Introduction

TAR is a very popular archiving program in the UNIX world. In a networked heterogeneous computing environment consisting of workstations and PCs which use different file formats, it is desirable to have a single file backup application that can access one type of backup media such as a tape drive.

We all know that backing up files regularly is a good computing practice. Use of tape drives to backup data is very common nowadays. In fact, in a networked computing environment where all workstations are connected together, there is usually at least one tape backup unit. When a PC is connected to such a network, is there any way to backup data from the local hard disk without purchasing a different type of tape drive solely for data backup purpose?

TAR for Windows (WinTAR) can solve this problem for you. WinTAR uses Windows Sockets to communicate with the rest of network. The communication protocol follows that of TCP/IP (Transmission Control Protocol/Internet Protocol) which is another popular networking protocol. Explanation of the operations is beyond the scope of this text, but a few points are summarized here:

- o WinTAR uses port 512 (Remote exec) or port 514 (Remote shell) for data transfer.
- o It relies on the availability of workstations providing UNIX commands or equivalents such as ***dd***, ***mt***, ***tar***, ***gzip***, ***compress***, and ***zcat***. (The last three commands are used if compression is needed.)

Product Highlights

- o User interface to the popular "tar" program in Windows 3.1 and Windows for Workgroup.
- o Can create/open archive files on a local hard disk.
- o Can create/open archive directly on 3.5" 1.44MB floppy diskettes. The disks can directly be read/written on a Sun workstation equipped with 3.5" floppy drives.
- o Can create/open compressed or normal archive files on a remote hard disk.
- o Can create/open archive on any storage medium supported by your workstation.
- o Can manipulate your tape drive (forward, rewind, and "end of media") through icons similar to a cassette tape deck.

System Requirements

The following requirements are needed for WinTAR to run properly:

- o A 386 or above IBM compatible PC with at least 4MB RAM
- o Windows 3.1 or Windows for Workgroup
- o Windows Sockets DLL (such as Trumpet Winsock or Microsoft TCP/IP)
The Winsock DLL can interface to an ethernet card or a modem (using SLIP, PPP, etc.)
or whatever hardware interface that it supports.
- o (Optional) UNIX workstations equipped with storage devices such as tape drives and
availability of services "remote exec" and/or "remote shell".

Installation

Follow the instructions below to install WinTAR:

- 1) Create a directory "c:\wintar" or whatever destination directory you would like WinTAR to install into.
- 2) Unzip wintar.zip in that directory. After unzipping "wintar.zip", you should receive the following files:
 - ctI3dv2.dll
 - licence.txt
 - readme.txt
 - wintar.hlp
 - wintar.ini
 - wintar.exe
- 3) Copy "wintar.ini" into "c:\windows" or any Windows 3.1 installation directory.
- 4) Move "ctI3dv2.dll" into "c:\windows\system" or any Windows 3.1 systems directory. (Remember to delete "ctI3dv2.dll" from your WinTAR installation directory afterwards.)
- 5) In the Program Manager, add "wintar.exe" into any desire application group.
- 6) In "autoexec.bat", add the following line to set up the location of the host database file "host":

```
set RSHHOST_DIR=c:\winsock
```

where "c:\winsock" is the directory that contains the host database file. The host database file follows the format used in the UNIX host database file located in /etc/hosts.
- 6) Double-click the WinTAR icon to start the program up.

Help Menu

[Contents](#)
[About](#)

File Menu

The following items are available in the **File** Menu:

[New Archive](#)
[Open Archive](#)
[Close Archive](#)

New Archive

This item creates an archive. Its options are:

- Local** creates a local archive file on the local hard disk
- Local Floppy** creates a local archive directly on a 3.5" floppy disk. Only 1.44MB HD floppy diskettes are supported.
- Remote** creates a remote archive file on a workstation or writes directly to a storage media such as a tape drive on a remote workstation, depending on the remote command used.

Upon selecting any of the above options, the user will be prompted to select directories, files, and/or drives to backup from. The drive letter is always eliminated in the archive. The user has three options to store the file names:

- Relative to drive: The drive letter together with the first / is dropped, e.g. c:\windows\system\commdlg.dll is converted to windows/system/commdlg.dll.
- Relative to sub-directory: The whole directory tree, except the bottom-most sub-directory, is eliminated, e.g. c:\windows\system\commdlg.dll is converted to system/commdlg.dll.
- Absolute Path: Only the drive letter is eliminated, e.g. c:\windows\system\commdlg.dll is converted to /windows/system/commdlg.dll.

The volume name/template is used to save the current archive selection into a template so that the same set of files/directories can be used in the future. The template name will then be used as the volume name for the archive. This volume header information is compatible with GNU's implementation of TAR. If this entry is empty or if the No volume name in Archive option is enabled, no volume information will be added to the archive. This allows backward compatibility with Sun's TAR utility. The default selection is always default, and this setting cannot be removed or edited. To add a new directory template:

1. Put the files/directories you want to be archived in the Include in Archive list if the list is not already there.
2. Click in the directory template and enter a name for your template.
3. Click the Save Config button to save the template.

To select a predefined template, click on the down arrow button and select the one that you want. The list is then shown in Include in Archive.

When the user has finished the selections, click the OK button, and the user will be prompted for the destination of the archive:

- Local** open a common file saving dialog box to input an archive file name that must end with ".tar"
- Local Floppy** prompts to select a floppy drive to backup to.
- Remote** prompts for the remote host name, user name, and password to access the remote machine. Also shown is the remote command that will be executed after a connection has established. The user can change the command by selecting **Options** button.

During backup, the user can move the WinTAR window around or minimize the window. In addition, if, for any reasons, the user wants to stop the current process, he/she can press the **Stop** button.

After backing up, the user can optionally re-read the archive to verify the archive. Please

note that if you are backing up to a remote tape drive, it takes time for the tape drive to rewind (if you are using a rewinding device). Hence, if you re-read the archive immediately, you may get a device busy error from the remote program.

Open Archive

This item opens an existing archive. Its options are:

- Local** opens a local archive file on the local hard disk
- Local Floppy** opens a local archive directly on a 3.5" floppy disk. Only 1.44MB HD floppy diskettes are supported.
- Remote** opens a remote archive file on a workstation or writes directly to a storage media such as a tape drive on a remote workstation, depending on the remote command used.

Upon selecting any of the above options, the user will be prompted for the source of the archive:

- Local** open a common file opening dialog box to input an archive file name that must end with ".tar"
- Local Floppy** prompts to select a floppy drive to restore from.
- Remote** prompts for the remote host name, user name, and password to access the remote machine. Also shown is the remote command that will be executed after a connection has established. The user can change the command by selecting **Options** button.

Opening an archive only displays a list of files and directories that are available in the archive. This is equivalent to the "-t -v" options in "tar". If the user wants to stop listing the files, he/she can press the **Stop** button. This is especially needed if you are backing up a whole hard disk to a remote tape drive. If the user wants the whole list again, he/she can press the "Re-read archive" button. The user can extract all or a selected list of files/directories from the archive. For the first option, the user simply clicks on the Extract button. For the second option, the user selects one or more files from the file list using the standard file selection convention in Windows applications. (Use Control-Click or Shift-Click to select multiple files.) Then, the user will be prompted for the destination directory.

Please note: any displayed file that has a "/" as the first character will not be placed in the user specified destination directory but in the directory as specified in the file list unless the Force relative directory option is checked.

Close Archive

This item closes the current archive in active.

Options Menu

The following items are available in the **Options** Menu:

[Save Settings on Exit](#)

[Prompt user on all connections](#)

[Log all error messages](#)

[Preferences](#)

[View Log File](#)

[Select Log File](#)

Save Settings on Exit

Checking this item saves the options in the Preference dialog box and other settings.

Prompt user on all connections

Checking this item prompts the user for the host name, user name, and password whenever any commands that require remote connection. When unchecked, the user will be prompted initially for the host name, user name, and password, and any subsequent remote connections will use the same connection information. The remote command will be as shown in the **Advanced** options in the **Preference** section.

Log all error messages

Checking this item logs all messages displayed in the status bar to the log file "wintar.log" located in the WinTAR installation directory. All messages are appended to this file.

Preferences

This item prompts the user for various options that are available for WinTAR:

Option	Meaning
Re-block during reading	is needed on all remote archive connections (-B)
Ignore blocks of zeros	continue even when archive checksum error occurs (-i)
Keep existing files	do not overwrite existing files (-k)
Don't extract file modification time	use the current time as the file modification time (-m)
Extract all protection information	restore the read/write permissions as in the archive (-p)
Use old V7 format	when creating an archive, write an old format archive that does not include information about directories, pipes, or device files. This option is only provided for compatibility for older archives (-o)
Blocking Factor	specify the block size for transferring data to the archive. This is a default value for all local archives. Typically the larger the number, the faster is the transfer time. However, there are a few restrictions depending on the options used and the archiving medium: <i>Floppy drives(R/W)</i> the factor is automatically switched to 18 for the most optimized performance. <i>Local archive file(R/W)</i> can be any number but the suggested value is 20. <i>Remote archive file/tape (R/W)</i> The value is determined from the remote device database. <i>R = reading (extracting), W = writing</i>

Remote commands can be changed via the **Advanced** button.

Advanced Button

Within the **Advanced** button, the following options are available for operations on the remote host:

Option	Meaning
Read command	read (extract) archive
Write command	write archive
Compress command	compress archive on the fly
Decompress command	decompress archive on the fly
Rewind command	rewind tape
End of device command	forward to the end of media
Forward Tape command	forward to next archive command (Use %d to allow this value to be changed)
Tape Status command	retrieve the tape/media information such as the tape drive type
Response Delay	The time between a command being sent to the remote host and a response being received by WinTAR. Sixty seconds is a good value.

For all of the above commands, use "%s" in the command for device name substitution and "%d" in the command for blocking factor substitution. (In the forward tape command, "%d" means the number of archives to advance.)

In addition, a remote device database is also set up in this dialog box. There are two pieces of information shown in the list. The number in square bracket shows the blocking factor while the name on the right shows the device name.

The **Add** button adds new devices/files to the list. When this button is clicked, the user is prompted for a new device name and a blocking factor for that device. The default value is 20.

The **Edit** button changes the value of the currently selected device. This is the same as double clicking any selected device. The user is prompted to change the existing values for the device.

The **Remove** button removes the selected device on the device list.

View Log File

This option is only enabled when a log file exists. This option enables the user to view the logged error messages. The log file is located in your Windows installation directory, by default, with the name wintar.log unless the user has selected a different log file.

Select Log File

This option is used to change the log file to a different name and/or location. Some users prefer the log file to be located somewhere instead of the Windows directory.

Utilities Menu

The following items are available in the **Utilities** Menu:

[Rewind Tape](#)
[Forward Tape](#)
[End of Media](#)
[Eject/Offline Media](#)
[Media Information](#)

Rewind Tape

This item rewinds the tape to the beginning

Forward Tape

This item prompts the user for how many archives to be skipped. The value asked will be substituted into "%d" in the ***Forward Tape command***.

End of Media

This item forwards the tape to the end so that new archives can be added.

Eject/Offline Media

This item ejects a tape on a remote host.

Media Information

This item gets the media type and other information.

Help Menu

The following items are available in the **Help** Menu:

[Contents](#)

[About](#)

Contents

This item displays this help text.

About

This item displays information about WinTAR.

Description of the ToolBar

Most of the frequently used menu items are replicated in the toolbar. When the cursor is above any of the active toolbar buttons, a brief description of the corresponding function is displayed in the status bar at the bottom of the window.

The group of buttons on the left side of WinTAR windows deals with creating, opening, and extracting archives in various locations:

Create archive on local hard disk

Open archive from local hard disk

Create archive on a remote storage device

Open archive on a remote storage device

Create archive on local floppy drive directly

Open archive from local floppy drive directly

Re-read archive list from the opened archive

Extract selected files/directories from the archive. Refer to Open Archive for information about the procedure in extracting files from an archive.

Close archive from an already open archive.

The group of buttons on the right side of WinTAR windows deals with manipulating the tape drive, and they are self explanatory:

Obtain tape information

Eject/Make off-line a remote media

Rewind tape to the beginning

Stop current processing

Forward tape to the next archive

Forward tape to the end of the last archive

Remote Device Access

Whenever the user opens or creates an archive on a remote workstation, he/she is accessing a remote device. After accessing the device, the user is prompted for several pieces of remote access information:

Template:	Specifies a remote access device template. To add a template, fill in all the information below, click in the template box, enter a template name, and click on Save Config button. To select a template, click on the down arrow button, and select the one that you want. Please note that for security reasons, the password is not saved as part of the template. It is however kept in memory for the duration of running WinTAR.
Host name:	The workstation name or IP address to be connected to. Normally a host list is displayed if the environment variable RSHHOST_DIR is set to the directory where the local host data base file hosts exists. Some sites rely on Domain Name Servers (DNS) entirely and do not have a hosts file. In that case, the list would be empty. However, whenever you enter a host name that is not on the host list, you will be asked whether to add the host name to the host list. If you answer Yes, that host name will appear in the host list everytime you are requested to log onto a remote host.
User name:	A valid user name on the network.
Password:	Password for the user. This is used only when the "Remote EXEC" service is used.
Device/File:	A remote device or file to be used. To add a device, you must click the Options button. To use this feature, you must use "%s" instead of a physical device name when setting up the remote commands.
Protocol:	The service protocol to be used. The supported ones are "REXEC" for Remote EXEC (Port 512) and "RSH" for Remote Shell (Port 514).
Compress	Compress the archive on the remote device. This option
Archive:	should not be used for a tape device.
Do not Read	When opening an archive, do not read in the content.
Content:	Checking this option simply changes the current operation state to Open Remote Archive. It does not make any connection to the destination machine.

Trouble-shooting

General

- 1) Upon program startup, WinTAR complains that "CTL3D2V.DLL" is not installed properly.
 - o Is CTL3DV2.DLL in your Windows system directory?
 - o Have you remove CTL3DV2.DLL from your WinTAR installation directory?

Network

- 1) During network connection, WinTAR reports:

a) Connection is aborted due to time-out

- o Is the response delay value large enough? The response delay should be at least 30 seconds.
- o Try to use a network monitoring program such as "ping" to check the connection.

b) Error from network: (Some messages)

- o Please check your UNIX manual pages corresponding to the service protocol for the meaning of the error messages. (The manual pages are rexec(8c) and rshd(8c).)

c) Other time-out messages (From send or receive)

- o Try to use a network monitoring program such as "ping" to check the connection.

2) During any tape operations, WinTAR reports:

a) Cannot receive data from the network (No response). Abort connection ?

- o Is the response delay value large enough? The response delay should be at least 30 seconds.
- o Try to use a network monitoring program such as "ping" to check the connection.
- o With operations like rewind or forward, the response is usually quite slow. You can abort the connection (since the command is still executing on your workstation) You can then check whether the operation is done using the Tape Information command. If the command is done, Tape Information should return the current status of the tape; otherwise, "Device busy" error message should be received.

3) After opening the archive, the user tries to extract some files from archive but nothing is extracted.

- o What type of tape device are you using? (Rewinding or Non-rewinding) A rewinding device rewinds the tape after each device access. A non-rewinding device only rewinds the tape when it is requested.
- o Have you used the forward tape command? If so, you have to, first of all, rewind the tape to the beginning and forward it to the desire archive location again using the forward tape command. Then, you should issue your extract command.

Licensing Information

WinTAR (TAR for Windows)

Copyright (c) 1994 Cheung-Smith Ltd.
All Rights Reserved

You should carefully read the following terms and conditions before using this software.

Shareware Version

You are hereby licensed to: use the Shareware Version of the software for a 21 day evaluation period, make as many copies of the Shareware version of this software and documentation as you wish, give exact copies of the original Shareware version to anyone, and distribute the Shareware version of the software and documentation in its unmodified form via electronic means. There is no charge for any of the above.

You are specifically prohibited from charging, or requesting donations, for any such copies, however made; and from distributing the software and/or documentation with other products (commercial or otherwise) without prior written permission.

Unregistered use of WinTAR after the 21-day evaluation period is in violation of federal copyright laws.

One registered copy of WinTAR may either be used by a single person who uses the software personally on one or more computers, or installed on a single workstation used non-simultaneously by multiple people, but not both. The registered version of WinTAR may not be duplicated other than for backup purposes. A registered copy of WinTAR must be treated like a book, in that the same registered copy of WinTAR may not be used in more than one computer at the same time, just as a book may not be read by more than one person at the same time (without making an illegal copy).

You may access the registered version of WinTAR through a network, provided that you have obtained individual licenses for the software covering all workstations and/or PCs that will access the software through the network.

Governing Law

This agreement shall be governed by the laws of the Province of British Columbia, Canada.

Disclaimer of Warranty

THIS SOFTWARE AND THE ACCOMPANYING FILES ARE SOLD "AS IS" AND WITHOUT WARRANTIES AS TO PERFORMANCE OF MERCHANTABILITY OR ANY OTHER WARRANTIES WHETHER EXPRESSED OR IMPLIED. Because of the variety of hardware and software environments into which WinTAR may be put, **NO WARRANTY OF FITNESS FOR A PARTICULAR PURPOSE IS OFFERED.**

Good data processing procedure dictates that any program be thoroughly tested with non-critical data before relying on it. The user must assume the entire risk of using the program. **ANY LIABILITY OF THE SELLER WILL BE LIMITED EXCLUSIVELY TO PRODUCT REPLACEMENT OR REFUND OF PURCHASE PRICE. NEITHER THE AUTHOR NOR CHEUNG-SMITH LTD. SHALL BE HELD LIABLE FOR ANY KIND OF DAMAGES OR CLAIMS THAT DIRECTLY OR INDIRECTLY RESULT FROM USING THIS SOFTWARE.**

Ordering Information

WinTAR 1.2 Registration Form/Invoice

Ordering by cheque: To order by cheque send this order form and a cheque to:

Cheung Smith Ltd.
211 W63rd Avenue,
Vancouver, B.C.
Canada V5X 2H9

Payments must be in US or Canadian dollars drawn on a Canadian bank, or you can send international postal money orders in Canadian dollars. Please make check payable to **Cheung-Smith Ltd.**. All orders are F.O.B. from the above address. Please allow 4 to 6 weeks for delivery.

Site licenses: a site license for WinTAR entitles an organization to receive one copy of the distribution package and duplicate the distribution disk for the specified number of copies.

WinTAR Single Copy _____ copies at US\$20 (CDN\$25) each = _____
WinTAR Site License
2 to 9 computers: _____ computers at US\$15 (CDN\$20) each = _____
10 to 49 computers: _____ computers at US\$10 (CDN\$15) each = _____
50+ computers: _____ computers at US\$8 (CDN\$12) each = _____

Canadian residents add 7% GST (GST#121104152) + _____
B.C. residents add 7% PST + _____

Total payment _____

Prices guaranteed through December 1994. Prices are calculated in an incremental fashion. For example, to get 11 copies, the first one is US\$20, the second to the ninth ones are US\$15 each, and the tenth and the eleventh ones are US\$10 each, for a total of US\$160.

Method of distribution (Check one only):

- Please send via 3.5" disk by mail.
 Please send via e-mail with address as indicated below. (Most preferable) Only downloading instructions using FTP and product access codes will be sent.

NAME

compress, uncompress, zcat compress or expand files, display expanded contents

SYNOPSIS

compress [**cfv**] [**b** *bits*] [*filename...*]

uncompress [**cv**] [*filename...*]

zcat [*filename...*]

DESCRIPTION

compress reduces the size of the named files using adaptive Lempel-Ziv coding. Whenever possible, each file is replaced by one with the extension **.Z**, while keeping the same ownership modes, as well as access and modification times. If no files are specified, the standard input is compressed to the standard output.

The amount of compression obtained depends on the size of the input, the number of *bits* per code, and the distribution of common substrings. Typically, text such as source code or English is reduced by 50-60%. Compression is generally much better than that achieved by Huffman coding (as used in **sys-unconfig(8)**), or adaptive Huffman coding (**old-compact(1)**), and takes less time to compute. The *bits* parameter specified during compression is encoded within the compressed file, along with a magic number to ensure that neither decompression of random data nor recompression of compressed data is subsequently allowed.

Compressed files can be restored to their original form using **uncompress**.

zcat produces uncompressed output on the standard output, but leaves the compressed **.Z** file intact.

OPTIONS

- c** Write to the standard output; no files are changed. The nondestructive behavior of **zcat** is identical to that of **uncompress**.
- f** Force compression, even if the file does not actually shrink, or the corresponding **.Z** file already exists. Except when running in the background (under **sh(1)**), if **f** is not given, prompt to verify whether an existing **.Z** file should be overwritten.
- v** Verbose. Display the percentage reduction for each file compressed.
- bbits** Set the upper limit (in *bits*) for common substring codes. *bits* must be between 9 and 16 (16 is the default).

SEE ALSO

ln(1V), old-compact(1), sh(1), sys-unconfig(8)

A Technique for High Performance Data Compression, Terry A. Welch, computer, vol. 17, no. 6 (June 1984), pp. 8-19.

DIAGNOSTICS

Exit status is normally 0. If the last file was not compressed because it became larger, the status is 2. If an error occurs, exit status is 1.

Usage: compress [fvc] [bmaxbits] [filename...]

Invalid options were specified on the command line.

Missing maxbits

Maxbits must follow **b**.

filename: **not in compressed format**

The file specified to **uncompress** has not been compressed.

filename: **compressed with xx bits, can only handle yy bits**

filename was compressed by a program that could deal with more bits than the compress code on this machine. Recompress the file with smaller bits.

filename: **already has .Z suffix--nochange**

The file is assumed to be already compressed. Rename the file and try again.

filename: **already exists; do you wish to overwrite (y or n)?**

Respond **y** if you want the output file to be replaced; **n** if not.

uncompress: corrupt input

A SIGSEGV violation was detected, which usually means that the input file is corrupted.

Compression: xx.xx%

Percentage of the input saved by compression. (Relevant only for **v**.)

not a regular file: unchanged

When the input file is not a regular file, (such as a directory), it is left unaltered.

has xx other links: unchanged

The input file has links; it is left unchanged. See **ln(1V)** for more information.

file unchanged

No savings are achieved by compression. The input remains uncompressed.

BUGS

Although compressed files are compatible between machines with large memory, **b12** should be used for file transfer to architectures with a small process data space (64KB or less).

compress should be more flexible about the existence of the **.Z** suffix.

NAME

`dd` convert and copy files with various data formats

SYNOPSIS

`dd [option=value] ...`

DESCRIPTION

`dd` copies a specified input file to a specified output with possible conversions. The standard input and output are used by default. The input and output block size may be specified to take advantage of raw physical I/O.

OPTIONS

if=*name* Input file is taken from *name*; standard input is default.

of=*name* Output file is taken from *name*; standard output is default. Note: **dd** creates an explicit output file; therefore the **seek** option is usually useless with explicit output except in special cases such as using magnetic tape or raw disk files.

ibs=*n* Input block size *n* bytes (default 512).

obs=*n* Output block size *n* bytes (default 512).

bs=*n* Set both input and output block size, superseding **ibs** and **obs**; also, if no conversion is specified, it is particularly efficient since no copy need be done. Block sizes for the Sun386i are 9k for 3.5-inch floppy disks, and 126b (blocks) for quarter-inch tapes.

cbs=*n* Conversion buffer size.

skip=*n* Skip *n* input records before starting copy

files=*n* Copy *n* input files before terminating (makes sense only when input is a magtape or similar device).

seek=*n* Seek *n* records from beginning of output file before copying. This option generally only works with magnetic tapes and raw disk files and is otherwise usually useless if the explicit output file was named with the **of** option.

count=*n* Copy only *n* input records.

conv=

- ascii** Convert EBCDIC to ASCII.
- ebcdic** Convert ASCII to EBCDIC.
- ibm** Slightly different map of ASCII to EBCDIC.
- block** Convert variable length records to fixed length.
- unblock** Convert fixed length records to variable length.
- lcase** Map alphabetic to lower case.
- ucase** Map alphabetic to upper case.
- swab** Swap every pair of bytes.
- noerror** Do not stop processing on an error.
- sync** Pad every input record to **ibs**.

arg,arg [...]

Several comma-separated conversions, for a combination of effects. For instance, **conv=sync,block** is useful for reading variable-length output from a pipe.

Where sizes are specified, a number of bytes is expected. A number may end with **k** (kilobytes) to specify multiplication by 1024, **b** (blocks of 512 bytes) to specify multiplication by 512, or **w** (words) to specify multiplication by 4; a pair of numbers may be separated by **x** to indicate a product.

cbs is used only if **ascii**, **unblock**, **ebcdic**, **ibm**, or **block** conversion is specified. In

the first two cases, **cbs** characters are placed into the conversion buffer, any specified character mapping is done, trailing blanks trimmed and **NEWLINE** added before sending the line to the output. In the latter three cases, characters are read into the conversion buffer, and blanks added to make up an output record of size **cbs**.

After completion, **dd** reports the number of whole and partial input and output blocks.

EXAMPLES

To read an EBCDIC tape blocked ten 80-byte EBCDIC card images per record into the ASCII file *x*:

```
example% dd if=/dev/rmt0 of=x ibs=800 cbs=80 conv=ascii,lcase
```

Note: the use of raw magtape: **dd** is especially suited to I/O on the raw physical devices because it allows reading and writing in arbitrary record sizes.

Sun386i EXAMPLES

The following write the file *filename* to a 3.5-inch floppy and read from the floppy into a file *filename*, respectively:

```
example% dd if=filename of=/dev/rfd0c bs=9k
example% dd if=/dev/rfd0c of=filename bs=9k
```

Sun386i files names are shown in **fdformat(1)**.

SEE ALSO

cp(1), **fdformat(1)**, **tr(1V)**

DIAGNOSTICS

f+p **records in(out):**

Numbers of full and partial records read(written).

BUGS

The ASCII/EBCDIC conversion tables are taken from the 256 character standard in the CACM Nov, 1968. The **ibm** conversion, while less blessed as a standard, corresponds better to certain IBM print train conventions. There is no universal solution.

The **block** and **unblock** options cannot be combined with the **ascii**, **ebcdic** or **ibm**. Invalid combinations silently ignore all but the last mutually-exclusive keyword.

NAME

`gzip`, `gunzip`, `zcat` compress or expand files

SYNOPSIS

```
gzip [acdfhLlNnRrtvV19] [S suffix] [ name ... ]  
gunzip [acfhLlNnRrtvV] [S suffix] [ name ... ]  
zcat [fhLV] [ name ... ]
```

DESCRIPTION

Gzip reduces the size of the named files using Lempel-Ziv coding (LZ77). Whenever possible, each file is replaced by one with the extension **.gz**, while keeping the same ownership modes, access and modification times. (The default extension is **gz** for VMS, **z** for MSDOS, OS/2 FAT, Windows NT FAT and Atari.) If no files are specified, or if a file name is "-", the standard input is compressed to the standard output. *Gzip* will only attempt to compress regular files. In particular, it will ignore symbolic links.

If the compressed file name is too long for its file system, *gzip* truncates it. *Gzip* attempts to truncate only the parts of the file name longer than 3 characters. (A part is delimited by dots.) If the name consists of small parts only, the longest parts are truncated. For example, if file names are limited to 14 characters, `gzip.msdos.exe` is compressed to `gzi.msdx.exe.gz`. Names are not truncated on systems which do not have a limit on file name length.

By default, *gzip* keeps the original file name and timestamp in the compressed file. These are used when decompressing the file with the **N** option. This is useful when the compressed file name was truncated or when the time stamp was not preserved after a file transfer.

Compressed files can be restored to their original form using *gzip -d* or *gunzip* or *zcat*. If the original name saved in the compressed file is not suitable for its file system, a new name is constructed from the original one to make it legal.

gunzip takes a list of files on its command line and replaces each file whose name ends with **.gz**, **-gz**, **.z**, **-z**, **_z** or **.Z** and which begins with the correct magic number with an uncompressed file without the original extension. *gunzip* also recognizes the special extensions **.tgz** and **.taz** as shorthands for **.tar.gz** and **.tar.Z** respectively. When compressing, *gzip* uses the **.tgz** extension if necessary instead of truncating a file with a **.tar** extension.

gunzip can currently decompress files created by *gzip*, *zip*, *compress*, *compress -H* or *pack*. The detection of the input format is automatic. When using the first two formats, *gunzip* checks a 32 bit CRC. For *pack*, *gunzip* checks the uncompressed length. The standard *compress* format was not designed to allow consistency checks. However *gunzip* is sometimes able to detect a bad **.Z** file. If you get an error when uncompressing a **.Z** file, do not assume that the **.Z** file is correct simply because the standard *uncompress* does not complain. This generally means that the standard *uncompress* does not check its input, and happily generates garbage output. The SCO *compress -H* format (lzh compression method) does not include a CRC but also allows some consistency checks.

Files created by *zip* can be uncompressed by *gzip* only if they have a single member compressed with the deflation method. This feature is only intended to help conversion of *tar.zip* files to the *tar.gz* format. To extract *zip* files with several members, use *unzip* instead of *gunzip*.

zcat is identical to *gunzip c*. (On some systems, *zcat* may be installed as *gzcat* to preserve the original link to compress.) *zcat* uncompresses either a list of files on the command line or its standard input and writes the uncompressed data on standard output. *zcat* will uncompress files that have the correct magic number whether they

have a **.gz** suffix or not.

Gzip uses the Lempel-Ziv algorithm used in *zip* and PKZIP. The amount of compression obtained depends on the size of the input and the distribution of common substrings. Typically, text such as source code or English is reduced by 60-70%. Compression is generally much better than that achieved by LZW (as used in *compress*), Huffman coding (as used in *pack*), or adaptive Huffman coding (*compact*).

Compression is always performed, even if the compressed file is slightly larger than the original. The worst case expansion is a few bytes for the gzip file header, plus 5 bytes every 32K block, or an expansion ratio of 0.015% for large files. Note that the actual number of used disk blocks almost never increases. *gzip* preserves the mode, ownership and timestamps of files when compressing or decompressing.

OPTIONS

a --ascii

Ascii text mode: convert end-of-lines using local conventions. This option is supported only on some non-Unix systems. For MSDOS, CR LF is converted to LF when compressing, and LF is converted to CR LF when decompressing.

c --stdout --to-stdout

Write output on standard output; keep original files unchanged. If there are several input files, the output consists of a sequence of independently compressed members. To obtain better compression, concatenate all input files before compressing them.

d --decompress --uncompress

Decompress.

f --force

Force compression or decompression even if the file has multiple links or the corresponding file already exists, or if the compressed data is read from or written to a terminal. If the input data is not in a format recognized by *gzip*, and if the option `--stdout` is also given, copy the input data without change to the standard output: let *zcat* behave as *cat*. If **f** is not given, and when not running in the background, *gzip* prompts to verify whether an existing file should be overwritten.

h --help

Display a help screen and quit.

l --list For each compressed file, list the following fields:

- compressed size: size of the compressed file
- uncompressed size: size of the uncompressed file
- ratio: compression ratio (0.0% if unknown)
- uncompressed_name: name of the uncompressed file

The uncompressed size is given as -1 for files not in gzip format, such as compressed .Z files. To get the uncompressed size for such a file, you can use:

```
zcat file.Z | wc -c
```

In combination with the `--verbose` option, the following fields are also displayed:

- method: compression method
- crc: the 32-bit CRC of the uncompressed data
- date & time: time stamp for the uncompressed file

The compression methods currently supported are deflate, compress, lzsh (SCO compress -H) and pack. The crc is given as ffffffff for a file not in gzip format.

With `--name`, the uncompressed name, date and time are those stored within the compress file if present.

With `--verbose`, the size totals and compression ratio for all files is also displayed, unless some sizes are unknown. With `--quiet`, the title and totals lines are not displayed.

L --license

Display the *gzip* license and quit.

n --no-name

When compressing, do not save the original file name and time stamp by default. (The original name is always saved if the name had to be truncated.) When decompressing, do not restore the original file name if present (remove only the *gzip* suffix from the compressed file name) and do not restore the original time stamp if present (copy it from the compressed file). This option is the default when decompressing.

N --name

When compressing, always save the original file name and time stamp; this is the default. When decompressing, restore the original file name and time stamp if present. This option is useful on systems which have a limit on file name length or when the time stamp has been lost after a file transfer.

q --quiet

Suppress all warnings.

r --recursive

Travel the directory structure recursively. If any of the file names specified on the command line are directories, *gzip* will descend into the directory and compress all the files it finds there (or decompress them in the case of *gunzip*).

S .suf --suffix .suf

Use suffix *.suf* instead of *.gz*. Any suffix can be given, but suffixes other than *.z* and *.gz* should be avoided to avoid confusion when files are transferred to other systems. A null suffix forces *gunzip* to try decompression on all given files regardless of suffix, as in:

```
gunzip -S "" *      (*.*) for MSDOS)
```

Previous versions of *gzip* used the *.z* suffix. This was changed to avoid a conflict with *pack(1)*.

t --test

Test. Check the compressed file integrity.

v --verbose

Verbose. Display the name and percentage reduction for each file compressed or decompressed.

V --version

Version. Display the version number and compilation options then quit.

--fast --best

Regulate the speed of compression using the specified digit *#*, where **1** or **fast** indicates the fastest compression method (less compression) and **9** or **best** indicates the slowest compression method (best compression). The default compression level is **6** (that is, biased towards high compression at expense of speed).

ADVANCED USAGE

Multiple compressed files can be concatenated. In this case, *gunzip* will extract all members at once. For example:

```
gzip -c file1 > foo.gz
```

```
gzip -c file2 >> foo.gz
```

Then

```
gunzip -c foo
```

is equivalent to

```
cat file1 file2
```

In case of damage to one member of a .gz file, other members can still be recovered (if the damaged member is removed). However, you can get better compression by compressing all members at once:

```
cat file1 file2 | gzip > foo.gz
```

compresses better than

```
gzip -c file1 file2 > foo.gz
```

If you want to recompress concatenated files to get better compression, do:

```
gzip -cd old.gz | gzip > new.gz
```

If a compressed file consists of several members, the uncompressed size and CRC reported by the --list option applies to the last member only. If you need the uncompressed size for all members, you can use:

```
gzip -cd file.gz | wc -c
```

If you wish to create a single archive file with multiple members so that members can later be extracted independently, use an archiver such as tar or zip. GNU tar supports the -z option to invoke gzip transparently. gzip is designed as a complement to tar, not as a replacement.

ENVIRONMENT

The environment variable **GZIP** can hold a set of default options for *gzip*. These options are interpreted first and can be overwritten by explicit command line parameters. For example:

```
for sh: GZIP="-8v --name"; export GZIP
```

```
for csh: setenv GZIP "-8v --name"
```

```
for MSDOS: set GZIP=-8v --name
```

On Vax/VMS, the name of the environment variable is GZIP_OPT, to avoid a conflict with the symbol set for invocation of the program.

SEE ALSO

znew(1), zcmp(1), zmore(1), zforce(1), gzexe(1), zip(1), unzip(1), compress(1), pack(1), compact(1)

DIAGNOSTICS

Exit status is normally 0; if an error occurs, exit status is 1. If a warning occurs, exit status is 2.

Usage: gzip [-cdfhLlNnRrtvV19] [-S suffix] [file ...]

Invalid options were specified on the command line.

file: not in gzip format

The file specified to *gunzip* has not been compressed.

file: Corrupt input. Use zcat to recover some data.

The compressed file has been damaged. The data up to the point of failure can be recovered using

```
zcat file > recover
```

file: compressed with *xx* bits, can only handle *yy* bits

File was compressed (using LZW) by a program that could deal with more *bits* than the decompress code on this machine. Recompress the file with *gzip*, which compresses better and uses less memory.

file: already has *.gz* suffix -- no change

The file is assumed to be already compressed. Rename the file and try again.

file already exists; do you wish to overwrite (y or n)?

Respond "y" if you want the output file to be replaced; "n" if not.

gunzip: corrupt input

A SIGSEGV violation was detected which usually means that the input file has been corrupted.

xx.x%

Percentage of the input saved by compression. (Relevant only for **v** and **I**.)

-- not a regular file or directory: ignored

When the input file is not a regular file or directory, (e.g. a symbolic link, socket, FIFO, device file), it is left unaltered.

-- has *xx* other links: unchanged

The input file has links; it is left unchanged. See *ln(1)* for more information. Use the **f** flag to force compression of multiply-linked files.

CAVEATS

When writing compressed data to a tape, it is generally necessary to pad the output with zeroes up to a block boundary. When the data is read and the whole block is passed to *gunzip* for decompression, *gunzip* detects that there is extra trailing garbage after the compressed data and emits a warning by default. You have to use the *--quiet* option to suppress the warning. This option can be set in the **GZIP** environment variable as in:

```
for sh: GZIP="-q" tar -xfz --block-compress /dev/rst0
```

```
for csh: (setenv GZIP -q; tar -xfz --block-compr / dev/rst0
```

In the above example, *gzip* is invoked implicitly by the *-z* option of GNU *tar*. Make sure that the same block size (*-b* option of *tar*) is used for reading and writing compressed data on tapes. (This example assumes you are using the GNU version of *tar*.)

BUGS

The *--list* option reports incorrect sizes if they exceed 2 gigabytes. The *--list* option reports sizes as *-1* and *crc* as *fffffff* if the compressed file is on a non seekable media.

In some rare cases, the *--best* option gives worse compression than the default compression level (*-6*). On some highly redundant files, *compress* compresses better than *gzip*.

NAME

`mt` magnetic tape control

SYNOPSIS

`mt [f tapename] command [count]`

DESCRIPTION

`mt` sends commands to a magnetic tape drive. If *tapename* is not specified, the environment variable **TAPE** is used. If **TAPE** does not exist, `mt` uses the device `/dev/rmt12`. *tapename* refers to a raw tape device. By default, `mt` performs the requested operation once; multiple operations may be performed by specifying *count*.

The available commands are listed below. Only as many characters as are required to uniquely identify a command need be specified.

`mt` returns a 0 exit status when the operation(s) were successful, 1 if the command was unrecognized or if `mt` was unable to open the specified tape drive, and 2 if an operation failed.

OPTIONS

eof,weof	Write <i>count</i> EOF marks at the current position on the tape.
fsf	Forward space over <i>count</i> EOF marks. The tape is positioned on the first block of the file.
fsr	Forward space <i>count</i> records.
bsf	Back space over <i>count</i> EOF marks. The tape is positioned on the beginning-of-tape side of the EOF mark.
bsr	Back space <i>count</i> records.
nbsf	Back space <i>count</i> files. The tape is positioned on the first block of the file. This is equivalent to <i>count+1</i> bsfs followed by one fsf .
asf	Absolute space to <i>count</i> file number. This is equivalent to a rewind followed by a fsf <i>count</i> .

For the following commands, *count* is ignored:

eom	Space to the end of recorded media on the tape. This is useful for appending files onto previously written tapes.
rewind	Rewind the tape.
offline,rewoffl	Rewind the tape and, if appropriate, take the drive unit off-line by unloading the tape.
status	Print status information about the tape unit.
retension	Rewind the cartridge tape completely, then wind it forward to the end of the reel and back to beginning-of-tape to smooth out tape tension.
erase	Erase the entire tape.

FILES

<code>/dev/rmt*</code>	magnetic tape interface
<code>/dev/rar*</code>	Archive cartridge tape interface
<code>/dev/rst*</code>	SCSI tape interface

SEE ALSO

`ar(4S)`, `mtio(4)`, `st(4S)`, `tm(4S)`, `xt(4S)` `environ(5V)`

BUGS

Not all devices support all options. Some options are hardware-dependent. Refer to the corresponding device manual page.

WARNINGS

The **bsf** option for SCSI tape in SunOS 4.0.3 is incompatible with this release and releases prior to 4.0.3.

NAME

rexecd, in.rexecd remote execution server

SYNOPSIS

/usr/etc/in.rexecd host.port

AVAILABILITY

This program is available with the *Networking* software installation option. Refer to **INSTALL** for information on how to install optional software.

DESCRIPTION

rexecd is the server for the **rexec(3N)** routine. The server provides remote execution facilities with authentication based on user names and encrypted passwords. It is invoked automatically as needed by **inetd(8C)**, and then executes the following protocol:

- o The server reads characters from the socket up to a null (**\0**) byte. The resultant string is interpreted as an ASCII number, base 10.
- o If the number received in step 1 is non-zero, it is interpreted as the port number of a secondary stream to be used for the **stderr**. A second connection is then created to the specified port on the clients machine.
- o A null terminated user name of at most 16 characters is retrieved on the initial socket.
- o A null terminated, encrypted, password of at most 16 characters is retrieved on the initial socket.
- o A null terminated command to be passed to a shell is retrieved on the initial socket. The length of the command is limited by the upper bound on the size of the systems argument list.
- o **rexecd** then validates the user as is done at login time and, if the authentication was successful, changes to the users home directory, and establishes the user and group protections of the user. If any of these steps fail the connection is aborted with a diagnostic message returned.
- o A null byte is returned on the connection associated with the **stderr** and the command line is passed to the normal login shell of the user. The shell inherits the network connections established by **rexecd**.

SEE ALSO

rexec(3N) **inetd(8C)**,

DIAGNOSTICS

All diagnostic messages are returned on the connection associated with the **stderr**, after which any network connections are closed. An error is indicated by a leading byte with a value of 1 (0 is returned in step 7 above upon successful completion of all the steps prior to the command execution).

username too long

The name is longer than 16 characters.

password too long

The password is longer than 16 characters.

command too long

The command line passed exceeds the size of the argument list (as configured into the system).

Login incorrect.

No password file entry for the user name existed.

Password incorrect.

The wrong password was supplied.

No remote directory.

The **chdir** command to the home directory failed.

Try again.

A **fork** by the server failed.

/usr/bin/sh:...

The users login shell could not be started.

BUGS

Indicating **Login incorrect** as opposed to **Password incorrect** is a security breach which allows people to probe a system for users with null passwords.

A facility to allow all data exchanges to be encrypted should be present.

NAME

rshd, in.rshd remote shell server

SYNOPSIS

/usr/etc/in.rshd host.port

DESCRIPTION

rshd is the server for the **rcmd**(3N) routine and, consequently, for the **rsh**(1C) program. The server provides remote execution facilities with authentication based on privileged port numbers.

rshd is invoked by **inetd**(8C) each time a shell service is requested, and executes the following protocol:

- o The server checks the clients source port. If the port is not in the range 512-1023, the server aborts the connection. The clients host address (in hex) and port number (in decimal) are the argument passed to **rshd**.
- o The server reads characters from the socket up to a null (**\0**) byte. The resultant string is interpreted as an ASCII number, base 10.
- o If the number received in step 1 is non-zero, it is interpreted as the port number of a secondary stream to be used for the **stderr**. A second connection is then created to the specified port on the clients machine. The source port of this second connection is also in the range 512-1023.
- o The server checks the clients source address. If the address is associated with a host for which no corresponding entry exists in the host name data base (see **hosts**(5)), the server aborts the connection.
- o A null terminated user name of at most 16 characters is retrieved on the initial socket. This user name is interpreted as a user identity to use on the **servers** machine.
- o A null terminated user name of at most 16 characters is retrieved on the initial socket. This user name is interpreted as the user identity on the **clients** machine.
- o A null terminated command to be passed to a shell is retrieved on the initial socket. The length of the command is limited by the upper bound on the size of the systems argument list.
- o **rshd** then validates the user according to the following steps. The remote user name is looked up in the password file and a **chdir** is performed to the users home directory. If the lookup or fails, the connection is terminated. If the **chdir** fails, it does a **chdir** to / (**root**). If the user is not the super-user, (user ID 0), the file **/etc/hosts.equiv** is consulted for a list of hosts considered ***(l|equivalent)*(r|q**. If the clients host name is present in this file, the authentication is considered successful. If the lookup fails, or the user is the super-user, then the file **.rhosts** in the home directory of the remote user is checked for the machine name and identity of the user on the clients machine. If this lookup fails, the connection is terminated.
- o A null byte is returned on the connection associated with the **stderr** and the command line is passed to the normal login shell of the user. The shell inherits the network connections established by **rshd**.

FILES

/etc/hosts.equiv

SEE ALSO

rsh(1C), rcmd(3N), syslogd(8)

BUGS

The authentication procedure used here assumes the integrity of each client machine and the connecting medium. This is insecure, but is useful in an open environment.

A facility to allow all data exchanges to be encrypted should be present.

DIAGNOSTICS

The following diagnostic messages are returned on the connection associated with the **stderr**, after which any network connections are closed. An error is indicated by a leading byte with a value of 1 (0 is returned in step 9 above upon successful completion of all the steps prior to the command execution).

locuser too long

The name of the user on the clients machine is longer than 16 characters.

remuser too long

The name of the user on the remote machine is longer than 16 characters.

command too long

The command line passed exceeds the size of the argument list (as configured into the system).

Hostname for your address unknown.

No entry in the host name database existed for the clients machine.

Login incorrect.

No password file entry for the user name existed.

Permission denied.

The authentication procedure described above failed.

Cant make pipe.

The pipe needed for the **stderr**, was not created.

Try again.

A *fork* by the server failed.

/usr/bin/sh:...

The users login shell could not be started.

In addition, daemons status messages and internal diagnostics are logged to the appropriate system log using the **syslogd(8)** facility.

NAME

`tar` create tape archives, and add or extract files

SYNOPSIS

`tar [] c|r|t|u|x [bBefFhilmopvwX014578] [tarfile] [blocksize] [exclude-file] [include-file] filename1 filename2 ... C directory filenameN ...`

DESCRIPTION

`tar` archives and extracts multiple files onto a single `tar`, file archive, called a *tarfile*. A *tarfile* is usually a magnetic tape, but it can be any file. `tar`'s actions are controlled by the first argument, the key, a string of characters containing exactly one function letter from the set `crtux`, and one or more of the optional function modifiers listed below. Other arguments to `tar` are file or directory names that specify which files to archive or extract. In all cases, the appearance of a directory name refers recursively to the files and subdirectories of that directory.

FUNCTION LETTERS

- c** Create a new *tarfile* and write the named files onto it.
- r** Write the named files on the end of the *tarfile*. Note: this option does not work with quarter-inch archive tapes.
- t** List the table of contents of the *tarfile*.
- u** Add the named files to the *tarfile* if they are not there or if they have been modified since they were last archived. Note: this option *does not work* with quarter-inch archive tapes.
- x** Extract the named files from the *tarfile*. If a named file matches a directory with contents written onto the tape, this directory is (recursively) extracted. The owner, modification time, and mode are restored (if possible). If no *filename* arguments are given, all files in the archive are extracted. Note: if multiple entries specifying the same file are on the tape, the last one overwrites all earlier versions.

FUNCTION MODIFIERS

- b** Use the next argument as the blocking factor for tape records. The default blocking factor is 20 blocks. The block size is determined automatically when reading tapes (key letters `x` and `t`). This determination of the blocking factor may be fooled when reading from a pipe or a socket (see the **B** key letter below). The maximum blocking factor is determined only by the amount of memory available to `tar` when it is run. Larger blocking factors result in better throughput, longer blocks on nine-track tapes, and better media utilization.
- B** Force `tar` to perform multiple reads (if necessary) so as to read exactly enough bytes to fill a block. This option exists so that `tar` can work across the Ethernet, since pipes and sockets return partial blocks even when more data is coming.
- e** If any unexpected errors occur `tar` will exit immediately with a positive exit status.
- f** Use the next argument as the name of the *tarfile*. If `f` is omitted, use the device indicated by the **TAPE** environment variable, if set. Otherwise, use `/dev/rmt8` by default. If *tarfile* is given as `,` `tar` writes to the standard output or reads from the standard input, whichever is appropriate. Thus, `tar` can be used as the head or tail of a filter chain. `tar` can also be used to copy hierarchies with the command:

example% cd fromdir; tar cf . | (cd todir; tar xfbp)

- F** With one **F** argument specified, exclude all directories named SCCS from *tarfile*. With two arguments **FF**, exclude all directories named SCCS, all files with **.o** as their suffix, and all files named **errs**, **core**, and **a.out**.
- h** Follow symbolic links as if they were normal files or directories. Normally, **tar** does not follow symbolic links.
- i** Ignore directory checksum errors.
- I** Display error messages if all links to archived files cannot be resolved. If **I** is not used, no error messages are printed.
- m** Do not extract modification times of extracted files. The modification time will be the time of extraction.
- o** Suppress information specifying owner and modes of directories which **tar** normally places in the archive. Such information makes former versions of **tar** generate an error message like:
filename/:cannotcreate
when they encounter it.
- p** Restore the named files to their original modes, ignoring the present **umask(2V)**. SetUID and sticky information are also extracted if you are the super-user. This option is only useful with the **x** key letter.
- v** Verbose. Normally **tar** does its work silently; this option displays the name of each file **tar** treats, preceded by the function letter. When used with the **t** function, **v** displays the *tarfile* entries in a form similar to **ls l**.
- w** Wait for user confirmation before taking the specified action. If you use **w**, **tar** displays the action to be taken followed by the file name, and then waits for a **y** response to proceed. No action is taken on the named file if you type anything other than a line beginning with **y**.
- X** Use the next argument as a file containing a list of named files (or directories) to be excluded from the *tarfile* when using the key letters **c**, **x**, or **t**. Multiple **X** arguments may be used, with one *exclude file* per argument.

014578

Select an alternate drive on which the tape is mounted. The numbers **2**, **3**, **6**, and **9** do not specify valid drives. The default is **/dev/rmt8**.

If a file name is preceded by **I** then the filename is opened. A list filenames, one per line, is treated as if each appeared separately on the command line. Be careful of trailing white space in both include and exclude file lists.

In the case where excluded files (see **X** option) also exist, excluded files take precedence over all included files. So, if a file is specified in both the include and exclude files (or on the command line), it will be excluded.

.ne "6"

If a file name is preceded by **C** in a **c** (create) or **r** (replace) operation, **tar** will perform a **chdir** (see **chsh(1)**) to that file name. This allows multiple directories not related by a close common parent to be archived using short relative path names. See EXAMPLES below.

Note: the **C** option only applies to *one* following directory name and one following file name.

EXAMPLES

To archive files from `/usr/include` and from `/etc`, one might use:

```
example% tar c C /usr include C /etc .
```

If you get a table of contents from the resulting *tarfile*, you will see something like:

```
include/
include/a.out.h
and all the other files in /usr/include...
/chown
and all the other files in /etc
```

Here is a simple example using **tar** to create an archive of your home directory on a tape mounted on drive `/dev/rmt0`:

```
example% cd
example% tar cvf /dev/rmt0 .
messages from tar
```

The **c** option means create the archive; the **v** option makes tar tell you what it is doing as it works; the **f** option means that you are specifically naming the file onto which the archive should be placed (`/dev/rmt0` in this example).

Now you can read the table of contents from the archive like this:

```
example% tar tvf /dev/rmt0    display table of contents of the archive
(access user-id/group-id  size  mod. date      filename)
rw-r--r-- 1677/40          2123  Nov 7 18:15:1985  ./archive/test.c
...
example%
```

You can extract files from the archive like this:

```
example% tar xvf /dev/rmt0    extract files from the archive
messagesfromtar
example%
```

If there are multiple archive files on a tape, each is separated from the following one by an EOF marker. **tar** does not read the EOF mark on the tape after it finishes reading an archive file because **tar** looks for a special header to decide when it has reached the end of the archive. Now if you try to use **tar** to read the next archive file from the tape, **tar** does not know enough to skip over the EOF mark and tries to read the EOF mark as an archive instead. The result of this is an error message from **tar** to the effect:

```
tar: blocksize=0
```

This means that to read another archive from the tape, you must skip over the EOF marker before starting another **tar** command. You can accomplish this using the **mt(1)** command, as shown in the example below. Assume that you are reading from `/dev/nrmt0`.

```
example% tar xvfp /dev/nrmt0  read first archive from tape
messages from tar
example% mt fsf1              skip over the end-of-file marker
example% tar xvfp /dev/nrmt0  read second archive from tape
messages from tar
example%
```

Finally, here is an example using **tar** to transfer files across the Ethernet. First, here is how to archive files from the local machine (**example**) to a tape on a remote system

(host):

```
example% tar cvfb 20 filenames | rsh host dd of=/dev/rmt0 obs=20b
messages from tar
example%
```

In the example above, we are *creating* a *tarfile* with the **c** key letter, asking for *verbose* output from **tar** with the **v** option, specifying the name of the output *tarfile* using the **f** option (the standard output is where the *tarfile* appears, as indicated by the **o** sign), and specifying the blocksize (20) with the **b** option. If you want to change the blocksize, you must change the blocksize arguments both on the **tar** command and on the **dd** command.

Now, here is how to use **tar** to get files from a tape on the remote system back to the local system:

```
example% rsh n host dd if=/dev/rmt0 bs=20b | tar xvBfb 20
filenames
messages from tar
example%
```

In the example above, we are *extracting* from the *tarfile* with the **x** key letter, asking for *verbose* output from **tar** with the **v** option, telling **tar** it is reading from a pipe with the **B** option, specifying the name of the input *tarfile* using the **f** option (the standard input is where the *tarfile* appears, as indicated by the **o** sign), and specifying the blocksize (20) with the **b** option.

FILES

/dev/rmt? half-inch magnetic tape interface
/dev/rst? SCSI tape interface
/tmp/tar*

ENVIRONMENT

TAPE If specified, in the environment, the value of **TAPE** indicates the default tape device.

SEE ALSO

BUGS

Neither the **r** option nor the **u** option can be used with quarter-inch archive tapes, since these tape drives cannot backspace.

There is no way to ask for the *n*th occurrence of a file.

Tape errors are handled ungracefully.

The **u** option can be slow.

There is no way selectively to follow symbolic links.

When extracting tapes created with the **r** or **u** options, directory modification times may not be set correctly.

Files with names longer than 100 characters cannot be processed.

Filename substitution wildcards do not work for extracting files from the archive. To get around this, use a command of the form:

```
tar xvf ... /dev/rst0 tar tf ... /dev/rst0 | grep pattern
```
