

Learn Visual Basic 6.0

1. Introduction to the Visual Basic Language and Environment

Preview

- In this first class, we will do a quick overview of how to build an application in Visual Basic. You'll learn a new vocabulary, a new approach to programming, and ways to move around in the Visual Basic environment. You will leave having written your first Visual Basic program.

Course Objectives

- ⇒ Understand the benefits of using Microsoft Visual Basic 6.0 for Windows as an application tool
- ⇒ Understand the Visual Basic event-driven programming concepts, terminology, and available tools
- ⇒ Learn the fundamentals of designing, implementing, and distributing a Visual Basic application
- ⇒ Learn to use the Visual Basic toolbox
- ⇒ Learn to modify object properties
- ⇒ Learn object methods
- ⇒ Use the menu design window
- ⇒ Understand proper debugging and error-handling procedures
- ⇒ Gain a basic understanding of database access and management using databound controls
- ⇒ Obtain an introduction to ActiveX controls and the Windows Application Programming Interface (API)

What is Visual Basic?

- **Visual Basic** is a tool that allows you to develop Windows (Graphic User Interface - **GUI**) applications. The applications have a familiar appearance to the user.
- Visual Basic is **event-driven**, meaning code remains idle until called upon to respond to some event (button pressing, menu selection, ...). Visual Basic is governed by an event processor. Nothing happens until an event is detected. Once an event is detected, the code corresponding to that event (event procedure) is executed. Program control is then returned to the event processor.

- Some Features of Visual Basic
 - ⇒ Full set of objects - you 'draw' the application
 - ⇒ Lots of icons and pictures for your use
 - ⇒ Response to mouse and keyboard actions
 - ⇒ Clipboard and printer access
 - ⇒ Full array of mathematical, string handling, and graphics functions
 - ⇒ Can handle fixed and dynamic variable and control arrays
 - ⇒ Sequential and random access file support
 - ⇒ Useful debugger and error-handling facilities
 - ⇒ Powerful database access tools
 - ⇒ ActiveX support
 - ⇒ Package & Deployment Wizard makes distributing your applications simple

Visual Basic 6.0 versus Other Versions of Visual Basic

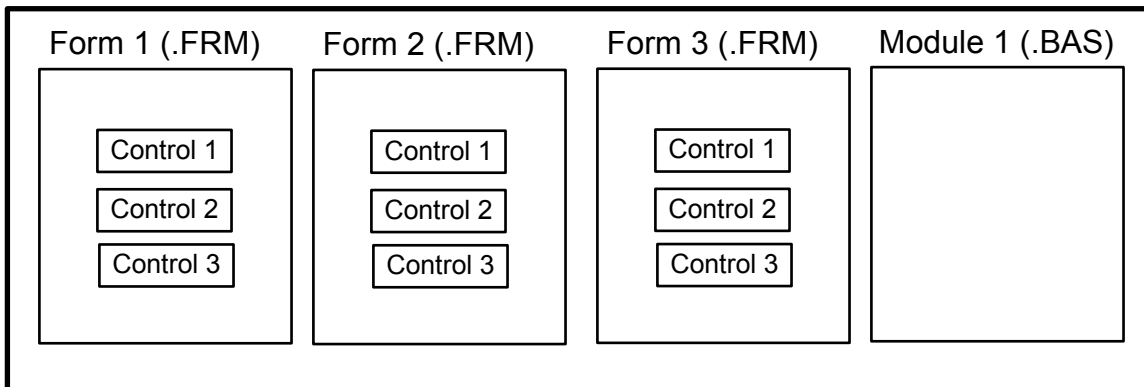

- The original Visual Basic for DOS and Visual Basic For Windows were introduced in 1991.
- Visual Basic 3.0 (a vast improvement over previous versions) was released in 1993.
- Visual Basic 4.0 released in late 1995 (added 32 bit application support).
- Visual Basic 5.0 released in late 1996. New environment, supported creation of ActiveX controls, deleted 16 bit application support.
- And, now Visual Basic 6.0 - some identified new features of Visual Basic 6.0:
 - ⇒ Faster compiler
 - ⇒ New ActiveX data control object
 - ⇒ Allows database integration with wide variety of applications
 - ⇒ New data report designer
 - ⇒ New Package & Deployment Wizard
 - ⇒ Additional internet capabilities

16 Bits versus 32 Bits

- Applications built using the Visual Basic 3.0 and the 16 bit version of Visual Basic 4.0 will run under Windows 3.1, Windows for Workgroups, Windows NT, or Windows 95
- Applications built using the 32 bit version of Visual Basic 4.0, Visual Basic 5.0 and Visual Basic 6.0 will only run with Windows 95 or Windows NT (Version 3.5.1 or higher).
- In this class, we will use Visual Basic 6.0 under Windows 95, recognizing such applications will not operate in 16 bit environments.

Structure of a Visual Basic Application

Project (.VBP, .MAK)

Application (Project) is made up of:

- ⇒ **Forms** - Windows that you create for user interface
- ⇒ **Controls** - Graphical features drawn on forms to allow user interaction (text boxes, labels, scroll bars, command buttons, etc.) (Forms and Controls are **objects**.)
- ⇒ **Properties** - Every characteristic of a form or control is specified by a property. Example properties include names, captions, size, color, position, and contents. Visual Basic applies default properties. You can change properties at design time or run time.
- ⇒ **Methods** - Built-in procedure that can be invoked to impart some action to a particular object.
- ⇒ **Event Procedures** - Code related to some object. This is the code that is executed when a certain event occurs.
- ⇒ **General Procedures** - Code not related to objects. This code must be invoked by the application.
- ⇒ **Modules** - Collection of general procedures, variable declarations, and constant definitions used by application.

Steps in Developing Application

- There are three primary steps involved in building a Visual Basic application:
 1. **Draw the user interface**
 2. **Assign properties** to controls
 3. **Attach code** to controls

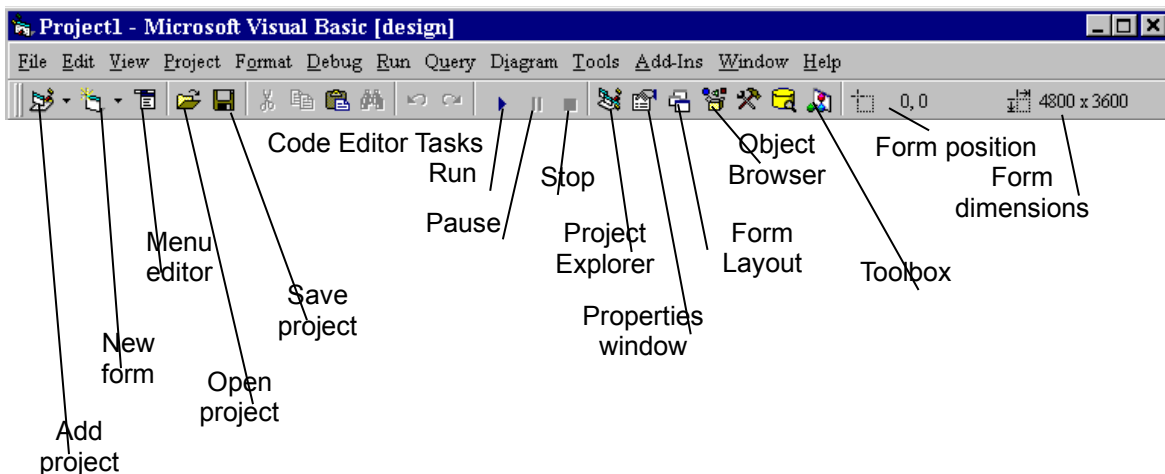

We'll look at each step.

Drawing the User Interface and Setting Properties

- Visual Basic operates in three modes.
 - ⇒ **Design** mode - used to build application
 - ⇒ **Run** mode - used to run the application
 - ⇒ **Break** mode - application halted and debugger is available

We focus here on the **design** mode.

- Six windows appear when you start Visual Basic.
 - ⇒ The **Main Window** consists of the title bar, menu bar, and toolbar.
 - The title bar indicates the project name, the current Visual Basic operating mode, and the current form. The menu bar has drop-down menus from which you control the operation of the Visual Basic environment. The toolbar has buttons that provide shortcuts to some of the menu options. The main window also shows the location of the current form relative to the upper left corner of the screen (measured in twips) and the width and length of the current form.

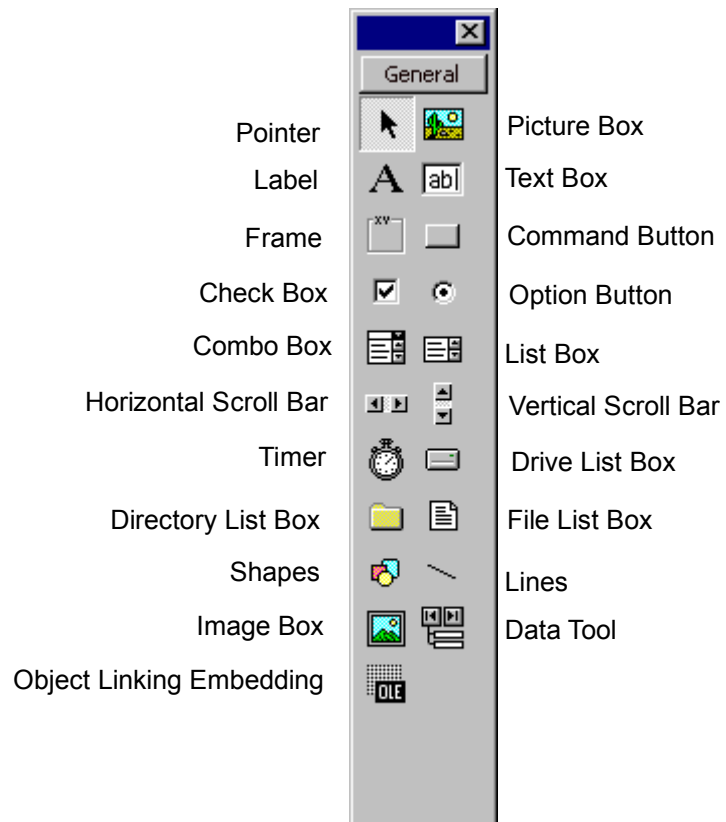

1-6 Learn Visual Basic 6.0

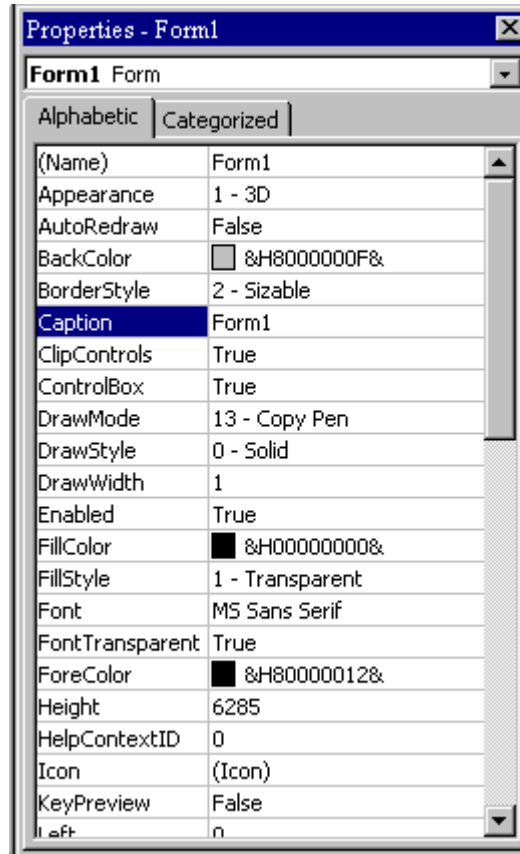

- ⇒ The **Form Window** is central to developing Visual Basic applications. It is where you draw your application.

- ⇒ The **Toolbox** is the selection menu for controls used in your application.

- ⇒ The **Properties Window** is used to establish initial property values for objects. The drop-down box at the top of the window lists all objects in the current form. Two views are available: Alphabetic and Categorized. Under this box are the available properties for the currently selected object.

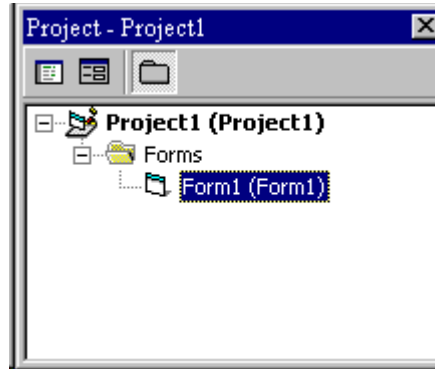

- ⇒ The **Form Layout Window** shows where (upon program execution) your form will be displayed relative to your monitor's screen:

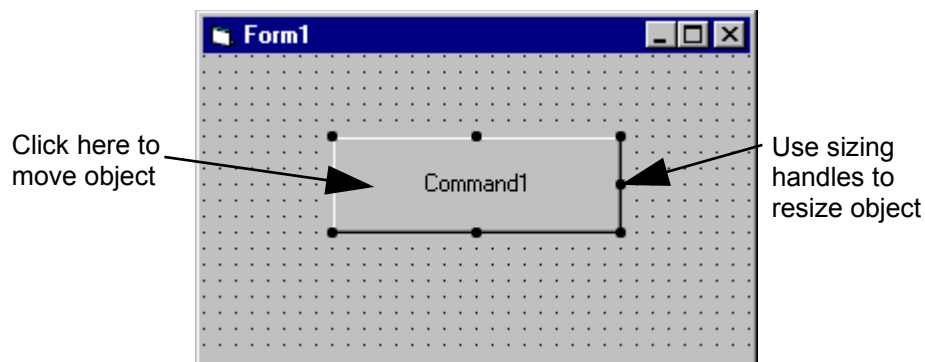

1-8 Learn Visual Basic 6.0

⇒ The **Project Window** displays a list of all forms and modules making up your application. You can also obtain a view of the **Form** or **Code** windows (window containing the actual Basic coding) from the Project window.

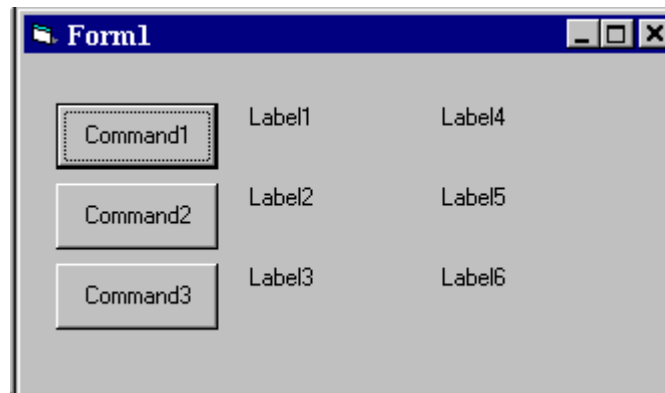

- As mentioned, the user interface is 'drawn' in the form window. There are two ways to place controls on a form:
 1. Double-click the tool in the toolbox and it is created with a default size on the form. You can then move it or resize it.
 2. Click the tool in the toolbox, then move the mouse pointer to the form window. The cursor changes to a crosshair. Place the crosshair at the upper left corner of where you want the control to be, press the left mouse button and hold it down while dragging the cursor toward the lower right corner. When you release the mouse button, the control is drawn.
- To **move** a control you have drawn, click the object in the form window and drag it to the new location. Release the mouse button.
- To **resize** a control, click the object so that it is select and sizing handles appear. Use these handles to resize the object.

Example 1-1

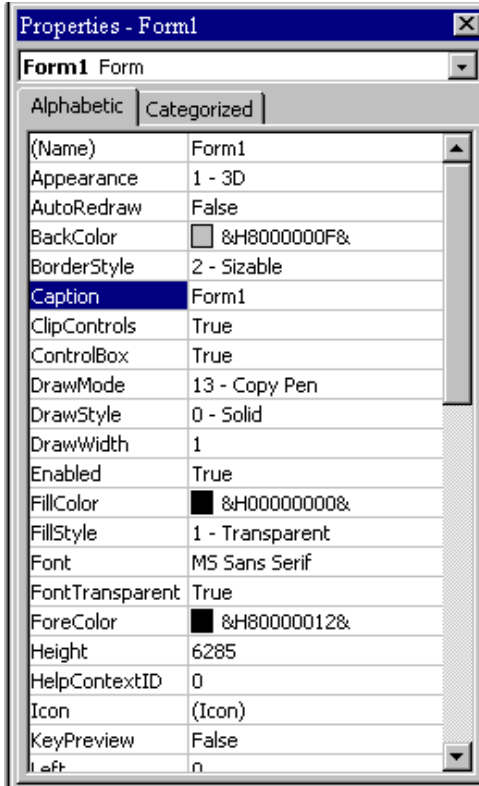

Stopwatch Application - Drawing Controls

1. Start a new project. The idea of this project is to start a timer, then stop the timer and compute the elapsed time (in seconds).
2. Place three command buttons and six labels on the form. Move and size the controls and form so it looks something like this:

Setting Properties of Objects at Design Time

- Each form and control has **properties** assigned to it by default when you start up a new project. There are two ways to display the properties of an object. The first way is to click on the object (form or control) in the form window. Then, click on the Properties Window or the Properties Window button in the tool bar. The second way is to first click on the Properties Window. Then, select the object from the **Object** box in the Properties Window. Shown is the Properties Window for the stopwatch application:

The drop-down box at the top of the Properties Window is the **Object** box. It displays the name of each object in the application as well as its type. This display shows the **Form** object. The **Properties** list is directly below this box. In this list, you can scroll through the list of properties for the selected object. You may select a property by clicking on it. Properties can be changed by typing a new value or choosing from a list of predefined settings (available as a drop down list). Properties can be viewed in two ways: **Alphabetic** and **Categorized**.

A very important property for each object is its **name**. The name is used by Visual Basic to refer to a particular object in code.

- A convention has been established for naming Visual Basic objects. This convention is to use a three letter prefix (depending on the object) followed by a name you assign. A few of the prefixes are (we'll see more as we progress in the class):

Object	Prefix	Example
Form	frm	frmWatch
Command Button	cmd, btn	cmdExit, btnStart

Label	lbl	lblStart, lblEnd
Text Box	txt	txtTime, txtName
Menu	mnu	mnuExit, mnuSave
Check box	chk	chkChoice

1-12 Learn Visual Basic 6.0

- Object names can be up to 40 characters long, must start with a letter, must contain only letters, numbers, and the underscore (_) character. Names are used in setting properties at run time and also in establishing procedure names for object events.

Setting Properties at Run Time

- You can also set or modify properties while your application is running. To do this, you must write some code. The code format is:

```
ObjectName.Property = NewValue
```

Such a format is referred to as dot notation. For example, to change the **BackColor** property of a form name **frmStart**, we'd type:

```
frmStart.BackColor = BLUE
```

How Names are Used in Object Events

- The names you assign to objects are used by Visual Basic to set up a framework of event-driven procedures for you to add code to. The format for each of these subroutines (all object procedures in Visual Basic are subroutines) is:

```
Sub ObjectName_Event (Optional Arguments)
    .
    .
End Sub
```

- Visual Basic provides the **Sub** line with its arguments (if any) and the **End Sub** statement. You provide any needed code.

Example 1-2**Stopwatch Application - Setting Properties**

1. Set properties of the form, three buttons, and six labels:

Form1:

BorderStyle	1-Fixed Single
Caption	Stopwatch Application
Name	frmStopWatch

Command1:

Caption	&Start Timing
Name	cmdStart

Command2:

Caption	&End Timing
Name	cmdEnd

Command3:

Caption	E&xit
Name	cmdExit

Label1:

Caption	Start Time
---------	------------

Label2:

Caption	End Time
---------	----------

Label3:

Caption	Elapsed Time
---------	--------------

Label4:

BorderStyle	1-Fixed Single
Caption	[Blank]
Name	lblStart

Label5:

BorderStyle	1-Fixed Single
Caption	[Blank]
Name	lblEnd

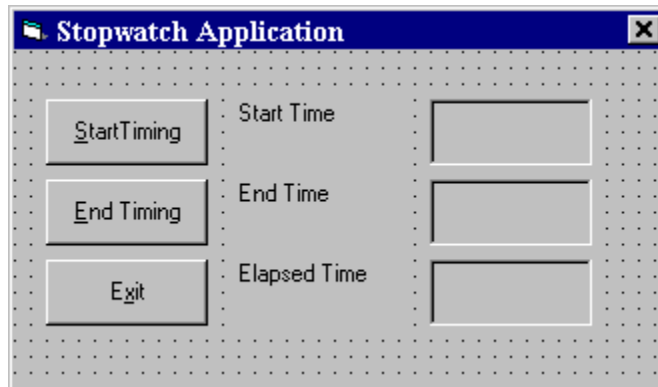

1-14 Learn Visual Basic 6.0

Label6:

BorderStyle	1-Fixed Single
Caption	[Blank]
Name	lblElapsed

In the **Caption** properties of the three command buttons, notice the ampersand (&). The ampersand precedes a button's **access key**. That is, in addition to clicking on a button to invoke its event, you can also press its access key (no need for a mouse). The access key is pressed in conjunction with the **Alt** key. Hence, to invoke 'Begin Timing', you can either click the button or press Alt+B. Note in the button captions on the form, the access keys appear with an underscore ().

2. Your form should now look something like this:

Variables

- We're now ready to attach code to our application. As objects are added to the form, Visual Basic automatically builds a framework of all event procedures. We simply add code to the event procedures we want our application to respond to. But before we do this, we need to discuss **variables**.
- Variables are used by Visual Basic to hold information needed by your application. Rules used in naming variables:
 - ⇒ No more than 40 characters
 - ⇒ They may include letters, numbers, and underscore (_)
 - ⇒ The first character must be a letter
 - ⇒ You cannot use a reserved word (word needed by Visual Basic)

Visual Basic Data Types

Data Type	Suffix
Boolean	None
Integer	%
Long (Integer)	&
Single (Floating)	!
Double (Floating)	#
Currency	@
Date	None
Object	None
String	\$
Variant	None

Variable Declaration

- There are three ways for a variable to be typed (declared):
 1. Default
 2. Implicit
 3. Explicit
- If variables are not implicitly or explicitly typed, they are assigned the **variant** type by **default**. The variant data type is a special type used by Visual Basic that can contain numeric, string, or date data.

1-16 Learn Visual Basic 6.0

- To **implicitly** type a variable, use the corresponding suffix shown above in the data type table. For example,

```
TextValue$ = "This is a string"
```

creates a string variable, while

```
Amount% = 300
```

creates an integer variable.

- There are many advantages to **explicitly** typing variables. Primarily, we insure all computations are properly done, mistyped variable names are easily spotted, and Visual Basic will take care of insuring consistency in upper and lower case letters used in variable names. Because of these advantages, and because it is good programming practice, we will explicitly type all variables.
- To **explicitly** type a variable, you must first determine its **scope**. There are four levels of scope:
 - ⇒ Procedure level
 - ⇒ Procedure level, static
 - ⇒ Form and module level
 - ⇒ Global level
- Within a procedure, variables are declared using the **Dim** statement:

```
Dim MyInt as Integer  
Dim MyDouble as Double  
Dim MyString, YourString as String
```

Procedure level variables declared in this manner do not retain their value once a procedure terminates.

- To make a procedure level variable retain its value upon exiting the procedure, replace the Dim keyword with **Static**:

```
Static MyInt as Integer  
Static MyDouble as Double
```

- Form (module) level variables retain their value and are available to all procedures within that form (module). Form (module) level variables are declared in the **declarations** part of the **general** object in the form's (module's) code window. The **Dim** keyword is used:

```
Dim MyInt as Integer  
Dim MyDate as Date
```

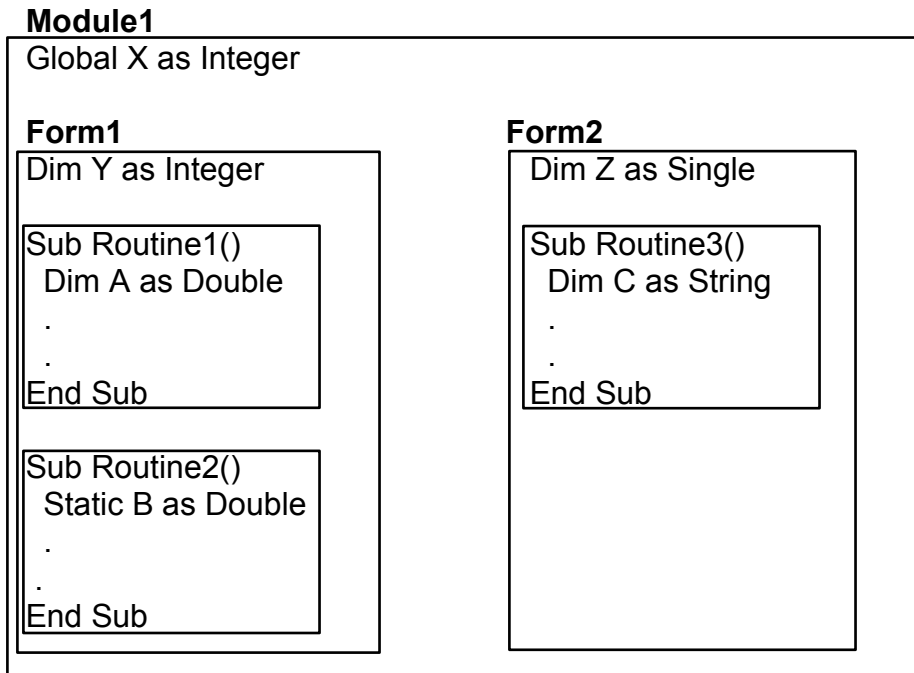

- Global level variables retain their value and are available to all procedures within an application. Module level variables are declared in the **declarations** part of the **general** object of a module's code window. (It is advisable to keep all global variables in one module.) Use the **Global** keyword:

```
Global MyInt as Integer  
Global MyDate as Date
```

- What happens if you declare a variable with the same name in two or more places? More local variables **shadow** (are accessed in preference to) less local variables. For example, if a variable MyInt is defined as Global in a module and declared local in a routine MyRoutine, while in MyRoutine, the local value of MyInt is accessed. Outside MyRoutine, the global value of MyInt is accessed.

1-18 Learn Visual Basic 6.0

- Example of Variable Scope:

Procedure Routine1 has access to X, Y, and A (loses value upon termination)

Procedure Routine2 has access to X, Y, and B (retains value)

Procedure Routine3 has access to X, Z, and C (loses value)

Example 1-3

Stopwatch Application - Attaching Code

All that's left to do is attach code to the application. We write code for every event a response is needed for. In this application, there are three such events: clicking on each of the command buttons.

1. Double-click anywhere on the form to open the code window. Or, select 'View Code' from the project window.
2. Click the down arrow in the Object box and select the object named (**general**). The Procedure box will show (**declarations**). Here, you declare three form level variables:

```
Option Explicit
Dim StartTime As Variant
Dim EndTime As Variant
Dim ElapsedTime As Variant
```

The **Option Explicit** statement forces us to declare all variables. The other lines establish **StartTime**, **EndTime**, and **ElapsedTime** as variables global within the form.

3. Select the **cmdStart** object in the Object box. If the procedure that appears is not the Click procedure, choose **Click** from the procedure box. Type the following code which begins the timing procedure. Note the **Sub** and **End Sub** statements are provided for you:

```
Sub cmdStart_Click ()
`Establish and print starting time
StartTime = Now
lblStart.Caption = Format(StartTime, "hh:mm:ss")
lblEnd.Caption = ""
lblElapsed.Caption = ""
End Sub
```

In this procedure, once the **Start Timing** button is clicked, we read the current time and print it in a label box. We also blank out the other label boxes. In the code above (and in all code in these notes), any line beginning with a single quote (') is a comment. You decide whether you want to type these lines or not. They are not needed for proper application operation.

4. Now, code the **cmdEnd** button.

```
Sub cmdEnd_Click ()
    `Find the ending time, compute the elapsed time
    `Put both values in label boxes
    EndTime = Now
    ElapsedTime = EndTime - StartTime
    lblEnd.Caption = Format(EndTime, "hh:mm:ss")
    lblElapsed.Caption = Format(ElapsedTime, "hh:mm:ss")
End Sub
```

Here, when the **End Timing** button is clicked, we read the current time (**End Time**), compute the elapsed time, and put both values in their corresponding label boxes.

5. And, finally the **cmdExit** button.

```
Sub cmdExit_Click ()
    End
End Sub
```

This routine simply ends the application once the **Exit** button is clicked.

6. Did you notice that as you typed in the code, Visual Basic does automatic syntax checking on what you type (if you made any mistakes, that is)?
7. Run your application by clicking the **Run** button on the toolbar, or by pressing <f5>. Pretty easy, wasn't it?
8. Save your application - see the **Primer** on the next page. Use the **Save Project As** option under the **File** menu. Make sure you save both the form and the project files.

9. If you have the time, some other things you may try with the Stopwatch Application:
- A. Try changing the form color and the fonts used in the label boxes and command buttons.
 - B. Notice you can press the 'End Timing' button before the 'Start Timing' button. This shouldn't be so. Change the application so you can't do this. And make it such that you can't press the 'Start Timing' until 'End Timing' has been pressed. Hint: Look at the command button **Enabled** property.
 - C. Can you think of how you can continuously display the 'End Time' and 'Elapsed Time'? This is a little tricky because of the event-driven nature of Visual Basic. Look at the **Timer** tool. Ask me for help on this one.

Quick Primer on Saving Visual Basic Applications:

When saving Visual Basic applications, you need to be concerned with saving both the forms (.FRM) and modules (.BAS) and the project file (.VBP). In either case, make sure you are saving in the desired directory. The current directory is always displayed in the Save window. Use standard Windows techniques to change the current directory.

There are four **Save** commands available under the **File** menu in Visual Basic:

Save [Form Name]	Save the currently selected form or module with the current name. The selected file is identified in the Project window.
Save [Form Name] As	Like Save File, however you have the option to change the file name
Save Project	Saves all forms and modules in the current project using their current names and also saves the project file.
Save Project As	Like Save Project, however you have the option to change file names. When you choose this option, if you have not saved your forms or modules, you will also be prompted to save those files. I always use this for new projects.

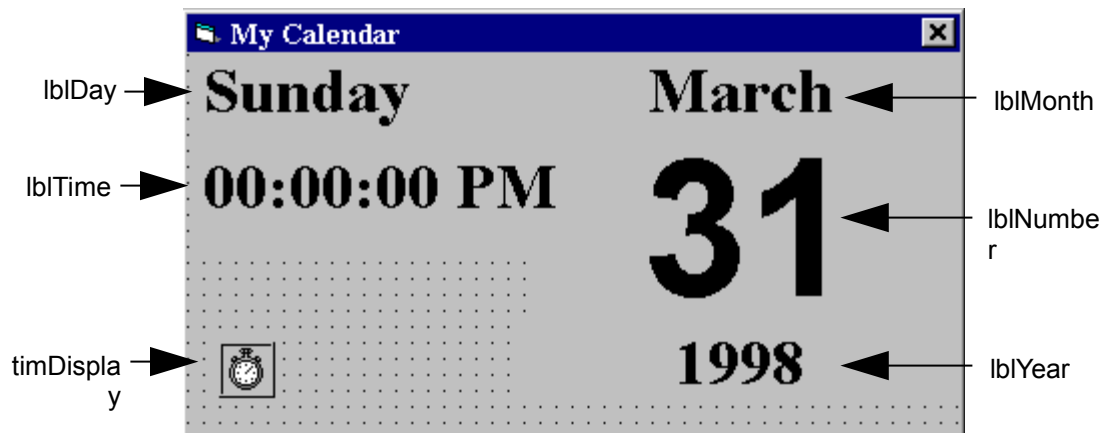

Exercise 1

Calendar/Time Display

Design a window that displays the current month, day, and year. Also, display the current time, updating it every second (look into the **Timer** control). Make the window look something like a calendar page. Play with object properties to make it pretty.

My Solution:

Form:

Properties:

Form **frmCalendar**:

Caption = My Calendar
BorderStyle = 1 - Fixed Single

Timer **timDisplay**:

Interval = 1000

Label **lblDay**:

Caption = Sunday
FontName = Times New Roman
FontBold = True
FontSize = 24

Label lblTime:

Caption = 00:00:00 PM
FontName = Times New Roman
FontBold = True
FontSize = 24

Label lblYear:

Alignment = 2 - Center
Caption = 1998
FontName = Times New Roman
FontBold = True
FontSize = 24

Label lblNumber:

Alignment = 2 - Center
Caption = 31
FontName = Arial
FontBold = True
FontSize = 72

Label lblMonth:

Alignment = 2 - Center
Caption = March
FontName = Times New Roman
FontBold = True
FontSize = 24

Code:**General Declarations:**

```
Option Explicit
```

timDisplay Timer Event:

```
Private Sub timDisplay_Timer()  
Dim Today As Variant  
Today = Now  
lblDay.Caption = Format(Today, "dddd")  
lblMonth.Caption = Format(Today, "mmmm")  
lblYear.Caption = Format(Today, "yyyy")  
lblnumber.Caption = Format(Today, "d")  
lblTime.Caption = Format(Today, "h:mm:ss ampm")  
End Sub
```
