous spectrum.

[***Note: listing files are available which indicate the U1 and U2 scans for which separate monitoring scans were obtained.***]

Scattered Light

Finally, the U1 counts must be corrected for scattered light within the spectrometer. This component of the observed counts may be estimated with the help of a number of interstellar absorption features which appear to be saturated. The residual signal in the saturated core is assumed to be due only to scattered light at the wavelength of the feature. The interstellar features that have been used for the scattered light analysis of the second-order spectrum are listed in **Table 2**.

While studing interstellar absorption at Lyman Alpha, Bohlin (1975) found the U1 scattered light to be linearly proportional to the strength of the local spectrum averaged over a 24 Å band centered on the wavelength of interest. Scattered light values, predicted according to Bohlin's method, were compared with the observed values given in Table 2 and while the dependence on the local average is quite evident, the detailed agreement was of inadequate quality for the purposes of this atlas. Attempts to modify Bohlins formulation to improve the detailed agreement over the whole second-order spectrum were only partially successful, though it was found that an 18 Å average is somewhat superior to the 24 Å average. *See paper for rest of discussion on scattered light.*

Observation Time Correction

We have duplicated (to the second!) the observation times listed in early computer printouts produced by Copernicus principal investigators by adding the first SET time to the GMT observation times listed in the raw and coadded scan data files. The feeling is that our listed observation times refer to the time the Copernicus satellite crosses the longitude of the ascending node (i.e., LAN). It is still unclear however whether this reference time refers to the orbit in which the observation was made or to the orbit in which the data was last dumped.

In any event, the actual calculations for deriving the start and end observation times (from the IDL program coptime.pro), which are based on data extracted from the Copernicus raw data files, are as follows:

```
ddate = (yr_obs-1900)*1.0D+03                ; decimal date
      + day_obs + (hr_obs/24.0D0)
      + (min_obs/(24.0*6.0D01))
      + (sec_obs/(24.0*3.6D03))
fst = (frst_set * 15.72887)/(24.0*3.6D03)  ; first SET time in days
lst = (last_set * 15.72887)/(24.0*3.6D03)  ; last SET time in days
startobs = ddate(i)+fst(i)                 ; start time
endobs = ddate(i)+lst(i)                   ; end time
```

The SET times mentioned above refer to Spacecraft Equivalent Time (SET) and represent units of 15.72887 seconds.

Data Reduction/Analysis

- Analyzing Individual Scans - Examples of analyzing raw data scans.

    2. Stray Light in PEP, II - 15 December 1972
    3. Scattered Light in U1 - 2 March 1973
    4. Background in *Copernicus* Data Tubes - 9 December 1974
    5. U1 Instrumental Profile - 11 April 1975
    6. Corrections to the U2 Wavelength Scale Between 1026 and 1110Å - 7 January 1976
    7. Spurious Emission Line Detection - 12 January 1976
    8. Sensitivity Loss in *Copernicus* - 8 September 1982
- Background Issues - a look at the sources of background counts in scans.
- Common Data Problems - including data register overflow, changes in the particle background (South Atlantic Anomaly), tracking errors, and other glitches.
- Photometric Reductions - describes the photometric corrections used for the Copernicus Spectral Atlases by Rogerson, et al. including a discussion on correcting for guidance variations.
- Observation Time Correction - describes the algorithm used to duplicate the start and end observation times found listed in old Copernicus computer printouts.

III. Description of the Princeton Experiment

A. The spacecraft

The satellite is similar to OAO-2 (described by Code et al. 1979), with some modifications designed to improve the guidance sensitivity when the spacecraft is in daylight, and the pointing stability. The Princeton equipment is described by Rogerson (1963) and Rogerson et al. (1973).

In brief, the Princeton Experiment Package (PEP) consists of a cassegrain telescope with an 80 cm primary mirror, a 7.5 cm secondary, and a Paschen-Runge spectrometer which utilizes a concave grating to focus the spectrum on a 1 meter Rowland circle (see Figure 1). Two movable carriages, each equipped with two photomultiplier tubes, scan the spectrum. These carriages, which are programmed to operate independently of each other, cover the wavelength regions shown in Table 1. The nominal bandpasses are also indicated. For brighter stars, the important region from 1500 to 1560 Å can be scanned with U1 in the first order.

B. Spacecraft pointing

The field of view utilized by the guidance Fine Error Sensor (FES) is 8 minutes of arc in diameter. The FES acts to keep the center of light in this field on the slit; therefore the target star should have no companion less than two magnitudes fainter within 5 minutes of arc.

If this restriction is relaxed, the main image will not be centered in the slit, and the photon count will be reduced accordingly. In the case of very bright sources for magnitude differences only slightly less than two, this loss of signal may be acceptable.

When the line joining the two stars is parallel to the slit, as will happen at short intervals during the year, the main image will be correctly centered, and if the distance between the stars is less than 30 arc seconds, light from both stars will go down the slit. Although it is feasible to command small spacecraft rolls to accomplish this alignment at other times, such maneuvers are generally avoided because of possible risks to the satellite. Several close systems have been observed in this way, including Alpha Cru AB and Sirius AB.

It is possible to introduce a small bias voltage in the FES, so that the center of light of the guidance field of view is as much as 5 arc sec off of the slit. This technique has been used successfully to center one component of a binary (Rho Oph A) on the slit, in a case where the magnitude difference was less than 0.5. Other special techniques have been applied to facilitate observations of stars in crowded fields.

The Inertial Reference Unit (IRU) can be used to point the telescope-spectrometer to within roughly ±40" of a given position on the sky, if a nearby bright star is available which can be used to update the FES. Use of the IRU appears to be a feasible technique for pointing at extended sources such as nebulae. It appears, however, that high-excitation, compact planetary nebulae are the only extended sources likely to be bright enough for detection with *Copernicus*, and these in general require a pointing accuracy of ±10" or better. It is hoped that the required accuracy will be achieved as a result of upcoming efforts to refine and calibrate pointing techniques using the IRU.

The spectrometer entrance slit is 39 arc seconds long and 0.3 arc seconds wide. The width can be changed to 1.2 arc seconds on ground command, increasingly the signal by about a factor of 2 for a stellar source, but this has generally been avoided for fear of failure in the slit transfer mechanism.

C. Guidance sensitivity

Before a Guest Investigator proposal is made, one should determine as accurately as possible that the target star is bright enough for the guidance system to settle on and to maintain attitude for the duration of the observations. This is estimated by predicting the output voltage of the Automatic Gain Control (AGC) which will occur when the Fine Error Sensor (FES) has settled on the target. When the AGC value is greater than 9.6 volts, the FES automatically turns off because the star is considered too faint to observe. In general for any star whose predicted AGC is greater than 8.6 volts the ability of the spacecraft to guide on the star will be tested before any observing time is committed.

It has been found that the most accurate and convenient index for predicting the AGC value for a star is its U magnitude, in the standard UBV system. The bandpass of the U filter matches the response function of the guidance system closely enough that in general no corrections are needed for spectral type or interstellar reddening. The AGC versus U calibration for the guidance configuration which is normally in use is shown in Figure 2 (upper curve). This can be used to predict AGC values for any star of spectral type earlier than about A3. U magnitudes for a very large number of stars can be found in the Photoelectric Catalogue of Blanco et al. (1968).

If no U magnitude is available, B and V can be used as approximate AGC predictors, but allowances must be made for both spectral class and reddening. Figure 3 shows the calibration curves for both indices and indicates the dependence on spectral type. AGC values derived from the B magnitude (upper plot in Figure 3) should be corrected for reddening by the addition of 0.8 E (B-V) volts. A correction of 2.0 E (B-V) volts should be added to AGC values derived from V magnitudes (lower plot). For example, an O star which has V = 1.6 and E (B-V) = 0.20 would have a predicted AGC of 3.0 + 2.0 (0.20) = 3.4 volts.

For stars of intermediate A and later spectral types, the actual AGC will be at least 1 V less than that predicted from U magnitudes because of a red peak in the guidance sensitivity spectrum which allows late-type stars to be acquired by the FES more easily than indicated by the UBV magnitudes. For example Theta Cas, an A7 star, has U = 4.61 (implying a predicted AGC of 7.7 volts) but an actual AGC of 6.6 volts. Alpha Boo, a K2III star, has U = 2.43 (implying AGC = 4.8 volts) and an actual AGC of 3.1 volts. In cases of doubt for faint stars, guidance tests will be performed before observing time is committed.

Recent tests of a heretofore unused guidance photomultiplier tube have allowed *Copernicus* to guide successfully on stars a full magnitude fainter than previously possible; i.e. with this guidance configuration, it is possible to guide on an unreddened early B star of visual magnitude 7.5. Only very hot and largely unreddened stars of such faintness in V are bright enough in the ultraviolet to produce a detectable signal in the *Copernicus* spectrometer, but even so, use of this configuration adds substantially to the number of feasible target stars which are available for study through use of long integration times. It is anticipated that the new guidance configuration will be used only periodically, so that degradation of its sensitivity can be minimized. The U magnitude vs. AGC calibration for this guidance channel is shown in Figure 2 (lower curve).

D. Experiment efficiency

In order to estimate the expected spectrometer count rate for a proposed target star, the efficiency curves shown in Figure 4 should be used. These curves, which give the 14 sec count rate as a percentage of the photon flux incident on the unocculted 2914 cm² of the primary mirror, are based on calibrated rocket data compiled by R.C. Bohlin (private communication) for the star Eta UMa. Shortward of 1200 Å, the efficiencies are based on model atmospheres calculations, there being no calibrated data available at present. The curves of Figure 4 take into account degradation which has occurred since launch, primarily shortward of 1100 Å. The degradation is wavelength dependent (greater at the shorter wavelengths), but the time dependence is not known in detail. Detectable changes in sensitivity over a 6 month interval should be expected.

Several calibration techniques are being applied by Guest Investigators and should soon be in the literature. In addition, the degradation of the optical system as a function of wavelength is monitored on a semi annual basis.

In view of the uncertainty in model absolute photon fluxes in the far ultraviolet, it is advisable to avoid total reliance on theoretical models in estimating predicted *Copernicus* count rates. If no rocket or other far UV observations are available, the typical count rates shown in Tables 2-5 for stars of a variety of spectral types may be useful. Corrections for distance, absolute magnitude, and interstellar extinction differences must of course be made. The UV extinction curve derived by a previous OAO experiment (Bless and Savage, 1972) is reproduced in Figure 5. Although there is substantial variation between different stars in the shape of the UV extinction curve, Figure 5 and the results of York et al. (1973) are helpful in estimation *Copernicus* count rates from Tables 2-5.

E. Photometric accuracy

Characteristics of the photometry are described by Rogerson et al. (1973), and will not be repeated here in any detail. Briefly, tubes U1 and U2 are normally photon noise limited over the time required to scan an interstellar line.

The count rate due to background particles is very large for V1 and V2, significantly reducing the photometric accuracy and usefulness of these phototubes, except for very bright stars. The dark count in U1 and U2 caused by these particles is generally insignificant except when the spacecraft is in the South Atlantic Anomaly, where observations are not normally made.

The chief contributor to the large fluctuations of dark count in the near-UV tubes is the presence of bursts of photoelectrons, produced by cosmic rays, which strike the photocells several times per second. It has recently been found that, if cumulative photon counts are stored every 1/8 second instead of once each 14 sec, this random noise can be greatly reduced by rejecting those 1/8-sec time frames which contain high counts due to cosmic rays.

In this way it is possible to reduce the rms fluctuation of dark count in tubes V1 and V2 from about 400 in 14 seconds to roughly N, where N is the total 14-second count (which contains a contribution of typically 3500 counts in 14 seconds, probably caused by phosphorescence following passage through the South Atlantic Anomaly). Because data storage in this mode occurs every 1/8 sec rather than every 14 sec, spacecraft memory becomes filled in 4 minutes, and less time per orbit can be used for observing than in the normal mode. This special observing technique is mainly for use with V1, the high-resolution near-UV tube. Proposals are invited for use of this mode for particularly important problems requiring accurate V1 measures over a narrow wavelength range. Scientific programming and final data presentation will be essentially the same as for the standard operating mode.

Particle background counts for standard 14-second integration are routinely predicted as a function of latitude and longitude at the time of observation. Figure 6 shows an example of the range in counts which may be encountered within a given orbit. A detailed description of the algorithms used is available on request. In addition, dark counts are taken about once every four orbits, and these can be used to provide time correction factors to the routinely predicted background counts. The predictions are based on data taken during the first eight months of operation, and may be systematically in error, due for instance to changes in solar activity.

For cases where particle background limits the usefulness of V1 or V2 data, observations can be restricted to particular orbits which provide minimum background counts (at a substantial reduction in observing efficiency), or the high time resolution mode described above may be used. For stars fainter than third magnitude routinely scheduled V1 and V2 observations are of minimal use.

The spacecraft pointing accuracy, which is generally about 0.02 seconds of arc during a period of a few minutes, is good enough so that photon counts during single scans of spectrum lines are usually not noticeably affected by guidance changes. Over a period of several hours, changes in spacecraft pointing can cause changes of 5 to 10% in the photon counts. To achieve the highest accuracy in scanning lines with U1, carriage 2 can be held motionless during each scan and the data from U2 can be used to smooth out fluctuations in U1 which are due to spacecraft pointing changes.

A more serious problem is stray light which enters photomultioliers U1 and U2 through vent holes in the phototube mounts. The stray light problems have been discussed by Rogerson, Spitzer, et al. (1973) and York et al. (1973). Details of the correction of U2 data for the stray light problem are available on request. The correction algorithm has been developed by Dr. Ralph Bohlin (GSFC) and is described by him (Bohlin, 1975). The U2 spectrum can be corrected to an accuracy of about sqrt[$(.03)^2+a^2$], where a is the fractional uncertainty introduced by guidance drifts, (generally, a < 0.1) providing about 60 Å of spectrum is available longward of the longest wavelength of interest for a particular program, and providing a continuing U2 scan is available over the region of interest. Hence, this additional region should be included in observations planned by a Guest Investigator. For cases where complete U2 spectra are available, the corrections can be made at Princeton, upon request.

The stray light on tube U1 can be eliminated by judiciously positioning the carriage 2 dipping mirror in front of the stray light hole for tube U1, as described in Section IV.C.6, below. For O and B stars, scattered light from the optical surfaces amounts to about 10% of the local continuum for 1000 Å < lambda < 1400 Å and <5% of the continuum for 1800 Å < lambda < 3200 Å. For the remaining accessible regions of the spectrum, the scattered light from other parts of the spectrum may be equal to or greater than the observed intensity of the stellar spectrum due to the low optical efficiency in these wavelength regions. For cooler stars, the scattered light becomes significant at somewhat longer wavelengths.

In most cases, the scattered light must be determined by noting the residual intensity at the bottom of saturated stellar or interstellar lines.

Copernicus Instrument Description

Mission Overview

The third Orbiting Astronomical Observatory (OAO-3, OAO3, or OAO-C) named Copernicus, was launched from Cape Kennedy on the 21 August 1972. The Copernicus satellite contained two co-aligned astronomical instruments, the "Princeton Experiment Package" (PEP), a telescope-spectrometer designed for high-resolution studies of absorption lines in the interstellar medium, and a cosmic X-ray experiment provided by UCL/MSSL (further information on the X-ray experiments can be obtained from HEASARC). The Copernicus satellite was when launched the heaviest unmanned space observatory, and was placed in a nearly circular 745 km altitude orbit inclined 35 degrees to the equatorial plane. The telescope-spectrometer was a 32-inch diameter reflecting telescope and ultraviolet spectrometer system designed, built, and operated by the Princeton University Observatory (Principal investigator Lyman Spitzer, Jr.), and was designed to obtain ultraviolet spectra especially in the rich 900-1200 A wavelength region. Between August 1972 and February 1982 a total of 549 different objects were observed (plus measurements of air-glow and geocoronal Lyman-alpha emission), and 687,960 separate scans were obtained.

Instrument Description

The Copernicus telescope-spectrometer (described in Rogerson et al. 1973a, and the Guest Investigator's Guide available on-line) used a cassegrain telescope with a f/3.4 primary of fused silica with a clear aperture of 80 cm and a fused silica secondary with a clear aperture of 7.5 cm. The optical surfaces were Al over-coated with LiF. The equivalent focal length at the spectrometer entrance slit (the cassegrain f/20 focus) was 1589 cm, with the spectrometer placed in front of the primary mirror (blocking approximately 42% of the primary aperture); the following is a diagram showing the "Princeton Experiment Package":

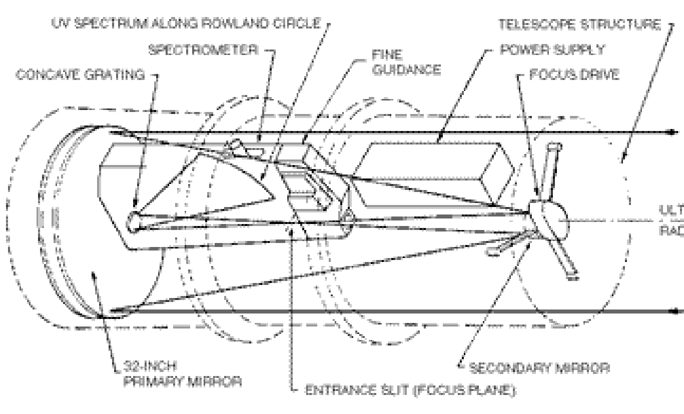

Figure 1. The Princeton telescope-spectrometer on Copernicus. Dashed lines: telescope structural wall and supporting rings. Solid lines: telescope and instrumentation.

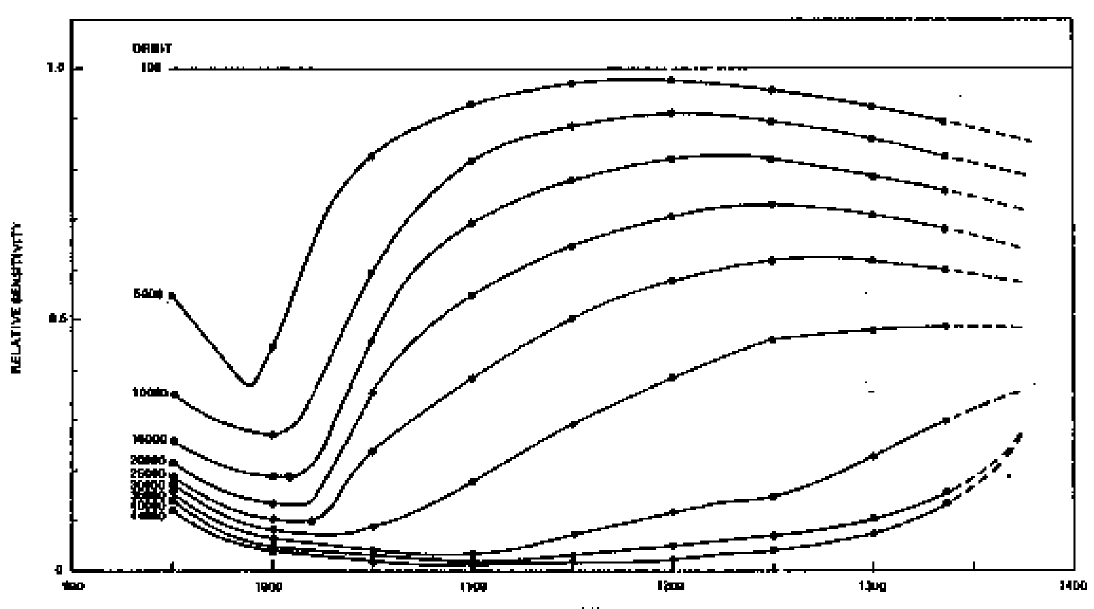
The spectrometer was of the Paschen-Runge type with a concave grating focusing the spectrum on a 1-meter Rowland circle with a dispersion in first order of 4.2 Å per millimeter (a general discussion of such spectrographs is provided, for example, in Kitchin's book Astrophysical Techniques, chapters 4.1-4.2, in particular see Figure 4.1.12). The entrance slit (3 mm by 24.2 micron) corresponded to 39.0" x 0.314" on the sky. Two movable carriages each carrying two photomultiplier tubes were used to scan the spectrum, the U tubes were generally sensitive only in the second order, while the V tubes were restricted to the near-ultraviolet (V1 by a fused silica filter and V2 by a sapphire prism). The nominal instrumental widths (FWHM) are 0.10 Å in first order (V1 and occasionally U1) and 0.05 Å in second order (most U1 scans); for U2 and V2 the widths are about 4 times larger. There was a diagonal mirror in front of carriage 2 (holding the U2 and V2 tubes) to prevent physical interference. Another tube (U3/V3) was fixed at 3430 Å and used to monitor photometric errors due to image motion in the narrow entrance slit. The U1 and U2 tubes were generally restricted to wavelengths greater than the Lyman-limit (912 Å), although the carriages allowed observations to wavelengths as short as 710 Å. The U1 carriage could also be used in 1st order on bright stars to obtain spectra at wavelengths longer than 1500 Å, but even for the brightest stars this was generally limited to wavelengths between 1500 and 1560 Å.

Phototube	Carriage Number	Order	Nominal FWHM (Å)	Nominal Wavelength Coverage (Å)
U1	1	2	0.05	912-1500
		1	0.10	1500-1560
V1	1	1	0.10	1640-3185
U2	2	2	0.20	912-1645
V2	2	1	0.40	1480-3275

The electronics system provided for pulse counting of the signals from the data tubes during a nominal 14-second integration period (the actual time was 13.76 seconds) while the carriages were motionless, the carriages were then moved to the next position and a new integration started. The U tubes had a slowly varying dark count rate approximately equal to the flux of cosmic rays through the front of these tubes, while the V tubes had a large rapidly fluctuating dark count rate that seriously limited the photometric precision obtainable with the V1 and V2 tubes (although this could be largely removed by using a special scan mode, see for example Barker et al. 1984). Stray light from the target reached the U1 and U2 tubes through vent (outgassing) holes in the spectrograph, but this could be eliminated for the U1 tube by positioning carriage-2 to block light just longward of the U1 exit slit (see Rogerson et al. 1973b; York et al. 1973). A residual background of about 10 percent of the continuum was present for observations using the U1 tube longward of 1000 Å, presumably due to scattering from the optics. At the shortest wavelengths the scattered light could be greater than the observed intensity from the star due to the reduced efficiency at short wavelengths. The wavelength dependence of the scattered light is similar for the V1 tube). In most cases the scattered light correction must be derived from the residual counts in the bottom of saturated stellar or interstellar lines (see Rogerson et al. 1973b; Morton 1975; Bohlin et al. 1983). The correction of U2 data for stray light is described by Bohlin (1975). During the short time required to record a single scan the telescope typically oscillated by an amplitude of about 0.02 arcsecond, which was good enough so that the counts were usually not noticeably affected by guidance changes (Rogerson et al. 1973a; Bohlin et al. 1983). To achieve the highest photometric accuracy with U1, carriage 2 could be held motionless during each scan and the data from U2 used to smooth out fluctuations in U1 which are due to spacecraft pointing changes (this technique was used primarily for observations of the Lyman lines of Hydrogen and Deuterium).

There was a wavelength dependent decrease in the sensitivity of Copernicus over the duration of the mission (Polidan 1981; Bohlin et al. 1983). Over the first 5 years (27,000 orbits) the U1 and U2 tubes declined in sensitivity as expected as surfaces were contaminated, electronics decayed, and similar effects took their toll; however, there was a rapid and unexpected decrease in efficiency (particularly near 1100 Å) during the sixth year of operations. Tests of the high voltage units and the instrument focus suggested that the most likely cause of the decay was contamination of optical surfaces (Polidan 1981). It appears that material, either from outgassing or from a lubricant leak, had coated the optical surfaces and then had polymerized when it came in contact with Oxygen. The period of rapid decline corresponded to Solar maximum, when the Earth's atmosphere is expanded and there is additional Oxygen at the height of the Copernicus orbit. Similar behavior was also observed in the TIROS and Nimbus spacecraft during the same time interval due to polymerized outgassed material. The decline in sensitivity of the U1 tube is shown in the following graph from Polidan (1981):



For the V1 and V2 tubes the decline was less severe, the V tubes retained 60% of their pre-launch sensitivity (Polidan 1981).

Copernicus Instrument Performance

The following sections have been extracted from the *Final OAO-C Copernicus Operations Report* prepared by Princeton University in September 1981. They concern the optical performance and instrument characteristics throughout the duration of the mission

---

Section 1: Summary of Instrument Performance

Guidance

While the Princeton Experiment Package (PEP) was gathering stellar data, the pointing was maintained by centering the stellar image on the slit jaws of the experiment using the Fine Error Sensor (FES). To ensure that the guidance characteristics were similar over the range of stellar brightnesses observed, the high voltage of the FES was determined by an automatic gain control (AGC) that depended on stellar magnitude. During the mission, stars between -1.5 and 7.0 visual magnitude were regularly observed.

[...]

Spectrometer Telescope

Throughout the mission of the PEP, both spectrometer carriages performed at nominal design specification. No mechanical anomalies were ever noted. Before the OAO-C launch, carriage 2 was discovered to have a low-rate leak in its sealed lead-screw bellows assembly. This was considered, however, to have little consequence over the anticipated 1-year lifetime of the PEP, and a decision was made to continue with launch preparations.

The commanded carriage motion was extremely predictable, and all deviations from expected behavior were traced to electronic glitches, operational programming errors, or a lack of understanding of the nonstandard operation of the carriage motion control subsystem (special programs, configurations, *etc.*).

The static position indicators for both carriages possessed a known inherent ambiguity that occasionally resulted in a scientific data loss because of incorrect interpretation of the carriage position status by operations personnel. On several occasions, the carriages were also inadvertently commanded to positions beyond their normal ranges of travel, but in each instance, the electrical limit switches were activated, and the motion of the carriages was halted be fore any physical stop was met.

The obscuration pattern of carriage 1 sensors by the carriage 2 collection mirror was determined early in the mission, and this effect was included, when necessary, in the observing programs. Stray light entering the vent ports of the far-UV sensors was also recognized as a problem. This effect was much reduced by judicious operations programs and data reduction correction procedures.

[...]

Optical Performance

The overall performance of the "optical" system (mirrors, phototubes, and associated electronics) was within expected limits for the first 5 years of the mission. Shortly after launch, telemetry indicated that the secondary mirror had not positioned itself properly. A check of the image size and shape in orbits 168-170 showed the image to be in focus. It was concluded that the secondary mirror was positioned correctly and that the telemetry was bad. A second check of the image size was performed in orbits 35250-35260 and showed no significant change in the image. A third set of image data obtained during the last month of the mission was lost. It is believed, however, that the image size and shape were maintained throughout the mission.

The only major change in performance occurred in the experiment far-UV sensitivity. During the first 5 years of the mission, the decline in instrument sensitivity was similar to that predicted before launch: the largest decline occurred the first year with the shortest wavelengths being the most affected. Beginning near orbits 25000-30000, the decline in sensitivity accelerated, dropping by a factor of 5 in 1 year, with the largest decline occurring at the middle, rather than shortest, wavelengths. This decline continued throughout the remaining 3 years of the mission. Investigation of the cause for this decline is still underway. The best explanation at this time is that the decline is due to contamination of the optical surfaces in the spectrograph by an unknown material. The onset of the rapid sensitivity degradation in 1977 corresponds to the onset of solar maximum, suggesting that a process similar to that found in the Television Infrared Observation Satellite (Tiros) is working (Reference: *Tiros Project Memo* of October 12, 1979). Details of the decline in sensitivity can be found in Section 2.

No failure of any component in the optical system was recorded during the mission. All six phototubes and their associated electronics were functioning at termination.

Section 2: Malfunctions and Resultant Impact

Mechanical Failures

The few failures that occurred within the PEP did not compromise or severely limit its basic scientific mission. These failures are itemized as follows:

a. Secondary Mirror/Focus Mechanism

> During the immediate post launch checkout of the PEP, status data indicated incomplete uncaging of the telescope's secondary mirror/focus mechanism assembly. Subsequent data analyses suggested failure of the telemetry monitor circuits and not of the uncaging operation.
>
> An attempt to change the telescope focus in orbit was also unsuccessful. Position status data of the secondary mirror implied that no motion was produced by commanding. Because the final focus adjustment prior to launch was calculated to include the effects of the launch environment, the telescope was believed to be near best focus. Image shape tests confirmed this status. End-of-mission attempts were made to move the secondary mirror, but again, no motion was observed.

b. Calibration Lamps

> Postlaunch checkout of the calibration lamps confirmed launch survival and no significant changes in the spectrometer wavelength calibration. The lamps were infrequently used thereafter. During a special series of observations about one third into mission lifetime, however, both lamps failed to operate. End-of-mission attempts to ignite calibration lamp A were unsuccessful.

[...]

Sensitivity Degradation and Effects

The principal malfunction in the PEP was the rapid decline in the far-UV sensitivity. The decision to terminate the spacecraft was based partly on the loss of far-UV sensitivity. Figure 2-1 shows the relative sensitivity of the high-resolution far-UV phototube U1 from orbits 100 to 44000. In the first 25000 orbits (5 years), the decline was close to that predicted be fore launch. A rapid (approximately 50 percent) decline at shorter wavelengths was experienced during the first year followed by smaller declines in subsequent years. At longer wavelengths, the decline was more gradual and reasonably constant (approximately 10 to 15 percent per year) through the first 25000 orbits.

After orbit 25000, the character of the decline was significantly different. At the shortest wavelengths (<1000 Å), a slow decline continued until termination. At the middle wavelengths (1000 to 1300 Å), a dramatic decline occurred. Between orbits 30000 and 35000, the sensitivity of the U1 tube decreased by a factor of 2.25 at 1100 Å. By orbit 40000, another factor of 5 was lost. Thus, in 10000 orbits, more than a factor of 10 was lost. At longer wavelengths (>1300 Å), the decline was not as rapid (a factor of 4 in 10000 orbits), but it was larger than that observed before orbit 25000.

The low-resolution far-UV phototube U2 exhibited a behavior similar to that of U1. The only significant difference was that during the period of rapid decline (orbits 25000-44000), it showed a greater decline than U1. The U2 wavelength dependence was similar to that of U1.

The near-UV phototubes, V1 and V2, did not exhibit the rapid decline seen in the far-UV phototube. They displayed an initial rapid decline followed by a much slower decline until the end of the mission. At orbit 25000, both V1 and V2 were at approximately 70 percent of their launch sensitivity. By orbit 44000, they still retained 60 percent of their sensitivity at launch.

Clearly, something occurred between orbits 25000 and 30000 that greatly affected the sensitivity of the far-UV phototubes. This is also the period in which glitches began to occur in abundance (Section 2) [not included here]. This suggests that the two malfunctions may have the same cause or that the sensitivity decline was somehow caused by the effects of the glitches.

[...]

The initial decline in sensitivity, orbits 0-25000, is similar to that seen in other devices. The cause is thought to be primarily due to the decay of the photocathodes. The rapid decline occurring after orbit 25000 is, however, quite anomalous. Investigations conducted shortly after the onset of the rapid decline absolved the power supplies and other control units as the cause of the sensitivity loss. This left only contamination of the optical surfaces and/or photocathodes as the cause of the decline. This suspicion is further supported by the fact that U2 showed a greater decline than U1 (U2 undergoes one more reflection than U1).

At the same time that *Copernicus* was experiencing this rapid decline in sensitivity, Earth sensors on Tiros-N, NOAA-A, and 5D/1 were also noted to display significant sensitivity losses. Analysis revealed that their sensitivity loss was due to contaminants on the optical surfaces. The contaminants came from outgassed material reacting with atmospheric oxygen to produce polymers. The increased solar activity in 1977 raised the mean density of oxygen in the upper atmosphere and caused the polymer production to increase dramatically (see report from Tiros Project for details).

Analysis of the data suggests that a similar reaction may have occurred in the PEP. The most likely location for the contaminant is in the spectrograph. Ample materials exist for outgassing, and the spectrograph is open to space so that atmospheric oxygen can enter (direct observation of oxygen atoms confirms their increased abundance at the altitude of the spacecraft in 1978 through 1981). U1 and U2 show greater declines because of the peculiar absorbing properties of the contaminant. The peak absorption appears to occur between 1050 Å and 1150 Å. U2 shows more loss because the incoming light undergoes an extra reflection to enter the phototube. Further analysis is continuing. A final report on the decline and possible causes will be issued when the analysis is complete.

The impact on *Copernicus* operations caused by the loss of sensitivity was to lengthen all observations. Programs were run several times to get the data quality obtained with a single run before 1977.

Impact of V Tube Fluorescence and Short Frame

As explained in Section 1 [not included here], the background levels in the near-ultraviolet tubes (V1, V2, V3) were much larger than expected. It has been determined that passage of energetic particles (cosmic rays, particles, *etc.*) through the windows covering the tubes causes a short-term fluorescence and a long-term phosphorescence. The sum of these two components results in a background count rate of approximately 7000 counts/14 seconds in V2 and approximately 10,000 counts/14 seconds in V1. Therefore, V1 and V2 were useful only for fairly bright stars, where the stellar signal was much larger than the background. With the advent of the short frame program in 1975, the V1 tube began returning higher quality data. However, short frame observations required the use of the OBP [On-Board Processor] (except for the technique implemented in 1980, whereby the spacecraft was commanded from the ground). From 1975 to 1980, the OBP had numerous minor failures and three major failures. The major failures resulted in the OBP being inoperable from April 8 to August 7, 1977; August 30, 1978 to June 26, 1979; and June 28 to October 3, 1980, a total of 17 months.

A Guide for Guest Investigators Using the Princeton Telescope on the Satellite Copernicus

Abstract

The instrumental configuration, calibration, and operations during the first flight of the Ultraviolet Imaging Telescope on the Astro-1 mission, December 2-10, 1990, are described. The UV images of a wide variety of astronomical objects were recorded with a 40-arcmin diameter field of view. Images of targets as faint as magnitude 21 (UV) were secured with a resolution of about 3 arcsec. The optics, light baffling, and image motion compensation system are summarized, and detectors and electronic subsystems are described.

Abstract

The Ultraviolet Imaging Telescope (UIT) cameras include two-stage magnetically focused image intensifiers that introduce small but significant geometrical distortions into the data. These distortions, which create positional offsets as large as 25 arcsec at the field edges, are corrected by the procedure described here to 2-3 arcsec, approximately the resolution of the images. The distortion is measured by comparing and correcting UIT images to digitized Guidestar survey plates of the same fields. Two-dimensional third-order polynomials are used to model the distortion. The models assume that the distortion is an instrumental effect, independent of mission elapsed time and target, and that the effect of distortion is an instrumental effect, independent of mission elapsed time and target, and that the effect of distortion in the center of each field is minimal. The models are used to improve computed astrometric plate solutions and to remove the geometric distortion while transforming the image to a standard north-up, ease-left orientation.

Abstract

The Ultraviolet Imaging Telescope (\UIT) was flown as part of the \AstroMiss\ observatory on the Space Shuttle Columbia in December 1990 and again on the Space Shuttle Endeavor in March 1995. Ultraviolet (1200-3300\AA) images of a variety of astronomical objects, with a 40\arcmin\ field of view and a resolution of about 3\arcsec, were recorded on photographic film. The data recorded during the first flight is available to the astronomical community through the National Space Science Data Center (NSSDC); the data recorded during the second flight will soon be available as well. This paper discusses in detail the design, operation, data reduction, and calibration of \UIT, providing the user of the data with information for understanding and using the data. It also provides guidelines for analyzing other astronomical imagery made with image intensifiers and photographic film. (SECTION: Astronomical Instrumentation)

Abstract

We present a photometric catalog of 2244 objects detected by the Ultraviolet Imaging Telescope in the near-ultraviolet (NUV; 1650A < {lambda} < 2900 A) during the Astro Space Shuttle mission. Sources in the catalog are as faint as m_nuv_ ~ 18.8, or f_nuv_ ~ 1.1 x 10^16^ ergs s^-1^ cm^-2^ A^-1^, but the survey is not complete to this level. Optical catalogs were used to cross identify sources and derive NUV - V colors. A majority of the objects (88%) do indeed have proposed optical identifications from catalogs, and most are stars. Our purpose in creating the catalog is to form a database useful for identifying very blue objects and performing Galactic UV stellar population studies.
